during which we were for nine months subject to competition was not altogether disastrous. We laid aside a goodish bit of money, paid a reasonable dividend for the year, and entered on the second year; and I am bound to say that during the second year the accentuation of the competition and the wider area over which it has been spread, and the greater number of people who have come into the business hoping to make a fortune out of it, have made the position more difficult. We have ourselves during that time learnt a great deal to our advantage and to your advantage, and I do not think we are very much alarmed at our prospects. Of course, we shall have to face a considerable reduction in the price of the article we sell under competition, but the satisfactory feature of the past year's trading seems to be that the character of the Company and the character of the lamp has enabled us, notwithstanding the severity of the competition, not only to maintain our position, but, as regards the volume of the output, to improve it. We have sold more lamps and other things during the past year than in the preceding one, but inasmuch as for three months of the preceding year the old prices were charged, the money results of the period under review, as you would expect to find, are altered, but they still leave such a margin of profit as makes the payment of a 5 per cent. dividend for the year perfectly easy, rational, and wise. More than that, we carry forward something, and we have charged the working of the undertaking with reasonably fair sums for depreciation of the value of the plant, buildings, stock, and so forth. We have tried to keep the Company in a wholesome position. Now, with this little preliminary explanation, I will refer you to the very simple figures of the accounts. They are in exactly the same form as you have always had them before you, and they are so simple and easy to comprehend that I suppose in five minutes any of you gentlemen could make yourself master of the features of the thing. You cannot, of course, probe into the hundreds and thousands of figures which make up these in the accounts, but you will gather from these the general results which I have indicated—that our position has been maintained and, in fact, improved. Our business is now a solid one, and the Company has a very good character, so that there is every likelihood that it will be extended. People have their preferences, and it is characteristic of the English people that they are very fond of their old favourites, and, if they are wise, they stick to them. We hope they will stick to us. We happily find that our customers are doing so, and that some who were tempted by the alluring prospect of getting a lamp at half, or less than half, the old price, after having tried it, are coming back to us. As you will see by the profit and loss account, we began the year with a stock on hand valued at £87,768, and, as shown on the opposite side of the account, we ended it with the stock increased to £95,983. I will explain the reason why presently. Then wages, purchases, &c., amount to £85,112. Of course we manufacture largely ourselves. We purchase some things partly manufactured and some wholly manufactured, and that item covers the amount paid for material, wages and supervision in the workshops, and for the purchase of those articles which, either in a partly complete or wholly complete state, we find it more prudent to buy because we are able to do so cheaper than we can ourselves make them. Salaries, Directors' renumeration, rent, office expenses, &c., figure at £10,759, and depreciation on plant at £3,512. These are the items of outgoing, and you will see the depreciation on plant is a considerable item. That is a repetition of sums set aside year after year from the commencement of the business, and which in the aggregate have amounted to a very large figure, which has been written off the original cost of the plant, so that it stands in our books at a good deal less than it has cost. Then, on the other side of the account, you will see that the sum obtained by sale of lamps, fittings, royalty on holders, &c., is £114,890, and interest £2,156. Then there is a balance of £25,876 over and above the outgoings, and this enables you to be paid the proposed 5 per cent. dividend, after having paid the relatively new charge on the Company of £100,000 Four and a-Half per Cent. Debentures, which represents the purchase-money of the Swan residuum. Those who were here when the purchase was explained, will remember that we have taken over the foreign business, assets, character, &c., of the Swan Company, and the Edison and Swan Companies are consequently now being worked as one undertaking. There is a considerable advantage about that. All the separate expenditure of that Company was saved, and one of the benefits to us of the transaction was that it made us free of the difficulties which attended our export business to the Continent, because the agreement with the Swan Company was that they should only put in their British patents with the Edison here, and that we were precluded from selling lamps for the Continent of Europe, and, indeed, of exporting them without their consent. Well, that bargain we made over to the French Company, with whom we were united, and it was really the feeling of disadvantage of that bargain which made us anxious to bring back the sheep into the fold, one of the incidents being dissolution, so far as we were concerned, of the French Company. We sold out our interest to them, and got back a considerable asset in money; and we were also released for all time from the restrictions which previously existed, and obtained perfect freedom to export our lamps to the continent of Europe and every other part of the world. The balance sheet, I think, stands pretty nearly as it did at the last meeting, as far as the essential figures go. There is the share capital of different denominations, and the £100,000 of Four and a-Half per Cent. Debenture Stock, sundry credit balances, the reserve fund, and so forth. On the other side you will find the old figures—cost of establishing the business, goodwill, remaining patents, &c., £261,955, with the item "further expenditure thereon, £19,307," which I will explain, because if one did not explain it you might think there was some object in not doing so. That makes our charge, supposing we were in the position of a company liquidating, as £262,000 in round numbers to be accounted for against the share capital and the £100,000 of debentures. We have a sleeping partner in the concern, and the "B" shares represent the interest which Mr. Edison and his friends hold in this Company in virtue of their having been patentees and the original people who constituted the Company. The shares are made subject to a 7 per cent. dividend being paid on the other shares. When the happy moment arrives at which 7 per cent. is payable—and it has been paid for a good many years—and there is a surplus, these gentlemen are entitled to participate in it to the extent of one quarter. Any deficiency in paying the "A" shareholders has to be wiped out before the "B" shareholders can touch any of the profits earned. Well, that £19,000 odd I was speaking about is this: When we went into the French combination we raised a particular capital—2,000,000fr., and that was contributed on two principles. 1,000,000fr. was the assumed value of the patents put into the pot by the Edison and the Swan Companies; the other 1,000,000fr. was subscribed in cash to start the business and conduct it. We went on, as you know, for a considerable number of years under the contract, and the question that arose at the expiration of that contract by effluxion of time was whether it should be renewed or determined by mutual consent. Our French colleagues were not very sweet about going on, neither were we, principally for the reason that our experience showed us that any benefit we could get from the investment of that money in France was very dearly purchased by our being excluded, under the contract, from the rest of Europe, and also from exporting to our Colonies and the rest of the world. Therefore we thought it better to get out of it. The ideal proportion in respect of goodwill, &c., comes back. It was never represented in hard cash, and we have it for what it is worth for the whole of Europe. The cash we got back a considerable portion of—about £12,000 out of £15,000—and that is the price at which we have become free and unencumbered as regards our French partners, and there is more an imaginary than a real addition to the expenditure of our undertaking in this £19,000. That is the outcrop of the operation. Part of it, representing some £15,000, was the book value of the goodwill, and the other was the balance of the £15,000 paid in cash, which had been diminished to some extent in the course of the operation of the business. There is another item—freehold and leasehold property—which I may say a word of explanation about, and I refer to it to anticipate any question that may be asked as to the diminution in our reserves of cash. One knows perfectly well how valuations of property connected with a company of this kind works—how much the value of the plant, machinery, &c., depends on its being a going concern. If you equip a factory, put plant into it and everything else you require to start a particular business, and it fails, the probability is that that factory, with all its appurtenances, is not worth so much to a purchaser for some other purpose as it is to you, and as it cost you to make it applicable to certain purposes; and, therefore, one has to proceed in such a case as you would do in opening a shop or a set of offices—namely, that the original outlay being a necessary thing, it has to be recouped by the profits from the business. That has been done with regard to our property. The primitive figures have been much reduced out of our profits. The additional part of the item is the leasehold property. I do not know whether the proprietors ever care to see where their property is. If they do, and will walk round to Queen-street, they will see what an admirable building we have there, in a capital position for our business; and if they will be good enough to call on the secretary he will enable them to see how admirably it is laid out for the conduct of our business, including, as it does, sale rooms, store rooms, and the necessary offices and appurtenances for what is, after all, a considerable administration. It involves a large establishment to conduct a business like ours. We are obliged to watch with a good deal of vigilance and carefully check the cost, even to a very trifling sum, the goods that we manufacture. For instance, suppose we say an article cost 6¼d.: well, that farthing is a most essential element in the matter, and it is worth a good deal to prove that that farthing is a superfluity, and should not be spent. This is a business in which the figures will run into millions in the course of time. One has only to appreciate what a million of farthings amounts to to see the importance of reducing the cost of manufacturing our articles by every fraction that it is possible to do. The next item is plant and stock, which together comes to £132,260. That includes all the plant in our several factories, and the great number of depots we have got, and also the lamps and fittings we have for sale, and also a variety of things, platinum and so forth, which, at the end of every half-year, has to be accounted for. I have remarked several times that that looks a large amount in the aggregate, and would be so if we had only one depot. But we have besides the depot in the City, another at Westminster, and others in 12 of the principal cities of Great Britain, each of which has to be stocked with a great number of appliances. If you walk to our Queen-street depot after this meeting, you will see there innumerable articles which have to be kept in stock to show to people who come to select their electrical fittings. That means a large lock-up of money, and a business of this kind cannot be conducted without a considerable lock-up. As I have said before, we have not anything to fear from small companies. Any serious competitor in this business must be people armed with a great deal of capital. There must be a great deal of money expended before you are able to give your customers a wide choice, which is what they expect. People will not come to us to buy a lamp if they have to go elsewhere for the holders and fittings, and so we have to keep a great variety of lamps and everything else in stock in order to prevent customers going elsewhere. Then we have some debtors, which amount to £41,609. I suppose that so far as anyone can say a thing is absolute that that sum is absolutely good, and as you will see, it exceeds our credit balances, which are, in fact, our debts, by about £10,000. Then we have a sum of £25,000 invested in the National Telephone Company Five per Cent. Non-cumulative Third Preference shares. I believe the price in the market is quite the amount at which they stand in the balance sheet—perhaps a little more. These are the items in the balance sheet, and except for the purpose of answering any questions or elucidating further any point, I think I need say no more about them. Then, of course, we come to the dividend. The third account shows how we

Digitized by Google

propose to appropriate the profits. Of course, we are bound to make the payments of interest on the Debenture stock as they become due on January 1st and July 1st, and that has been done. We paid an interim dividend in respect of the business of the half-year ended December 31st last at the rate of 5 per cent., and we propose to pay you now a further dividend at the rate of 5 per cent. for the past six months, making 5 per cent. for the year, and leaving £3,702 to be carried forward. To sum it all up I may say that notwithstanding severe competition and the natural desire of prudent people to substitute a cheaper article for a dearer one until they learn that cheapness is not always economy, we have been able to maintain our position. I think we have improved our character and learnt a good deal, and we know now, no doubt a great deal more accurately the wants of the public under competition than we knew before, and the volume of our business has increased, although the receipts have diminished in consequence of the price having fallen. As far as my colleagues and myself can judge—and we are bound to give you the benefit of our convictions—we believe this business is established now on a fair and solid basis, and is calculated to yield a pretty fair dividend, and will in the course of time become more lucrative than it is now. With these remarks I beg to move—

"*That the report and accounts for the year ended June 30, 1895, be received and adopted.*"

The EARL of LICHFIELD seconded the resolution.

Mr. K. W. HEDGES recommended the immediate publication of a catalogue, and of curves showing the superiority of Edison-Swan lamps over others.

The CHAIRMAN: The Directors think we may rest on the fact that most of our customers who have tried other people's lamps come back to us, but Mr. Hedge's suggestions will have our best consideration, if we can get them presented in an intelligible form. With regard to the complaint that we have no catalogue, I should explain that this is taking a new form. As soon as our patents expired and we opened shops, we found ourselves bound to go in for holders of many types, and to compete with firms who for years have had the great advantage that artistic taste in the fitting up of our houses with gas fittings gave them in adapting those things to electric lighting. To us that was a new business, and we have had to get the machinery together and form a staff. The catalogue is in the press.

The adoption of the report was then agreed to unanimously, as were the dividends announced in the report.

The Earl of Lichfield and Mr. Ernest Villiers were re-elected Directors, and Messrs. Welton, Jones and Co. as auditors.

The CHAIRMAN then referred to the next business—the proposed alteration in the Memorandum of Association, set out on page 438 of our last issue, the import of which was explained to the meeting by Mr. Crisp, the Company's solicitor, after which

Mr. G. BLACK said he did not think the proposal a fair one to the Edison fully-paid shareholders, as the payment of 2s. 6d. was not a sufficient equivalent for what they were asked to give up, and if this resolution were passed over his head he should consider if he could not take steps to prevent it from being carried out.

The CHAIRMAN said that 98 shareholders, representing 4,800 shares, had consented to this proposal in order to get a Stock Exchange quotation, and here was Mr. Black and his friend standing out, one representing 12 and the other 63 shares. It was not reasonable that the undoubted advantages to the shareholders as a body of a Stock Exchange quotation was to be upset in this manner. They had had cases of shareholders having to part with their fully-paid Swan or Edison shares at a price below that which they could get for the shares with £3. 10s. paid, because the £3. 10s. shares were quoted on the Stock Exchange.

The EARL of LICHFIELD made a special appeal to Mr. Black to consent to the proposed agreement, as it was to the interest of all the Edison fully-paid shareholders to do so.

Mr. BLACK said after what had taken place he would not press his objection further.

The motion for the alteration of the Memorandum having been put to the meeting and approved,

A vote of thanks to the Chairman and the Board brought the proceedings to a close.

Eastern Telegraph Company (Limited).

The forty-sixth half-yearly general meeting of the Eastern Telegraph Company (Limited) was held on Thursday, July 25, 1895, at Winchester House, 50, Old Broad-street, London, under the presidency of the Most Hon. the Marquis of Tweeddale, the Vice-Chairman.

The SECRETARY read the notice convening the meeting, and the minutes of the last half-yearly general meeting.

The CHAIRMAN, having signed the minutes, said: I have now to move the adoption of the report and accounts, which you have had in your hands some days, and which you will probably take as read. Before actually making the motion I feel it right to explain that we were under the necessity of holding this meeting a few days later than usual, but this will not occur again, and next year you may calculate upon the meeting being held at the usual time. I have also to mention that our Chairman is unavoidably absent to-day. This is polling day at the Wick Burghs, and I am sure you will all join in expressing the hope that he may accomplish what he is so anxious to achieve. This is our forty-sixth meeting, and Sir John Pender has presided on every occasion excepting this one. I know he regrets his absence very much, as he takes a particular pleasure in being present at the half-yearly meetings of the Company whose prosperity owes so much to his energy and ability.

I propose to follow the example which he sets on these occasions, giving you a few observations on the accounts and the report. The gross revenue for the half-year under review amounted to £420,526, being an increase of £31,212 on that of the corresponding period of 1894. On an examination of the message receipts from all sources we find a small decrease in the traffic with India, but a considerable increase in the traffic beyond India, to Australia and China. There is also a marked increase in the traffic with South Africa, no doubt owing to the activity in mining business which has prevailed there for so long. You will remember that the Chairman at the last general meeting announced that the Eastern and South African Telegraph Company (in which this Company is largely interested) was about to complete an arrangement with the Governments of Great Britain, the Cape of Good Hope, Natal, and the South African Republic, as well as with the British South Africa Company, for a continuation of a portion of the subsidies now payable for telegraphic communication with South Africa, in consideration of a reduction of the tariff over the Associated Companies' lines between Europe and South Africa. Those negotiations were brought to a satisfactory conclusion; and here I may perhaps read a telegram which I received from Sir John Pender a minute or two ago, in which he says how much he regrets not being present at the meeting to-day, and adds, "You can tell the shareholders that arrangements just completed with the Cape, Natal and the Transvaal, insure us 15 years' prosperity." The rates were reduced from 8s. 9d. to 5s. per word for public telegrams, and from 2s. 2½d. to 1s. 6d. per word for Press telegrams. The accounts which are submitted to you to-day are, of course, not affected by the reductions, but the result so far may be considered satisfactory to all the parties to the agreement as well as to the telegraphing public.

Looking at the ordinary expenses of the half-year we find that they amounted to £98,060, or an increase of £3,220. From this increase, however, must be deducted about £2,293 for proportion of stationery charged against this half-year's accounts. This has been fully explained at the last two general meetings. The present half-year's is charged with its proper proportion of the annual supply. The comparisons between one half-year with another will in future be easily made, as each period will bear its proper share of the annual cost. The actual increase in the ordinary expenses is therefore only about £927, and this notwithstanding a very large increase in the number of messages dealt with. This increase, I may mention, amounts in words to half a million, and in messages to very nearly 100,000.

Looking now to the working expenses at the stations, you will find that they amount to £81,220, being an increase, compared with those of the corresponding period of 1894, of £4,579; but, deducting the item for stationery just referred to, the increase under this head amounts to only £1,396. This is mainly due to the salaries and allowances of the increased number of staff required to deal with the additional traffic, and also to the annual promotions to the other members of the staff. For instance, the number of the staff at the stations in March, 1895, was 729, whereas in March, 1894, the number was 714, so that there is an increase this year of 15. You are, I believe, aware that we take great pains to make our employés, wherever they may happen to be stationed, as comfortable as possible. We pay them good salaries, and provide them with means of recreation both indoors and out. In return for that we look for active and zealous discharge of their duties, and we have not been disappointed (hear, hear). I question if any service can show a body of men more animated with a desire to do their duty and carry out the wishes of their employers than the men in our service.

The expenses attending repairs and renewals of cables amounted to £52,730, or an increase of £3,070. Full details of the work done by our ships during the half-year will be found on page 6, Abstract "C." You will find there that they have been very actively employed—more than in the preceding year. The ordinary expenses of the ships this half-year amounted to about the same figure as they did in the corresponding period of 1894, notwithstanding that they were, as I have just said, more actively employed during the half-year under review. The credits received from other companies for the hire of our ships show an increase of £8,000, so that the increased expenses attending repairs to cables are due to our having laid an exceptionally large quantity of new cable into the original Aden-Bombay section. During the last 18 months we have laid in about 300 miles of new cable. You will be glad to know that this section, laid so far back as 1870, is, with these repairs, now in good working order. This section, you will notice, is 25 years old.

Under the head of depreciation of spare cable we find that there is an amount of £3,222, or an increase of £844 as compared with the same item in the corresponding period of 1894. This item necessarily depends on the amount of the stock of cable in the tanks from time to time, but it is kept as low as possible compatible with the efficiency of our service. The amount carried to maintenance ships' reserve fund is £9,000, showing an increase of £4,000 compared with the corresponding period of 1894. This increase is really necessary in order to strengthen this fund in view of expenses which we see coming before us. One of our ships—I refer to the "Amber"—will require a new boiler and a general overhaul, which will be expensive. As I have already mentioned, we have made a profit from the hire of our ships during the half-year, and we think the maintenance ships' fund should have the benefit of any profit which may be made in that way. You will observe in the accounts that this profit is credited to the maintenance ships' fund.

The net result of the half-year's work is that, after providing the usual amount for interest on debentures, Debenture stock, and Preference shares, we are able to recommend the usual final dividend of 1¼ per cent. and a bonus of 1½ per cent., making, with the interim dividends already paid, a total distribution of 6½ per cent. for the year ended March 31, 1895, and to carry the sum of £100,000 to the general reserve fund, against £110,000 in 1894. We have also, in pursuance of an arrangement arrived at, and approved by the shareholders some time back, applied a further sum of £50,666 from the reserve fund in reduction of the cost of the Aden-Bombay No. 3 cable and other expenditure chargeable to capital. The total amount applied from the reserve fund now amounts to £1,451,718, and our capital account,

Digitized by Google

with the exception of some additions to buildings, practically remains at the same figure as it has done for many years past—in other words, a little over £6,000,000.

Now, gentlemen, although our general reserve fund is a very substantial sum, and the securities are higher in value than they were when they were made, yet the sum falls very short of what we consider it should stand at, having regard to the number and age of our cables. It has been urged by speakers at some of our recent meetings that we should raise money to provide for capital expenditure, and thus have a large sum available for dividend purposes. This, however, has not been our policy, which has been to keep down the capital account, to provide adequate reserve, and at the same time to pay a good—I think I might say handsome—dividend to our shareholders. This policy has been approved at every meeting at which it has been propounded—approved of by the great body of our shareholders, and I see no reason to expect that it will be altered. I do not think I have anything to add to the remarks which I have now made. Your property is in a very prosperous condition. I observe from a return I have here that the market value of the Eastern Telegraph Company's Ordinary stock, amounting to £4,000,000, is £6,700,000; and taking the whole of our shares—Ordinary and Preference—our debentures, and Debenture stock, their nominal value is £6,099,690, whereas it stands in the market at £9,719,439, an appreciation of 59 per cent. Your Company is in a flourishing condition, the management is both efficient and economical, our traffics are improving, and our relations with the Colonies and foreign Powers are, thanks to our Chairman's tact and energy, on a most satisfactory footing. I therefore think we have a right to expect from you, if not a unanimous, I hope, certainly, a general approval of our report (hear, hear). I now beg to move the motion, but before sitting down I shall be very glad to answer any questions. The resolution is as follows:—

"That the printed report and accounts of the Directors to March 31, 1895, submitted to this meeting, be and the same are hereby received and adopted. That a dividend on the Preference shares of the Company to June 30, 1895, at the rate of 6 per cent. per annum, be paid, less income tax; and that, in accordance with the Directors' recommendation, a dividend be and is now declared of 2s. 6d. per share, with a bonus of 3s. per share, both free of income tax, on the Ordinary shares of the Company, making, with previous payments by way of dividend on account, a total payment of 6½ per cent. on those shares for the year ended March 31, 1895."

Mr. GEORGE GARDEN NICOL: I beg to second that.

The CHAIRMAN: The motion has been proposed by myself and seconded by Mr. Nicol, but before putting it I will inquire whether any gentleman desires to address the meeting.

Mr. GOODSALL: I should like to ask where the 300 miles of new cable has been laid in the 1870 Aden-Bombay cable. Will you let the Managing Director point out on the chart or map where it is?

The MANAGING DIRECTOR (Mr. J. Denison Pender): At the Bombay end.

The CHAIRMAN: The 300 miles has been laid in the section between Bombay and Aden.

Mr. BAYNES: The accounts and the report are eminently satisfactory, not only to the Board but to the shareholders also. Still, notwithstanding this fact, which we have to congratulate ourselves upon, our dividend remains very stationary, and half-year after half-year we carry very large sums to the reserve. In addition to that a considerable portion of the revenue is diverted to duplicating and triplicating the cables and to laying new cables. All these things ought to conduce to the payment of a somewhat larger dividend than the shareholders have been receiving for some length of time. In the early part of the career of this Company the prospect was held out of our receiving dividends of 10 or 15 per cent. That we none of us now expect, because circumstances have arisen which it was impossible for the Directors to foresee. Notwithstanding that, the Company has gone on prospering very much indeed, and we, as Ordinary shareholders, having borne the brunt of the battle, have a right to expect some little increase of dividend. Ours is a very strong and rich Company. I have mentioned this subject before, and on the last occasion Sir John Pender said that the time might arise, and probably would, when the dividend might be increased. The noble lord in the chair, however, does not take that view. I think we are entitled to some consideration, remembering all the circumstances, and the prosperous state of the Company.

The CHAIRMAN: In answer to Mr. Goodsall, I have to say that the 300 miles of cable referred to have been laid in different portions of the Aden-Bombay section, but the repairs have been made on the Bombay side. With respect to the remarks of Mr. Baynes, I can only repeat what was said at the last meeting—by our Chairman, I think. He said he hoped, as soon as the reserve fund was sufficiently large, to be able to give something more to the Ordinary shareholders, and that he would be only too glad to do so when he could. I am sorry to say that the reserve fund is not nearly large enough. We have an immense system—a great number of cables, some of which are very old; and although I am glad to say that age has not injured them so much as we at one time expected, yet our reserve fund is not nearly large enough at present. We are, as you know, adding a substantial sum to it every year, and I am sure that no one could be more anxious than your Chairman to pay a larger dividend than the present one. I only hope that we may live to see that. Well, gentlemen, the motion has been proposed and seconded, and those who are in favour of it will please to signify the same in the usual manner. To the contrary. Carried unanimously. That constitutes the business of the meeting.

Mr. BAYNES: I desire to move a vote of thanks to our Chairman, which I do most heartily, and also to the Board and the staff. I think that they have managed this Company exceptionally well. They have taken care of the interests of the shareholders, and I trust they will continue to do so, and I have very little doubt they will. We do not see our Chairman among us to-day; but he is on election business, and I trust he will return to town again successful as a member of Parliament. It will be very satisfactory to us if that should be so.

Mr. H. P. BURGESS: I have very much pleasure in seconding the resolution, and in endorsing every word which the last speaker has said. Although our Chairman is absent he is not forgotten, and I hope Sir John will be returned with a splendid majority. I think we are very much indebted to him for the manner in which this Company has been conducted so prosperously. I therefore beg to endorse every word that my friend has said in proposing that our best thanks be given to the noble Marquis in the Chair, the Directors, and the staff, who work so ably and so well.

The motion was carried unanimously.

The CHAIRMAN: I beg to thank you on the part of my colleagues and myself, and also on the part of Sir John Pender. I am sure that if he is not here in body he is in spirit, and will be extremely gratified when he sees the account of this meeting and the most cordial manner in which his name has been received.

The proceedings then terminated.

Anglo-American Telegraph Company (Limited).

The ordinary general half-yearly meeting of this Company was held on Friday at Winchester House, the Marquis of Tweeddale (Chairman) presiding.

The SECRETARY (Mr. T. H. Wells) read the notice calling the meeting, and the minutes of the previous half-yearly meeting.

The CHAIRMAN said: Gentlemen, I have now to ask your approval of the report, which has been in your hands for some days, and which, I presume, you will take as read. For three half years and more I have had, when addressing you, to deplore a falling off in our receipts. In July of last year the loss was £16,791, and in January last it amounted to £6,948; but on this occasion I am, happily, able to report to you an increase of £9,382. This, though not a very large addition to our gross income, is a step in the right direction, and an indication, it seems to me, of a return of confidence in business circles which will certainly lead to a greater increase in future. This hope is confirmed by the receipts of the current month, which show a larger increase than we have had during any month of this year. It is somewhat disappointing that the whole of the half-year's increase is not available for dividend. This is in consequence of the ship "Minia" not having earned as much as she did at this time last year. The decrease in the earnings of the ship amounts to £2,550, which, together with the fact that we brought forward a smaller sum into this account by £358, reduces the increase of £9,382, which would otherwise have been available for division, to £6,658. On the other hand, the expenses show one or two satisfactory features. There is a decrease of £1,342 under the head of repairs to cables, but against this has to be set an increase of £1,009, made up of several not very important items. On balance there is therefore a decrease in the expenses of £333. This decrease, however, compares with a considerable decrease at this time last year, so I think it must be regarded as satisfactory. The renewal fund is creeping up, and now amounts to £609,148; but, taking the middle price to-day of the securities in which part of the fund is invested, it will be found that they represent an increased value of no less than £79,000, thereby raising the amount at which the fund may be said to stand to £688,148. Of course, this is much too small a sum for the purpose of the reserve fund, and it will be some time longer before we shall be able to do what we used to do—namely, devote merely the interest obtained from the fund to increasing it. I next come to the important matter of the condition of our cables, and I am glad to say that all our principal cables are in first-rate working order. The new cable is as good, if not better than it was expected to be in point of power of transmission, and the 1873 and 1874 cables, although old—one being 21 and the other 22 years old—are in excellent electrical condition. The same may be said of the 1880 cable. There are two cables interrupted at the present moment: the Duxbury and the Newfoundland-Cape Breton cables, and also, of course, the Brest-St. Pierre cable. Our repairing ship is occupied now in putting the Duxbury and the Newfoundland-Cape Breton cables in good order, and this will take some time, so I am afraid we shall not be able to devote any time to repairing the Brest-St. Pierre cable just yet. The net result of the half-year's working, as you know, is that we are able to pay a dividend of 21s. per cent. in place of 19s. paid for the corresponding half-year in 1894. It is only a slight increase, but still it is in the right direction, and as we have a very large capital it is not so much as otherwise it would be. We have had a good many lean years, and I think we are entitled to look forward to something better in the future. If this hope is realised I shall be able when I meet you six months hence to present a better statement of accounts than we have to-day. I had almost forgotten to refer to the French case, which is still *sub judice*. I think you are aware that we took the opinion of eminent counsel as to the wisdom of appealing from the decision already given in the Court of Appeal. We were advised that there was a reasonable prospect of a successful issue to an appeal, and therefore we have taken the necessary steps to do so. We understand that there is little probability of the case being taken before the Long Vacation, and I do not know whether it will be taken at an early date afterwards or not. If it is we shall be able to give you an account of what has taken place at our next meeting. Gentlemen, with these remarks, which, I think, deal with almost every interesting point connected with the operations of the Company during the past half-year, I beg to move the following resolution:—

"That the report of the Directors and the accompanying statement of accounts, to the 30th of June, 1895, submitted to this meeting, be and the same are hereby received and adopted."

Mr. FRANCIS A. BEVAN (Deputy-Chairman) seconded the resolution.

Digitized by Google

Mr. MICHAEL DAVIES said he should like some further explanation of the law proceedings which had been going on so long. Was it not the fact that the decision already given was in favour the Company?

Mr. HARDY inquired if it were necessary to keep so many cables at work as they were doing?

The CHAIRMAN, in reply, said: With regard to the last question, I may say that in order to earn our share of the pool receipts we must have three cables at work. Considering the age of the four cables, excepting the one we recently laid, it would be dangerous to rely on three of them being in working order for a great length of time, and I think it is only common prudence that we should have one more than the three that are absolutely necessary to secure our share of the pool receipts. Any falling off in our share of the pool receipts would have a serious effect on the dividends we pay, which are small enough already. With regard to the question asked by Mr. Davies, I may say that the judgment already given was in favour of our Company, but not altogether. There was some modification. The most important part of the judgment was that it limited the period during which the Company might claim damages to 3½ years, instead of the entire period since December 31st, 1886. Whether our appeal will lead to any substantial result in the shape of our getting damages is a matter for the future, and one on which it is impossible for us to express any opinion now.

The resolution was then carried unanimously.

On the motion of Mr. JOHN NEWTON a vote of thanks was accorded to the Chairman and the Board of Directors, and the meeting then terminated.

Direct United States Cable Company (Limited).

The thirty-sixth ordinary general meeting of this Company was held at Winchester House, Old Broad-street, on Tuesday. Sir John Pender, G.C.M.G., M.P., presided.

The SECRETARY (Mr. T. Finnis) having read the notice convening the meeting and the minutes of the last ordinary general meeting, the report of the Directors was taken as read.

The CHAIRMAN: Gentlemen—As usual, I will go over some heads of the report, so as to give you such information as I think it is desirable that you should have. The revenue for the half-year to June 30th, after deducting outpayments, amounted in round figures to £37,653, and the working and other expenses, including income tax, but exclusive of the cost of cable repairs, absorbed £18,909, leaving a balance of £18,744 as the net profit of the half-year, making, with £1,808 brought forward from the previous half-year, a total of £20,552, which has been appropriated as follows: Interim dividend of 2s. per share for the quarter to March 31st last, £6,071; final dividend of 2s. per share, now proposed, for quarter to June 30th, £6,071; transferred to reserve fund account, £7,000; balance proposed to be carried forward, £1,410. The revenue, as compared with that in the corresponding period of last year, shows an increase of £2,810, and it is satisfactory to note that the traffic generally is showing a tendency to further improvement after the long-continued depression. The expenses in London, as shown by Abstract "A" in the accounts, remain about the same as in the corresponding period; the items altogether absorb an additional £44. The expenses at stations, as detailed in Abstract "B," show as follows: Increases of £174 in salaries and wages, and £43 in printing and stationery. On the other hand, there are reductions of £51 in maintenance of instruments, £22 in rates and taxes, and £67 in agencies. On the whole, the stations' expenditure shows an increase of £76. In the remaining items of expenditure there is a reduction of £158 in Directors' remuneration, and an increase of £150 in use of patents, due to the automatic transmitter. In the aggregate, the expenses and other payments come within £159 of the same amount as in 1894. The cost of cable repairs has been £1,730, and this has been charged, as usual, to the reserve fund account. At the same time this account has been debited with £673. 14s. 8d. in respect of the cost of old buildings, which have been pulled down to make way for the new permanent buildings now in occupation at Ballinskelligs. On the other hand this account has been increased as follows: By interest on investments, £1,429; by profit on sale of securities, £1,139; transfer from revenue, £7,000; making a net increase of this reserve fund account for the half-year of £10,165, and bringing up the total to £298,369. 18s. 10d. The investments have been increased during the past half-year by £12,331, and considerable further appreciation has taken place in the market value of the securities as a whole, which are to-day worth about £51,000 more than the figure of cost at which they stand in the balance-sheet. Now, gentlemen, that is a very satisfactory account. There is just one dark spot on it, but I hope that with the better times which are coming round we may be able to pay you a better dividend. The United States have passed through a state of depression which, I am told, has not been exceeded since they became a united Government. Looking to a better state in the future, I hope that that dark spot in our position will be obliterated. I call it a dark spot, and I admit freely to you that the dividend we are paying does not contrast well with the old-fashioned 5 per cent. we paid you for so many years; but I repeat what I said at the last meeting—that there are more cables in the Atlantic at present than are required for the work that has to be done. Taking that into account, together with the bad times, the result to you is that you get a dividend of 2 per cent. instead of 5 per cent. I cannot say how soon we shall come back to a better state of things, but judging from the improvement that has taken place in the present month, in which we have a very satisfactory increase, and the increase upon the past half-year was £2,800, we are going the right road at present. I hope we shall continue on the right road until I am able to declare a better dividend than we have to offer you to-day. But it will be satisfactory to you to know that what I have stated shows that the concern is in a very sound condition. I must, however, also remind you that our cable is reaching a period when we have to look carefully after it. Cables, like old people, require a good deal of attention, and we are watching the cable with considerable interest; but there is one satisfactory point in connection with it—that during the times when we have made repairs we have introduced a good deal of new cable into it, and therefore our present cable is not quite so old as it looks, or as we may be told that it is. I am therefore hopeful that for many years yet to come we shall be able to see that our cable is a fairly dividend-earning system. The only other point I have to mention to you to-day—and I shall only say a few words about it—is that the suit in France still goes on, and when it will end I cannot say. At all events, it pleases the French solicitors to keep it going, and as they promise some good results if we get the thing our own way, we cannot very well object. This business, I may remind you, is carried on entirely by the Anglo-American Company. I spoke at considerable length last half-year, and really beyond what I have just now said to you I have very little to comment on; but to leave a good taste in your mouth I may say that your Company is in a very satisfactory position. After a long period of depression I think we have turned the corner, and as you are going upward now I hope that movement will be greatly beneficial to all concerned. I thank you for your attention, and I now beg to move—

"*That the report of the Directors, dated July 9, 1895, together with the statement of accounts to June 30, 1895, annexed thereto, be, and the same are hereby received and adopted, and that a final dividend be now declared of 2s. per share, free of income tax, making, with the interim dividends already paid, a total dividend of 2 per cent. for the year ended June 30, 1895.*"

Mr. E. M. UNDERDOWN, Q.C., seconded the motion.

The CHAIRMAN: Before I put the question I will, as usual, invite any one who desires to put a question to do so now, and I shall be pleased to answer him to the best of my ability.

Mr. VARLEY observed that there was no certificate as to the condition of the cable, but he presumed it was in good working order. The Board had realised some of the securities. It was patent to everyone that the price of Consols was very high indeed, and he would like them to pursue that course and realise the profit now shown. If trade improved the price of Consols would not stand at what it was now. There was a statement that they would rise to 110, but they ought to be careful of such statements.

The CHAIRMAN: This point was put to me six months ago. I said then that 105 was a high price, but at the same time I said that money in the market was not worth more than 1 per cent., and that as long as money was at 1 per cent. and people could get more from Consols, Consols might go up. I consulted more than one banker, and I used my own common sense also; and while I thought that 5 per cent. was the price to realise at, if I had done so I should have thrown away 2 per cent., because Consols are worth 107 to-day, and they are therefore approaching to the 10 per cent. spoken of. I do not mean to say that I am right, or that those bankers who advised me are right; but my common sense tells me that as long as people cannot get 1 per cent. in the market for their money, Consols will rather go up than down. When they get to 10 per cent. I think we will say we had better realise the profit on them. Meantime, I think you must leave the matter in my hands to do the best I can for the Company. I have shown you that I was right last time, and I hope that I may be right this time. As to the condition of the main cable, it is working well. We have one cable—a short one, from Rye Beach to Halifax—down, but I expect before very long that it will be again in working order. Meantime our traffic is not suffering in any way by the interruption, as we have the use of an alternative land-line. I think that is all I have to reply to, and I will now put the resolution to the meeting.

The resolution was carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. JAMES PENDER M.P., Mr. Charles E. Günther was re-elected a Director, as was also Admiral of the Fleet the Hon. Sir Henry Keppel, G.C.B., D.C.L., on the motion of the CHAIRMAN, seconded by Mr. UNDERDOWN.

Messrs. Deloitte, Dever, Griffiths and Co., and Messrs. J. and J. Sawyer and Co., were afterwards re-elected auditors of the Company for the ensuing year, at a remuneration of £50 each.

The CHAIRMAN having intimated that that concluded the business of the meeting,

Mr. VARLEY proposed a vote of thanks to the Chairman and the Board.

Mr. JOHN NEWTON seconded the resolution, and congratulated the Chairman on his successful contest in the North. That was the first time that telegraph shareholders had seen Sir John Pender since his success and he was sure they all congratulated him. He also desired to congratulate Mr. James Pender on his success.

The resolution was carried unanimously.

The CHAIRMAN: It is not always wise to introduce politics on an occasion of this kind, because people have differences of opinion. I have had a hard fight for my seat, I can tell you, and I can therefore speak with a little feeling, but I think you will all agree with me in this—that a strong Government is what is required. I do not care whether it is one side or the other, for I think the common sense of the country will always keep a Government right; but if we have a strong Government—a Government that will work and bear in mind closely the best interests of the large mass whom they have to represent, that is the Government to make a prosperous country. I think that ought to satisfy both sides. My own feeling is strong that we are going to have a strong Government now, if numbers testify anything; and I do hope and believe that they will cease to tinker with the constitution of this great country, and do something to ameliorate the condition of the great mass of the people.

The proceedings then terminated.

Electrical Power Storage Company, Limited.

The sixth ordinary general meeting of this Company was held at the Office, 4, Great Winchester-street, London, E.C., yesterday (Thursday), Mr. John Irving Courtenay in the chair.

The SECRETARY (Mr. J. W. Barnard) having read the notice convening the meeting, the report of the Directors was taken as read.

The CHAIRMAN said: I am glad to meet the shareholders again and to be able to say that the Directors recommend the same dividend as last year, viz., 5 per cent. We have also been able to increase the reserve fund by the sum of £2,684. 12s. 11d., so that this account now stands at the satisfactory figure of £12,000. A larger sum than usual has been spent at Millwall in plant and tools, viz., £1,696. 10s. 8d., which includes new boilers, engine, and building extensions. As stated in the report the Directors have reduced the selling prices of the Company's storage batteries. They fully appreciate the exertions of the manager (Mr. Frank King) and his staff, who have, by their unremitting attention to maintaining the high quality of the Company's batteries, and at the same time reducing the cost of manufacture, enabled the Directors to meet the severe competition in this most practical and telling manner. With these brief remarks I now move the adoption of the report and accounts.

Sir DANIEL COOPER, Bart., G.C.M.G.: I have much pleasure in seconding the resolution—

"*That the Director's report and statement of accounts to May 31, 1895, be and are hereby approved and adopted, and that a dividend of 5 per cent. on the paid-up capital be declared payable forthwith.*"

The resolution was carried unanimously.

It was next proposed by the CHAIRMAN, and seconded by Mr. FREDERICK GREEN—

"*That the retiring Director, Mr. James Pender, M.P., be and is hereby re-elected a Director of the Company.*"

This resolution was also carried unanimously, and the auditors, Messrs. Meston and Co., were re-elected.

A vote of thanks to the Chairman brought the proceedings to a close.

The following is the Directors' report for the period to May 31st last:—

The net profit for the year is £3,419. 16s. 9d., which, with a balance of £993. 14s. 2d. from last year's accounts, amounts to £4,413. 10s. 11d., out of which the Directors recommend the payment of a dividend of 5 per cent. on the Ordinary Share Capital, which will absorb £4,223. 13s. 1d., leaving £184. 17s. 10d. to be carried forward. Provision has been made for the effective maintenance of buildings, plant, tools, &c., at a cost of £2,373. 7s. 3d. The reserve fund for diminution in value of assets has been increased by the sum of £2,684. 12s. 11d. out of the profits of the year's working, and now amounts to £12,000. The Directors are pleased to report that the Company's batteries still maintain the leading position which they have for some years occupied. The Company's staff has devoted considerable attention to reducing the cost of manufacture, and the Directors have, in consequence, further reduced the selling prices.

Globe Telegraph and Trust Company (Limited).

The twenty-second ordinary general meeting of this Company was held on Friday, July 26, at Winchester House, Old Broad-street, E.C., under the presidency of the Marquis of Tweeddale.

The SECRETARY (Mr. Sidney Collett) read the notice convening the meeting.

The CHAIRMAN, in moving the adoption of the report, said: The receipts for the year ended July 18th inst., after paying all expenses, amounted to £179,465, as against £195,076 in the previous year, or a decrease of £5,611. This reduction is attributable to three causes—namely, the smaller dividends we have received from the Anglo-American Company for the first two quarters of the current financial year; smaller returns on our investment in the Direct United States Cable Company, and also the paying off of the Direct Spanish Company's Six per Cent. Debentures. I need hardly say that it will not be easy to replace these debentures with a stock having as high a rate of interest as 6 per cent. However, notwithstanding these losses, we are able to recommend to-day the payment of a dividend on the Ordinary shares of 4½ per cent. for the year under review, as against 4½ per cent. for the previous year. This, you will observe, gentlemen, is a lower figure, but, remembering the state of depression which has been prevailing during the last few years, the dividend we are declaring to-day is, after all, a very fair one, especially when I tell you that if you take the two classes of shares in like quantities they show a return of £5. 1s. 3d. per cent. Now, gentlemen, it has been the practice of our Chairman from year to year to give you the most ample information with respect to the Company that is possible, and I do not propose on this occasion to make any departure in this respect. I will, therefore, give you particulars of the several investments in which the returns have differed from those of last year. The Anglo-American Telegraph Company has paid us £2,547 less than we received from them last year, but the whole of this loss belongs, as I have already mentioned, to the first two quarters of the year under review. The dividends we received from that Company in respect of the third and fourth quarters, I am glad to say, show in both cases increases over the amounts received in the corresponding quarters of 1894, and a further increase is announced in that Company's report, just issued, in respect of the dividend to be paid on August 1st. These increases are due to—what we all like to see—the growth of traffic passing over those lines, resulting, no doubt, from a better state of trade generally, which is noticeable on all hands. You will observe on comparing the statements of page 6 of the report with that of last year, that we have sold £1,120 Anglo-American "B" Preferred Stock and a similar amount of Deferred "A." The reason of this was that we have recently bought, as the report shows, some more Submarine Cables Trust certificates. These certificates, as probably most of you know, contain a proportion of Eastern and Eastern Extension Companies' shares and Anglo-American Company's stock, but as it was deemed by the Directors inadvisable to increase our interest in the Anglo-American Company, it was decided to sell a proportion of the Anglo-American stock equal to the amount of that Company's stock which we may be said to have acquired in purchasing the Submarine Cables Trust certificates. You understand that we considered it, on the whole, a better investment—these Submarine Cables Trust certificates. We preferred having our share of Anglo-American stock in Submarine Cables Trust certificates rather than in its previous form. We consider that we purchased the Submarine Cables Trust certificates at a very moderate price, which I shall mention afterwards, when I come to that investment. The Cuba Submarine Telegraph Company, as you will observe, gentlemen, is a new investment; the Company has been for years a quiet and prosperous one. For several years past they have been paying very good and steady dividends, and while you know there is at present an insurrection in the island of Cuba, still for the moment this is acting as a feeder to those cables, and if their usual dividend is maintained, we shall receive over 6 per cent. on our investment in that undertaking. The Direct United States Cable Company has paid us £1,989 less than the amount we received from them last year; but I am glad to be able to tell you that there are distinct signs of increased traffic over the lines of this Company, and if this continues we, of course, shall share in the benefits of that increase. Since the last meeting a further sum of £38,592, resulting from the paying-off of the Direct Spanish Company's Six per Cent. Debentures, has been invested as follows: 520 Ordinary shares of the Direct Spanish Company, 102 certificates in the Submarine Cables Trust, 1,135 shares in the Western Union Company, 400 shares in the Cuba Submarine Telegraph Company. I need scarcely say that your Directors have had considerable difficulty in re-investing this money, which amounted in all to over £62,000, and on which we were receiving 6 per cent., because, while our first consideration must ever be to invest in such securities as will preserve our capital intact, and as far as possible avoid the risk of depreciation, still, seeing that we have to pay 6 per cent. to our Preference shareholders, which represent half of our capital, the question of the return on the money we invest has always to be very seriously considered. You will remember that at our last meeting it was mentioned that some of this money had been temporarily invested in Egyptian Government Three per Cent. Guaranteed Loan and Two and Three-quarters per Cent. Consols; the greater part of this, I am glad to say, has now been permanently placed. We sold the Egyptian stock at a much higher figure than we bought it at, and therefore a considerable profit on this temporary investment has been the result. The Consols also stand at a very much higher figure to-day than we bought them at, so that there will be a further profit on these when we find it desirable to dispose of this investment. As I have already mentioned, we have increased our holding in the Submarine Cables Trust; but there is one point under this heading which needs a little explanation. If you compare the figure given in the last column of the statement on page 6, showing the cost per £100 certificate, with that given in last year's report, you will see that it is slightly higher; but this difference is, I may say, more apparent than real, in this way—that the nominal loss on the sale of the Anglo-American stocks referred to has been added to the cost price of the Submarine Cables Trust certificates recently acquired. However, as your Directors, in purchasing these certificates, took advantage of the low prices which recently prevailed, the cost price of this stock is very much below the present market value—on the whole a very satisfactory transaction. In regard to the West African Telegraph Company, you will remember that, on the last occasion of our meeting, Sir John Pender explained to you the precautions that had been taken with a view to preventing the heavy expense connected with the frequent interruptions to this Company's cable, and he said that he hoped when he met you again he would be able to report some return on our money invested in this Company. That hope, I am glad to say, was not without good foundation, for although we have not as yet actually received any dividend on those shares, still a dividend has been declared of 2s. per share, and is payable to-day. This will give us over £300, and, though small in itself, is, we trust, only the beginning of better things in the future. The returns from the Western and Brazilian Telegraph Company are more encouraging, as we have received £300 more in dividends from them this year than they paid us last year. The returns on our other investments show but little or no change. Many of the companies in which we hold large interests continue to return us very handsome dividends, as you will see from the report in your hands. There is one thing I would like to mention before closing my remarks, and that is the increased confidence in this Company's shares shown by investors. This is illustrated in a most remarkable way by the fact that our Ordinary shares, which stood this time last year at 8¼ to 8½, are now quoted at 10$\frac{1}{16}$ to 10$\frac{5}{16}$, and the Preference shares, which in July, 1894, were 15⅜ to 15⅝, now stand at 17 to 17¼. It will further interest you when I tell you that the market value of the securities we hold has been steadily increasing for the last year or two, and to-day, while the amount of our paid-up capital is £3,602,690, the present market value of our securities is £4,395,395, showing the very handsome surplus balance of over £792,000. That is notwithstanding the fact that the depreciation in our American securities is nearly £500,000, which is included. In spite of that, however, the surplus balance is £792,000. It is just as remarkable that that amount is £429,862 better than this time last year, and I think you will agree with me that this is a very satisfactory statement to be able to make. I have only to refer, in conclusion, to Sir Henry Gooch's resignation. We need not tell you that we regretted the necessity he found himself under to sever himself from our Company, with which he had been connected, as well as his father before him; but he had very few engage-

Digitized by Google

ments in London, and he found it very inconvenient to come up to the meetings. He has therefore resigned his post. There is another matter which, I think, will perhaps interest the shareholders—the question of the payment of our dividends half-yearly instead of quarterly. If any gentleman thinks it right to address the meeting, perhaps he will offer a few remarks on this point. The Chairman then proposed the adoption of the report and accounts.

Lord SACKVILLE A. CECIL seconded the motion.

Mr. MICHAEL DAVIS inquired what the Company gave for the "B" stock of the Anglo-American Company, and what it was sold at.

Mr. JOHN NEWTON remarked that he had been a shareholder in the Company from the commencement, and, as regarded making any change in the periods at which they declared their dividends, he thought the shareholders might take a lesson from the emphatic opinion which has just been pronounced by the country at large in demonstrating the importance of not tinkering with their Constitution. He considered that a great deal of the high price and the market stability of telegraph property was due to the payment of quarterly dividends; and it should be remembered that many claims were made upon them every quarter for taxes and other payments.

Mr. WICKHAM inquired the price paid for the Submarine Cables Trust certificates.

The CHAIRMAN, in reply, stated that it was not possible to say what they paid for their Anglo-American "B" stock separately, for it was purchased before the division of the stocks took place. The Anglo-American stock was formerly one, but the holders were given the option of dividing it into Preferred and Deferred stock. This option was not exercised by the Globe Company, and we have now sold, as I have already stated, a small proportion of Preferred and Deferred.

Mr. DAVIS said that they held about one-third of their capital—namely, £1,115,114—in the stocks of the Anglo-American Company, and he did not think that their holding ought to be so large in that concern.

The CHAIRMAN, continuing, said that they sold £750 Preferred "B" stock in the Anglo-American Company at 81½, and a similar amount of Deferred stock at 7⅞, and £370 of Preferred "B" stock at 81⅝, and £370 of Deferred "A" stock at 7⅞.

Sir John Pender, G.C.M.G., M.P., and the Hon. St. John Brodrick, M.P., were re-elected to their seats at the Board, and Messrs. Deloitte, Dever, Griffiths and Co., and Mr. William Griffith, B.A., were re-elected as auditors.

Mr. NEWTON proposed a cordial vote of thanks to the Chairman and Directors for their successful management of the Company's affairs, which was unanimously carried.

The CHAIRMAN briefly responded, and the proceedings terminated.

Thomas Parker (Limited).

The first annual meeting of the shareholders of this Company was held on Wednesday at the Works, Wednesfield-road, Wolverhampton, under the presidency of Mr. Alderman C. T. Mander.

The CHAIRMAN, in moving the adoption of the report and accounts, said the Company did not commence work until January last, and consequently the balance sheet only represented six months' trading. The Company had developed in a satisfactory manner, and during July it had increased to such an extent that additional hands had to be employed. It was gratifying to them all that the dispute with the Electric Construction Company had been settled, and as the result of long negotiations that Company had paid them £2,000, and had given them the right to use several patents which had not been included in the prospectus of Thomas Parker (Limited). He hoped, therefore, that the public would now take up the remainder of the shares, in order that the works might be extended. They had over £24,000 worth of orders on their books, they were turning out an enormous quantity of work, and there was every prospect of a continuance of good business.

Mr. T. PARKER (the Managing Director), in seconding the motion, said that the invoices for July were of the value of £5,000, and if that standard could be maintained, and he had no doubt it could, shareholders would find the business a profitable one. The present turnover would earn a profit, and a little more capital expenditure would enable the Directors to double the output; in fact, they could obtain any number of orders if they were in a position to execute them.

The resolution was adopted, and the Chairman and Mr. W. Thomas were re-elected Directors, Mr. R. Armistead being appointed a Director in place of Mr. T. Graham, who had resigned. The auditors were re-elected, and the usual vote of thanks to the Chairman terminated the proceedings.

Cuba Submarine Telegraph Company (Limited).

The report of the Directors of this Company for the half-year ended June 30th last, which will be presented at the forty-eighth general meeting, held at the offices, 58, Old Broad-street, London, E.C., on Wednesday, the 7th inst., at 12 o'clock, states that the gross receipts amount to £30,817. 1s. 5d., and the gross expenditure to £6,118. 14s. 8d., leaving a sum of £24,698. 6s. 9d., which, added to the balance brought from the last account, £3,380. 3s. 6d., leaves £28,078. 10s. 3d. to the credit of revenue account.

The insurrection in Cuba, which broke out in February last, and still continues, has caused an abnormal use of the Company's lines, with a corresponding enlargement of receipts. As, however, the business of the island will no doubt suffer from the effects of the war for some time after the restoration of order, it has been thought advisable to place the sum of £13,638. 10s. 5d. to the reserve fund. The sum of £1,500 has been set aside as a further reserve against any loss from the deposits with banks.

The dividend on the Preference shares will absorb £5,000, and leave £9,939. 19s. 10d., out of which the Directors recommend the payment of a dividend on the Ordinary shares at the rate of 8 per cent. per annum, free of income tax, the balance, £3,539. 19s. 10d. being carried forward to the current half-year.

The cables have continued in good order throughout the half-year. The new cable between Batabano and Cienfuegos was taken over from the contractors on March 4th, fulfilling in all respects the requirements of the contract. The balance of the cost has been deducted from the reserve fund.

The position of the Company's suit against the Spanish Government at Madrid remains the same as at the date of the last report.

The report refers to the death of Mr. Thomas Greenwood, and the retirement, owing to advanced age, of Mr. A. F. Low. Mr. Robert Kaye Gray and Mr. A. G. Low have been appointed to the vacancies on the Board. Mr. R. K. Gray seeks re-election at the meeting, as does Mr. John Gane, the auditor.

Liverpool Overhead Railway Company.

The report of the Directors of this Company for the half-year ended June 30th last, to be submitted to the general meeting held at the Law Association Rooms, Cook-street, Liverpool, on Tuesday, the 13th inst., at 3 o'clock, states that the gross revenue receipts for the half-year amount to £28,143. 3s. 1d., and the working expenses to £18,653. 18s. 1d. The number of passengers carried since the opening of the railway is as under:—

	Half-year ending Dec. 31, 1893.	Half-year ending June 30, 1894.	Half-year ending Dec. 31, 1894.	Half-year ending June 30, 1895.
First class	260,221	277,653	362,179	400,260
Second class	1,293,840	1,246,975	2,228,224	2,114,462
Workmen (special return tickets)	921,578	1,336,803	1,050,976	945,338
Total	2,475,639	2,861,437	3,641,379	3,460,060

The contracts for the southern extension have been let, and the works will be commenced without delay. In order to meet the necessary expenditure, the Directors have decided to offer to the shareholders at par, on application, the unissued portion of the Ordinary capital.

From the total receipts of £28,143. 3s. 1d. has to be deducted the interest on Mortgage Debentures, amounting to £2,500, leaving, with the balance brought forward (£1,087. 12s. 5d.), £8,076. 17s. 5d. available for dividend. Out of this balance the Directors recommend dividends at the following rates (less income tax), payable on and after August 17th, viz.: 5 per cent. per annum on Preference shares, taking £2,529. 0s. 9d., and 2½ per cent. per annum on Ordinary shares, taking £4,244. 17s. 9d., leaving £1,302. 18s. 11d. to be carried forward.

NEW COMPANIES, STATUTORY RETURNS, &c.

AUTOMATIC ELECTRIC SIGN COMPANY (LIMITED).—This Company was registered on July 23rd, with a capital of £5,000, in £1 shares, to enter into and carry into effect two agreements made between George F. Kenyon, Frizinghall, Bradford, electrician, and James S. Critchley, Bradford, engineer (for the Company), to acquire, develop, work, and generally deal with any inventions and rights capable of being used in connection with the supply of electricity, and to carry on the business of electricians, suppliers of electricity for the purposes of light, heat, motive power, advertisement signs and like devices, advertising agents, makers of signs and devices, iron and brass founders, mechanical engineers, tool makers, &c. The subscribers, with one share each, are: J. A. Jessop, W. Craven, G. F. Kenyon (electrical engineer), T. Newboult, E. Niven (electrical engineer), C. Wilson and H. Jackson. The first Directors are: J. A. Jessop, W. Craven, and G. F. Kenyon (managing).

I.E.S. ACCUMULATOR COMPANY (LIMITED).—This Company was registered on July 26th, with a capital of £100,000, in £1 shares, to carry on the business of manufacturers of and dealers in electric storage batteries and electrical engineers in all its branches, electricians, mechanical engineers, manufacturers, sellers and dealers of and in electricity, motive power, light, electrical apparatus and appliances; to generate, produce, store, accumulate, and distribute electricity, electromotive force, or other similar agency, for the purpose of lighting omnibuses, tramcars, cabs, and other vehicles, buildings, manufactories, mines, ships, lighthouses, railways, &c.; and to acquire the right to use, manufacture, or put up telephones, telegraphs, electric bells, phonographs, &c. The subscribers, with one share each, are: J. L. Higgs, Edward Mann, electrical engineer; Percy Greville, electrician; C. E. Masterman, J. B. Evans, electrical engineer; J. Lloyd, and W. J. Griffiths.

HUBERT GRENFELL (LIMITED).—The statutory return to June 4th has been filed. The nominal capital is £12,500, in 10,000 Ordinary and 2,500 Preference shares of £1 each, and of these 8,250 Ordinary shares have been issued as fully paid. In addition, 895 Preference shares have been paid for in full.

JOHANNESBURG LIGHTING COMPANY (LIMITED) (IN LIQUIDATION).—The annual return to June 14th has been filed. The nominal capital of £127,132 is divided into 77,132 Ordinary and 50,000 Preference shares of £1 each. 77,125 Ordinary shares have been issued as fully paid, and the full amount has been paid on the remaining Ordinary shares.

Digitized by Google

JONES BROTHERS AND COMPANY, BIRMINGHAM (LIMITED).—The statutory return to September 19, 1894, was filed on June 1st. The capital is £2,000, in 1,000 Preference and 1,000 Ordinary shares of £1 each. 800 Ordinary and 300 Preference have been taken up, and considered as fully paid.

LLANDUDNO ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return to July 6, 1894, has only just been filed. The nominal capital is £15,000, in £10 shares. Only 14 shares have been taken up, and the full amount has been paid on these. As the Llandudno Improvement Commissioners have passed a resolution to carry out the electric lighting of the district themselves, it is proposed to call a meeting to consider the advisability of winding up the Company.

PHONOPORE COMPANY (LIMITED).—The annual return to June 27th has been filed. The nominal capital is £150,000, in 100,000 Ordinary and 50,000 Preference shares, all of £1, and of these 90,000 Ordinary and 28,343 Preference shares have been taken up. 69,025 of the former and 10,380 of the latter have been issued as fully paid. The full amount has been called on the remaining 20,975 Ordinary and 17,963 Preference shares.

RIVER PLATE ELECTRICITY COMPANY (LIMITED).—The annual return to June 13th has been filed. The nominal capital is £500,000, divided into 49,900 Ordinary shares of £10 each, and 1,000 Founders' shares of £1 each. 13,557 of the former and 892 of the latter have been taken up, and 2,400 of the Ordinary have been issued as fully paid. The full amount in each case has been called on the remaining shares.

TELEGRAPH MANUFACTURING COMPANY (LIMITED).—The annual return to June 21st has been filed. The nominal capital is £50,000 in £10 shares, and of these 3,310 have been taken up. 646 have been issued as fully paid, and the full amount has been paid on the remainder.

UNITED ELECTRIC SEWAGE AND CHEMICAL SYNDICATE (LIMITED).—This Company is extinct.

UNITED ELECTRIC TRAMWAYS (LIMITED).—The annual return to December 31, 1894, has only just been filed. The nominal capital is £30,000, in 6,000 £5 shares, of which 3,007 have been allotted. Of these, 3,000 were issued as fully paid, and the full amount has been paid on the remainder.

VAUGHAN AND BROWN (LIMITED).—The statutory return to June 22nd has been filed. The nominal capital is £40,000, in 4,000 Preference and 4,000 Ordinary shares of £5 each. 2,600 of the former and 2,620 of the latter have been taken up, and 2,000 of each class have been issued as fully paid. The full amount has been called on the remaining 600 Preference and 620 Ordinary shares.

WEST COAST OF AMERICA TELEGRAPH COMPANY (LIMITED).—The annual return to June 25th has been filed. The whole nominal capital of £300,000, in £10 shares, has been paid up.

CITY NOTES.

BRISTOL TRAMWAYS AND CARRIAGE COMPANY (LIMITED).—The report of the Directors for the half-year to June 30 states that the gross receipts amounted to £42,820. 17s. 10d., and the expenses to £33,177. 7s. 10d., leaving a balance of £9,643. 10s. The report also states that the construction of the line between the City and Kingswood, which is to be worked by electricity, and the conversion of the St. George's depôt into a generating station, are approaching completion; and it is anticipated that this portion of the line will be opened for traffic within a few weeks. This may fairly be claimed as one of the smartest bits of work in the way of rapid tramway laying ever effected in this country. The extent of the reconstruction is two miles, but, with the large portion of double line, the actual run of single line laid has been three miles, and this work has been done in six weeks, or at the rate of a mile a fortnight. The Company originally intended to adapt the old line with its T rails and chairs, but about two months ago decided to lay down a new line with girder rails and a heavier form of construction, uniform with the new section in course of construction from St. George to Kingswood. With the assistance of Mr. J. C. Robinson, C.E., upon whose report the Directors had already acted in connection with the electrical scheme, and who was in cordial co-operation with Mr. Challenger, the traffic manager, the whole of the work was completed to time. As an earnest of the Directors' appreciation of the smartness displayed, they voted £100 for distribution amongst those engaged in the work.

CHARING CROSS AND STRAND ELECTRICITY SUPPLY CORPORATION (LIMITED).—The Directors of this Company have declared an interim dividend for the half-year ended 30th June last, at the rate of Four per Cent. per annum on the Ordinary shares, amounting to £150,000, and have carried forward £2,870 to next account. The dividend will be paid on and after August 12th.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended July 28, 1895, were £827, against £858 in the corresponding week of 1894, a decrease of £31. The total receipts for half-year amount to £3,421, against £3,458 for the corresponding period of 1894, a decrease of £37.

ELECTRICAL BANKING ENTERPRISE.—A bank for financing electrical undertakings has, it is stated, been constituted at Zurich, Switzerland. The share capital is to be £1,200,000, of which 25 per cent. is to be paid up, and the Directors are authorised to issue bonds to the amount of double the paid-up capital.

GAS LIGHT AND COKE COMPANY.—The report of the Directors of this Company, which will be presented to the meeting of shareholders to-day (Friday), refers to a large increase in the quantity of gas sold during the six months to June 30th, which is stated to be equal to 6⅝ per cent. excess over the corresponding half-year of 1894. A reference is made to a considerable increase in the number of consumers of gas supplied on the automatic meter system, but no reference is made to the competition of the electric light.

GULCHER COMPANY (in Liquidation).—As announced in our last issue, an extraordinary general meeting was held at 73, Lombard-street, London, E.C., on Monday last, to receive the liquidator's statement of accounts. Our representative was informed that the meeting was private.

W. T. HENLEY'S TELEGRAPH WORKS COMPANY (LIMITED).—The first batch of letters of allotment for the new issue of Ordinary shares in this Company has been posted. The entire issue was, it is stated, taken up by the shareholders of the Company.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 28th inst. amounted to £1,197. The amount for the corresponding week last year was £933. Increase £264.

NATIONAL TELEPHONE COMPANY (LIMITED).—The Right Hon. Lord Harris, G.C.S.I., G.C.I.E., has been elected a Director and Vice-President of this Company, to fill the vacancy caused by the resignation of Lord Balfour of Burleigh; and Sir Henry George Calcraft, K.C.B., has been elected a Director, to fill the vacancy caused by the resignation of Colonel R. Raynsford Jackson.

OTIS STEEL COMPANY (LIMITED).—Meetings of the First Mortgage Debenture-holders, Preference shareholders, and Ordinary shareholders will be held at 2:0, 2:45, and 3:15 p.m. respectively on August 14th, at Winchester House, London, E.C., to consider a scheme of arrangement proposed to be made between the holders of such debentures and the Company.

RAND CENTRAL ELECTRIC WORKS (LIMITED).—The statutory general meeting of this Company was held on Wednesday at Winchester House, Old Broad-street, E.C. Sir Charles Rivers Wilson, who presided, said that the Board had every expectation that the hopes held out when the Company was formed would be fully realised. The contractors had arranged to complete their portion of the work within 18 months from May 3rd last, and they would hand over all the appliances not later than November 3, 1896. The London offices of this Company have been removed to 120, Bishopsgate-street Within, E.C.

REDUCTION OF CAPITAL.—Notice is given that by an order of the Chancery Division of the High Court of Justice, dated June 29, 1895, the reduction of the capital of the British Electro-Chemical Agency (Limited), from £75,000 to £50,000, was confirmed. The minute showing the several particulars required by the statutes was registered by the Registrar of Joint Stock Companies on the 23rd ult.

SANITAS COMPANY (LIMITED).—The Directors of the Sanitas Company, makers of the well-known "Sanitas" powders, fluids, soaps, &c., have declared an interim dividend at the rate of 10 per cent. per annum for the six months ended June 30th last, free of income-tax, payable September 1st next.

ST. JAMES'S AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED).—Warrants for the interim dividends on the Preference and Ordinary shares of this Company for the half-year ended June 30th last have been posted.

STOCK EXCHANGE NOTICES.—Application has been made to the Stock Exchange Committee to allow 25,000 shares (Nos. 1 to 25,000) of the Amazon Telegraph Company (Limited) to be quoted in the official list.

TORONTO RAILWAY COMPANY.—This Company, which operates by electricity the only street railways in the City of Toronto (Canada), has this week, through Messrs. Coates, Son and Co., of 99, Gresham-street, London, E.C., invited applications for £323,000 sterling Four and a-Half per Cent. First Mortgage Bonds of £100 each, on which interest is payable half-yearly. The price of issue is £108 per bond, payable £5 on application, £10 on allotment, and £93 on August 31st inst. The Company was incorporated in 1892, and has the exclusive privilege of working street railways in Toronto for a term of 30 years from September 1, 1891, and is now operating 85 miles of electric railways in that city. The bonds are stated to be secured by a mortgage trust deed, and are a first charge on the undertaking after working expenses, annual payment of the Municipal Authorities under agreement, and certain payments of debentures issued by the original Company, and which are being redeemed, have been made. The gross earnings for 1894 amounted to $958,371. The Company's paid-up share capital is $6,000,000, and the assets have been valued at $9,562,318. The list of applications closes this day (Friday) at 4 p.m.

WATERLOO AND CITY RAILWAY COMPANY.—The report of the Directors of this Company, to be submitted at the third half-yearly meeting, to be held at Waterloo Station, London, S.E., on Thursday next, at 2:30 p.m., states that the Directors submit the following statement of accounts: The expenditure for the half-year ended June 30th amounted to £48,982. 3s. 6d., and that the probable further outlay within the current half-year rendered it necessary to make a call of £2 per share upon the 54,000 shares of the Company, payable on July 1st. The severe weather during the early part of the year caused a complete stoppage of the works for several weeks, but since that time satisfactory progress has been made. The tunnels have been completed under the river, and are being extended rapidly towards the City as well as in the direction of Waterloo. Negotiations are in progress for the terminal stations, the contracts for which will shortly be let, and the works commenced before the end of the year.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended July 26th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,109.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 899. [No. 15. Vol. XXXV.] FRIDAY, AUGUST 9, 1895. PRICE SIXPENCE.

NOTES.

Considerable interest of far-reaching importance attaches to the judgment delivered by Mr. Justice Stirling, last Saturday, in the action brought by the Board of Works for the Wandsworth District against the County of London and Brush Provincial Electric Lighting Company. The kernel of the interest lies in the judgment, as to what constitutes a "street box"; or rather, as to what power the Board of Trade possesses to sanction any particular excavation under a public thoroughfare, as constituting a street box "within the meaning of the Act." The evidence brought forward by the parties to this action will be found in our last issue; and this week, in our "Legal Intelligence," we give the particulars of Mr. Justice Stirling's decision. To our mind, one of the chief merits and beauties of this decision is to be found in the opinion which his lordship expressed "that the question of size (of admissible street boxes) was entirely within the province of the Board of Trade." A street box, on the one hand, is not necessarily to be cribbed, cabined and confined within the dimensions which it had when the Act was passed; nor, on the other hand, is it to know no confining law, and to expand itself, at the sweet will of the contractor, until it might hold a whole central station; but its existence is to depend on the veto of a governing body, whose experience in these matters is amply sufficient, as its judgment is competent, to enable it to hold a fair and even balance between the requirements of electrical practice and the safety of the public.

We reprint this week an interesting and valuable Paper on "Electric Power in Factories and Mills," which was read by Messrs. Crocker, Benedikt and Ormsbee, at the Niagara Falls meeting of the American Institute of Electrical Engineers. The authors embody in their Paper a number of tests of electric motors driving machine tools, under workshop conditions, at the Crocker-Wheeler Electric Company's works at Ampère, N.J. In the main we are in agreement with the authors in believing that in a great many mills and engineering works electric motors might advantageously replace the usual transmission gear. There are cases in practice where the long-continued operation of electric motors has proved this to be so. But we are, as yet, by no means warranted in supposing that in every case, or even in the general majority of cases, these advantages would accrue. In some of the instances cited by the authors, and in other works not mentioned by them, the original transmission plant replaced by electric motors was by no means as economically or suitably arranged as is possible. Where there are many hundreds of feet of steam pipe, and many intermediate lines of belt-driven shafting, almost any change must be for the better. It is only by a comparison of what electric motors can do in competition with the best and most modern arrangements of mill gear that a really useful index of the progressive value of the former can be obtained. We do not make these remarks from lack of faith in electric motors for mills; but because we believe that their true and lasting value can only be determined on some such grounds as these. For the present, each particular case must be worked out on its own particular merits and requirements; and it seems probable that while only a limited percentage of existing works could advantageously be transformed, it would pay to fit up on the electric system a far larger proportion of quite new works. This latter is what the Crocker-Wheeler and the Westinghouse Companies have done with so much advantage already.

There is an impression on the minds of some engineers that one of the chief advantages of the electric system is, as the authors assert, "that the consumption of energy ceases when the tool stops." This is not strictly true; or rather, it is true only in a limited sense; and if the fallacy is not guarded against, a serious error will creep into the estimates. As the authors go on to state: "This stoppage in the case of the busiest tools amounts to at least 25 per cent. of the nominal working hours throughout the year, and with large or special tools, which are not used so steadily, the stoppage is often as high as 50 to 75 per cent." This means that during from 25 to 50 or 75 per cent. of the *working* hours the generating machinery is running round without driving any tools. It will not, therefore, be strictly true that over that period there will be absolutely no energy consumed; for a considerable consumption will be required to overcome the internal and dead friction loads of the generating plant. What is true, however, is that so long as any particular electric motor is not running there will be no electrical losses in it, while the losses in the line will be more than proportionately diminished from their full value.

The distribution of hydraulic power in towns has always possessed more than a single interest for electrical engineers; and in the recent Paper read by Mr. E. B.

Digitized by Google

Ellington before the Institution of Mechanical Engineers, an abstract of which we publish this week, a further interest is contributed. The similarities, on the one hand, and the essential elements of difference, on the other hand, between hydraulic and electric power supply, have taught electrical engineers more than one lesson in central station practice and economy, and have often furnished texts for valuable sermons from the leaders of the profession. The latest phase in the association together of the two branches of engineering is the impartial and careful inquiry, which Mr. Ellington has made, into the practicability of working electric supply systems with power metered from hydraulic mains. Digressing for a moment, we cannot refrain from commenting with amusement upon that solicitude with which the distributors of non-electrical power, whether pneumatic, gaseous or hydraulic, have sought to aid the electrical engineer in his competitive labours, by offering him their wares at his central station door. The situation is not without a humour of its own; though in all seriousness, there is often on both sides a great deal to recommend it. But the working of electric sub-stations from a hydraulic power centre, as discussed by Mr. Ellington, does not appear to offer any substantial advantages over the use of a steam-driven electric central station. Indeed, it appears that where some such combined system has already been tried, viz. at Antwerp, the results have not been satisfactory; and this, though the cost of labour and other conditions appear to be unusually favourable.

To turn to figures, some lessons may be learned from the table which accompanies Mr. Ellington's Paper, and which draws a comparison between the cost of hydraulic power generated at the London Hydraulic Power Supply Company's station, and that of the electric power generated by the Westminster Electric Supply Company. The costs are, respectively, 0·793 penny and 1·383 pence per Board of Trade unit or its equivalent. The difference is large enough to bring credit to the hydraulic, and hope to the electrical engineer; but it is not so great as to warrant the former in expecting to gain profit by supplying power to the latter. Taking the figures as they stand, and leaving the question uncomplicated by other financial considerations, this difference is 0·59 penny per unit. With this margin, the whole of the expenses of hydraulic transmission and conversion into electrical energy, as well as the profit to be made, would have to be covered. Nor is this all, for the condition of load factor under which an electric station works is inferior to that found in the hydraulic station mentioned; and the engines in the former are not, as Mr. Ellington has assumed, worked very closely to full load for the greater part of the time of running. On the contrary, Prof. A. B. W. Kennedy stated in the discussion that even "recently this factor for those engines had been 80 per cent., 70 per cent., and even 55 per cent." That being the case, the margin of 33 per cent. loss, between hydraulic generation and electric generation, which Mr. Ellington has assumed, is not in our opinion sufficient; while the narrow margin of 0·59 penny would probably fall far short of the requirements, even if no profit was to be counted upon.

In our issue this week Mr. W. G. Rhodes describes a neat method of obtaining the general equation to a magnetic field caused by two point poles in air. The equation to the magnetic potential at any point in the field is considered, from which the differential equation to the equipotential surface is obtained. As the lines of force are the orthogonal trajectories to the successive equipotentials, or in other words cut these normally, the general differential equation to these trajectories can be derived from the equation to the equipotential surface; and therefrom, by integration, the required equation to the line of force is obtained. As compared with the usual equation for equal poles, in which the sum of the cosines is equated to zero, the result in this general equation is to substitute for unity the coefficient k, equal to the ratio of the pole strengths, as the coefficient of the cosine of the angle at the stronger pole. Mr. Rhodes's method of arriving at this simple result is neat, and should be of interest to elementary students. A general Cartesian equation is, of course, readily obtainable from this result, as Mr. Rhodes has shown.

A correspondent draws attention in our columns this week to the need for increased rigorousness in the reproduction of standard screw threads and other standardised pieces of mechanism. Mr. Elphinstone's long and extensive experience in the use of such mechanism gives considerable weight to his statement that "B.A. screws bought to-day from any good makers are not necessarily of the same dimensions as those supplied on a similar order, by the same maker, a month or so ago, and the difference is often fairly large." Interchangeability, and the convenience of being sure that screws bought at one time will fit nuts bought at another time, are not to be assured even by the most careful and scientific specification of standards, unless there follows the utmost possible care to see that these standards are faithfully reproduced.

Cable Interruptions.—There is again no interruption to report in submarine telegraphic communication.

Islington.—A local journalist refers to the chimney of the new Islington electric supply station as "the big chimney which is to carry off the fumes of generation."

Iron and Steel Institute.—The autumn meeting of this Institute will be held at Birmingham on Tuesday, Wednesday, Thursday and Friday, the 20th, 21st, 22nd and 23rd of August.

The Telephone in Japan.—At the end of the commercial year 1893-94 there were at Tokio six telephonic exchanges; at Yokohama, two; at Osaka, three; at Kobe, two; there were in all 2,672 subscribers. The cost is about £7 per subscriber.

Deaths by Lightning.—At Boxford on Friday last a farm labourer was killed by lightning while taking shelter under an elm tree.——During a thunderstorm which passed over the district of Thurso on Monday last a man employed on a farm was struck by lightning and killed instantly.

Lighthouse Communication.—The temporary telegraphic communication recently established with the Fastnet Lighthouse is working very satisfactorily, and is being rapidly made permanent. This particular installation is exciting great interest, as Fastnet, which is nine miles from Crookhaven, receives unbroken the Atlantic storms.

Liverpool Electric Supply.—The Liverpool Corporation has now definitely decided upon the purchase of the Liverpool Electric Supply Company's undertaking for the sum of £425,000, subject only to the approval of Parliament. This sum includes the £25,000, which will cover whatever may

Digitized by Google

have been expended on capital account for the benefit of the concern over and above its share capital.

Electric Tramways in Berlin.—According to the latest information from Germany the Berlin police, though consenting to the construction of two electric tram lines intended to connect the city with the Treptow Park, the place of next year's National Exhibition, object to the entire use of the trolley system, and have stipulated that at six different points, mostly squares and important crossing points, the conduit system must be used.

Aelotropic Magnetite.—At a recent meeting of the Société Française de Physique, M. Pierre Weiss gave an account of the results of his experiments on the aelotropic magnetic properties of crystallised magnetite. The magnetisation curve of magnetite crystallised in the cubic system presents the same general features as those of iron, nickel and cobalt. The permeability, however, varies with the inclination of the magnetising field to the crystallographic axes.

Oil Firing for Boilers.—The question of oil firing for boilers, says *Engineering*, is certain to become an important one in the near future. The usual practice has been to spray the oil by a steam jet, and compressed air has also been used for the same purpose. Following, however, the lead of the oil light makers, attempts are now being made to do away with any necessity of spraying the oil, by gasifying it instead. The oil on this system is passed through tubes on its way to the burner, the tubes being maintained at a high temperature by the issuing flame.

Electric Traction in Copenhagen.—A French syndicate, which is co-operating with several local gentlemen, is, says *Engineering*, about to construct two or three electric railways, connecting Copenhagen with various points in the neighbourhood with which there has hitherto been no connection by rail. The first line to be taken in hand is the one to the island of Amak, on which part of Copenhagen is located, and the capital for which is about £50,000. It will be a "ring" railway, and it is under contemplation for the Company to buy up land along the railway, and upon it build labourers' houses, &c.

The Horse Power of a Lightning Stroke.—In a recent issue of the *Archiv für Post und Telegraphie* Prof. Hoppe gives some interesting details of the energy developed by a lightning stroke. At Klausthal a lightning stroke struck the wooden post of a house and fused two nails 4mm. thick. Experiments made afterwards by Messrs. Siemens and Halske, of Berlin, showed that a current of 200 amperes and 20,000 volts was required to do this work in one second. This represents about 7,000 H.P., and taking the duration of the lightning as one-tenth of a second the total power would be ten times as much.

The Protection of Iron and Steel from Rust.—The Gesner method of protecting iron and steel from rust consists, says the *Engineer*, in forming on the surface of the metal a double carbide of hydrogen and iron. The articles to be treated are placed in a gas retort at from 600 to 700°C. for about 20 minutes, when a current of hydrogen is turned into the retort and kept on for 45 minutes. Naphtha is next introduced, the supply being kept on for 10 minutes, and a current of hydrogen for 15 minutes longer finishes the process. The coating thus produced has a bluish colour, and is stated to be so adherent to the metal that a treated bar can be bent through an angle of 45deg. without disturbing it.

Cause of Death from Electric Shock.—According to *Engineering*, Dr. A. M. Bleile, of the Ohio State University, explains the cause of death in electric shock as follows: "Death is due to the fact that the current produces a contraction of the arteries through an influence on the nervous system, and this constriction of the arteries throws in such a mechanical impediment to the flow of the blood as the heart is unable to overcome. Where such a drug as nitro-glycerine or nitrite of amyl is given to counteract this effect, much larger doses of electricity than the ordinary can be borne. Artificial respiration may be of use in cases of simple stunning, but when large quantities of current (*sic.*) pass, no rational means of resuscitation have, as yet, been suggested."

Electric Light in German Mail Cars.—The German postal railway vans are now being all fitted up with accumulators and electric lamps. The principal charging stations are at Berlin, Hamburg, Eisenach and Frankfort. In Berlin the accumulators are charged by dynamos driven by gas engines; in Frankfort, Eisenach and Hamburg they are charged from the local electric mains. In Frankfort the charging is indirect; the high-pressure alternating current is passed through a transformer, and is then employed to run an alternating-current motor which drives a dynamo, which charges the accumulators. It is said, says the *Gas World*, that there is even a saving of 50 per cent. in cost, as compared with compressed gas; and at any rate the post-office officials in the vans seem to be very pleased with the change.

Three-phase Plant for Tramway Work.—The General Electric Company of America is making the first American application of the three-phase long-distance system to street railway work at Lowell, Mass., where a plant is in course of construction for the Lowell and Suburban Street Railway Company. Its special features will render it most interesting. In the first place, the generators will deliver both alternating and continuous current, and when not in use for transmission work will be run in parallel with the railway generators now in the station. They will be wound for delivery of low voltage current at the alternating side, and this current raised to 5,000 volts will be carried to two sub-stations, one 9 miles and the other 14 miles distant from the generating station. The substations will each be provided with suitable step-down transformers of the General Electric air-blast type, as well as two rotary converters.

Phosphorescence.—In a Note in a recent number of the *Comptes Rendus*, M. Gaston Séguy gives the result of some experiments made by him with regard to phosphorescence in electric discharge tubes. As is well known, the phenomenon of phosphorescence is observed in tubes containing rarefied oxygen through which an electric discharge has been passed. In the course of numerous experiments on nitrogen and its components, M. Séguy finds that nitrogen also phosphoresces, at least in the presence of a metallic bichloride. The tube used by M. Séguy consisted of three bulbs, fused together and furnished with electrodes. These were filled with nitrogen obtained from atmospheric air by the Brin process, a vacuum being then made, and the vapour of bichloride of tin being added. If an electric discharge is passed, the tube glows brilliantly, and the glow persists after the interruption of the current. The glow is a reddish colour during the discharge, whilst that of an oxygen tube is a greyish violet. The phosphorescence is a milky white, filling the whole tube with the exception of a few centimetres near the poles. This glow attains a maximum brilliancy immediately after the interruption of the current, and gradually disappears at the end of 10sec. or 80sec.

Niagara Rhetoric.—Under the title of "The Great Convention" *Electric Power* delivers itself of the following: "In hundreds of years from now, when the work of our present generations will simply be remembered as some historical event, when all that remains of the best of us shines out like an insignificant spark, then, yes even then, will this last Convention of our American Institute of Electrical Engineers mark the closing of the first great chapter of power transmission. For the first time were these huge machines revolving, for the first time was power taken off these machines, for the first time were the engineers and their friends brought up to these vast dead masses which fairly seemed to possess life, for they were awe-inspiring, and in their proud and graceful motion these tremendous machines represented to us the outcome of the greatest engineering skill, not of our nation alone, no, of the skill of the best of almost all the civilised world. It was a happy gathering; one felt proud in his fellow-men and co-workers, jealousy did not seem to exist, but admiration and joy prevailed. As far as the power problem is concerned, we have found out the solution; the transmission will undoubtedly present new and unforeseen difficulties which tend not to destroy but to retard the final success of these enterprising companies."

Digitized by Google

Wiring.—At a meeting of the American Institute of Electrical Engineers last April Prof. W. A. Anthony offered some remarks on the subject of wiring which may be of interest on this side of the water. When highly insulated wires, whose insulation resistance was measured in megohms per mile after immersion in water for weeks, came into use for electric lighting plants, it was natural, he said, to suppose that they could be put anywhere, and would last indefinitely. They were put in all sorts of inaccessible places; on the beams before floors were laid, in partitions before plastering, on the lath with iron staples to be covered with mortar. Then came the interior conduit, which it was assumed would serve both as a mechanical protection and an insulator, but it was found not to be entirely reliable in either capacity. It was not impervious to moisture, it was subject to damage by nails, saws and chisels. It was found necessary to prescribe that wire of the highest insulation should be used in it, and that it should not be drawn in until all danger from mechanical injury was passed. Then came the brass-armoured conduit; but that was not nail proof. Now we have the iron-armoured conduit, and it remains to be seen whether this will fulfil all requirements. There has been a uniform progress in the direction of greater safety and better facilities for repair, from the time when wires were put anywhere to be covered by floors, or mortar, or built into brick walls, to the iron-armoured conduit which is offered to-day.

Indirect Electrolysis.—In a communication to *Le Genie Civil* Mr. F. Andreoli describes a curious experiment on indirect electrolysis. Taking a cell divided into three compartments by porous diaphragms, a solution of any salt is placed in the central compartment, whilst the two electrodes are placed in the side compartments immersed in similar or different electrolytes. The decomposition of these latter is, on the current being passed, effected as if the central compartment did not exist, the solution in it being unaffected. In this form the experiment is an old one, but Mr. Andreoli finds that if a plate or series of plates is placed in the solution in the central compartment, reactions occur which can only be attributed to an indirect or secondary electrolysis. If, for example, the two outer compartments are filled with a solution of common salt, and the central one with a solution of cyanide of gold. Let the anode in the one compartment be of carbon, and the cathode in the other of iron. On passing a current under these conditions chlorine is evolved at the carbon electrode and caustic soda produced at the other, the cyanide solution being, as aforesaid, unaffected. If, however, whilst the current is passing, a series of metal plates are immersed in the cyanide solution, the gold is deposited on them, though neither chlorine nor soda appears to pass into the central compartment.

Science Scholarships at Cambridge.—Though only nine colleges offer entrance scholarships in science, an examination of the awards to the first, second and third year students shows, says *Nature*, that science, as tested by University or inter-collegiate examinations, does not go unrecognised. A large body of medical students, now approaching 500 in number, is distributed over all the colleges, and their presence has apparently brought home, even to the most conservative, the fact that intellectual ability, high-minded devotion to study, and social energy are not confined to students of classics and mathematics alone. Thus, though something remains to be done in certain quarters in the direction of placing science on an equal footing with the older subjects, it would appear that great advance has been made within the last ten years. The natural science tripos now attracts a larger number of candidates than any other, and this notwithstanding that its standard has been steadily raised. In the majority of the colleges distinguished eminence in this tripos has been admitted as a qualification for a fellowship, and in not a few instances governing bodies have felt the need of strengthening themselves on the side of science, and have departed from the Cambridge custom by selecting scientific members of other colleges for this honour. Scholarships and fellowships have of late years been substantially increased. Our contemporary then goes on to say that post-graduate studentships, which are expressly intended to foster advanced study and research, have already produced excellent results, although the University still lacks the means of providing for such encouragement in higher work in chemistry, physiology, scientific engineering, &c. It is to be hoped, says our contemporary, that the race of generous benefactors is not extinct, and that some of these important subjects may ere long receive the benefit of their munificence.

The Influence of Moving Matter on the Ether.—The problem of the motion of ether with or through ordinary matter has been again attacked by Herr L. Zehnder, who recently contributed an interesting paper on the subject to *Wiedemann's Annalen.* He endeavoured to ascertain whether the ether is pushed along by atoms, or whether it passes through their substance without resistance, or, finally, whether only a portion of the ether adheres, and this portion only is carried along. Herr Zehnder's apparatus consisted of a cast-iron cylinder in which an air-tight piston moved. A small tube led out from one end of the cylinder, doubled back upon itself, and returned to the other end. Now, if the cylinder was exhausted of air, so as to leave nothing but ether behind, and the piston was then worked, the inference would be that the ether would stream through the small tube with a velocity as much above that of the piston as the ratio of the sectional area of the one to the other. This ratio was 560 to 1; and exhaustion was carried to the 40,000th part of an atmosphere. To ascertain whether the ether moved in the sense contemplated, a beam from a brilliant sodium flame was passed through two thick parallel glass plates; the second one being silvered at the back. This plate, by its two reflecting surfaces, split the beam of light into two, each part travelling through one portion of the small tube. Then the same beams were reflected back upon the thick plate, and returned along the way they had travelled, being finally reflected into the reading telescope by the first plate. Interference fringes were thus produced in the field of view, the motion of which would have indicated a movement of the ether; but no such motion was observed when the tubes were thoroughly exhausted, so that it was concluded that the ether passes through solid bodies. A similar negative result has been obtained by Dr. Oliver Lodge and others, in the efforts they have made to discover if there is any molecular drag on the ether.

Niagara.—The following letter has been addressed to the editor of *The Times* by Mr. F. L. Stetson, the first vice-president of the Cataract Construction Company, and appeared in that paper last Saturday :—

Sir: In your issues of Saturday, yesterday, and to-day appear letters from Prof. George Forbes and Lord Kelvin concerning the adoption of the alternating current for the electric power installation at Niagara, and referring to the advice given by them to the Directors of the Cataract Construction Company, which did the work. As first vice-president of that Company, which sought and gladly received the advice of these two eminent engineers, I feel it due to both of them that the facts should be stated briefly as follows: 1. In January, 1891, Lord Kelvin was chairman, and Prof. Forbes the submitter of a project, to the International Niagara Commission. At the close of that commission every one condemned and rejected the alternating system, excepting only Prof. Forbes and Messrs. Ganz and Co., of Budapest. 2. In January, 1894, the Niagara Directors had adopted the alternating system upon the advice of Prof. Forbes, and with the concurrence of all the expert advisers, including those who had rejected the alternating system in 1891, excepting only Lord Kelvin. Lord Kelvin thereupon sent to us a cable, in which he certainly indicated a strong preference for the continuous current, but intended also (as we are now gratified to learn from him) as recognising that we "could certainly succeed with the alternate current." 3. Our decision was thus made because of the prohibitive cost of the continuous current installation, which in most particulars fully justified the strong preference for it evinced by Lord Kelvin, whose eminent and valuable advice and encouragement we gratefully acknowledge. Except for his early and original support, our plan would have died "a-borning," and we thank him for his continuing interest. 4. But the development of our plan must have been long delayed had it not been for the courage and comprehensive knowledge of Prof. Forbes, who alone stood for the absolute commercial advantage of the alternating current, and for his admirable conception of his 5,000 H.P. dynamo, so wonderfully worked out by the Westinghouse Company as to yield 5,315 H.P. in the actual test on June 28, 1895. Prof. Forbes is entitled to the credit, as he must bear the responsibility, of the results of the advice given by him as to the three points stated in his letter of July 25th; and we have followed his advice, perhaps not as far as his courage would carry him, yet beyond the former practice of the manufacturers, who now fully concur in the wisdom of his recommendations as adopted. The rotary transformers approved by Prof. Forbes and made by the General Electric Company are worthy of the highest praise for both design and execution. 5. In fine, the extraordinary and gratifying progress in the development of transforming apparatus, and a corresponding reduction of cost, have taken away many, if not all, of the reasons which Lord Kelvin gave against the adoption of Prof. Forbes's original recommendation of the alternating current, which now, as he truly says, "alone solves the problem well and economically."

ELECTROMAGNETIC THEORY.—LXXII.*

BY OLIVER HEAVISIDE.

(*Continued from page 348.*)

§ 279. I have said rather more about Fourier's theorem than I meant at first. That is a good enough reason for adding one more § about it, in order to have done with it. The way Fourier's theorem presents itself in the theory of functions—that is, in *the* theory so-called thereof, which is manifestly confined to limited notions of a function—is worthy of notice. The complex variable has a double variability, and may be represented by the position of a point in a plane. But a circuital journey round the origin in the plane brings us back to the starting point. In this process the variable θ increases by the amount 2π. So we have necessary periodicity of functions of the position of the point, in the manner of Fourier's theorem, which is therefore essentially involved in the expansion of complex functions of position in integral powers of the variable denoting the position of a point in the plane.

Thus, there is Laurent's theorem for the expansion of a holomorphic function. Let $f(z)$ be the function, where z is the complex $re^{i\theta}$, r and θ being the polar co-ordinates. Assume that f is capable of representation in integral powers of z, positive and negative, say

$$f(z) = A_0 + A_1 z + A_2 z^2 + \ldots + A_{-1}z^{-1} + A_{-2}z^{-2} + \ldots$$
$$= \Sigma_{-\infty}^{\infty} A_n z^n. \qquad (109)$$

Then we may easily determine the coefficients. The mean value of z^m, regarded as a function of θ, round a circle centred at the origin, is zero when m is any integer, except zero. In that exceptional case the result is 1. So, multiplying equation (109) by z^{-n}, and integrating with respect to θ, round a circle centred at the origin, we get

$$\frac{1}{2\pi}\int_0^{2\pi} f(z)z^{-n}d\theta = A_n. \qquad (110)$$

That is, the value of A_n is the mean value of $f(z)z^{-n}$ with respect to θ. So, by (109) and (110), we have

$$f(z) = \frac{1}{2\pi}\int_0^{2\pi} f(z')d\theta' \, \Sigma_{-\infty}^{\infty}\left(\frac{z}{z'}\right)^n. \qquad (111)$$

This is Fourier's theorem generalised by the introduction of the powers of r. To obtain it explicitly, make $r = r^1$, so as to be concerned only with a function of θ. Then we get Fourier's theorem:—

$$f(\theta) = \frac{1}{2\pi}\int_0^{2\pi} f(\theta')d\theta' \Sigma_{-\infty}^{\infty} \epsilon^{in(\theta-\theta')}$$
$$= \frac{1}{2\pi}\int_0^{2\pi} f(\theta')d\theta' \Sigma_{-\infty}^{\infty} \cos n(\theta - \theta'). \qquad (112)$$

The substitution of the cosine for the exponential function occurs because the imaginary part of the latter contributes nothing to the result. The nth term cancels the $-n$th in this respect. But the imaginary part must not be omitted in the more general result (111).

For a rigorous demonstration of Laurent's theorem see works on the theory of functions. The line of integration may be any circle within the holomorphic region, so Laurent's theorem is the natural sequence to Fourier when the distance from the origin is not invariable, and when the function is controlled by the restricted functional notions. The variations with r and with θ are not independent. The values of the function on one circle control those on another.

It would be of some interest to know how the function theorists would treat the subject of Fourier's series in general, referred to the complex. In the above, the expansion is the rudimentary one in integral powers of the variable. In general, fractional powers are required, the n's following some special law. Say, for example, that $f(z)$ is given on the circle of z'. Then we require to have

$$f(z) = \Sigma A_n z^n, \qquad (113)$$

so as to be right for the given circle, and, in addition, to satisfy certain boundary conditions. For example, make a radial slit in the plane at $\theta = 0$, and let the function have to satisfy a given linear differential equation between it and its derivatives with respect to θ on one side of the slit, where $\theta = 0$, and another similar equation on the other side, where $\theta = 2\pi$. This case corresponds to that of a cable subject to terminal but not to extra intermediate conditions. The infinite series of n's, which may be real or imaginary, will follow a law depending upon the conditions at the slit; and the determination of the coefficients A may be effected by a definite conjugate property, not that of the vanishing of the mean value of z^n round a circle as before mentioned, but of a more general character determined by the conditions at the slit. I have looked into Forsyth's work to see if there is anything about these expansions in fractional powers of the variable, but without success. If the matter has not been investigated, there is room for much expansion of the subject of the determination of functions, especially when one thinks of the various extensions that may be given by the introduction of intermediate differential conditions. Matters of this sort do not present much difficulty in strictly physical problems, and the corresponding cases in the function theory would, perhaps, involve little more than formal changes. At the same time, I must say that a matter which may be sufficiently clear in physical mathematics may become much obscured by a deliberate removal of the physical ideas, which is, perhaps, the reason of the existence of such elaborate and disagreeable demonstrations for the sake of rigour, of supposed or real necessity. It is a serious question whether the study of the theory of functions ought to be taken up by any ordinary physical student. Of course, some useful knowledge of the complex is necessary, and no one could fail to pick up some as he goes along by ordinary algebra; but that is quite different from the theory of functions as elaborated, the general tone of which is quite unlike that of the usual physical mathematics. The frame of mind required is not one that is conducive to progress in mathematical analysis in its physical aspect. A man would never get anything done if he had to worry over all the niceties of logical mathematics under severe restrictions; say, for instance, that you are bound to go through a gate, but must on no account jump over it or get through the hedge, although that action would at once bring you to the goal.

§ 280. After this little excursion to the borders of the realms of duplicity and fearful rigour, we may return to the proper subject. We have to see how the general operational solutions must be treated in order to convert them to the appropriate Fourier series, by which (in one way) they become amenable to numerical calculation. It may be remembered that I have insisted upon the definiteness and fulness of meaning of an operational solution, and that it contains within itself not only the full statement of the problem, but also its solution. No external aid is therefore required to algebrise it fully; no assumption, for instance, of a special type of solution, and that the solution is the sum of a number of that type, with subsequent determination of the constants required to complete the matter. The work of satisfying the imposed conditions has been done already.

The conversion to algebraical or quantitative form may be easy or hard, self-evident or very obscure. But in any case it is possible, by the prior construction of the operational solution. Thus, the conversion furnishes a distinct subject of study which is of great practical value from the physical standpoint. As regards finding out how to effect the conversion, that is a matter principally of observation and experiment, and is in a great measure independent of logical demonstrations. It is the How, rather than the Why, with which we are mainly concerned in the first place; though, of course, parts of the Why cannot fail to be perceived in the course of examination of the How. A complete logical understanding of the subject implies the existence of a full theory to account for why certain ways of working are successful, and others not. It is important to note that it is just the same in mathematical research into unknown regions as in experimental physical research. Observation of facts and experiment come first, with merely tentative suggestions of theory. As the subject opens out, so does the theory improve. But

* This series of articles is a portion of Vol. II. of Mr. Heaviside's work on "Electromagnetic Theory." All rights of reproduction are reserved.

Digitized by Google

it can only become logical when the subject is very well known indeed, and even then it is bound to be only imperfectly logical, for the reasons mentioned at the beginning of this volume. I feel inclined to be rather emphatic on the matter of the use of experiment in mathematics, even without proper understanding. For there is an idea widely prevalent (though it may not receive open expression) that in mathematics, unless you follow regular paths, you do not prove anything; and that you are bound to fully understand and rigorously prove everything as you go along. This is a most pernicious doctrine, when applied to imperfectly explored regions. Does anybody fully understand anything?

Three of the pernicious results of overmuch rigour may be mentioned here. First, its enfeebling action on the mind, sufficiently indicated by the analogy at the end of the last §. Secondly, it leads to the omission from mathematical works of the most interesting parts of the subject, because the authors cannot furnish rigorous proofs. Thirdly, it leads to an inability to recognise the good that may be in other men's work, should it be unconventional, and be devoid of rigorous pretence.

It may not be necessary to algebrise an operational solution. It may not even be desirable to do so, if the meaning is sufficiently plain in operational form, and the algebrisation produces complication. This is very often true when the operations are merely direct ones, as, for example, $(a+bp+cp^2+\ldots)e$, where e is the operand and p the time differentiator. But it is also true, up a certain point, in more advanced forms. Consider, for instance $(XY)^{\frac{1}{2}}e$, or $(X/Y)^{\frac{1}{2}}e$, or $R^m e$, where X and Y, or R, are operators of the form $a+bp$. If the operand e is a simply periodic function of the time, we do not require to algebrise these forms in order to see their meaning. We can do that by geometrical construction in the now well-known manner founded upon the property $p^2=-n^2$, or $p=ni$, representing X and Y by rotations of vectors in a plane. But if we desire close calculation of the results, it is desirable to have the full algebraic formula. Again, I see that Mr. Kennelly has lately dispensed with the use of the full development in the more complicated cases of the shin and cosh of a complex (the complex corresponding to $a+bp$), by means of a specially constructed diagram. I do not doubt that certain cases in which e is impulsive or steady can be done by diagram. It is best, however, to do the work analytically first, in general, at least as far as the operational solution itself, and then see if, in a reasonable time, a geometrical method of representing it is suitable for calculation. For geometry by itself is rather a heavy and clumsy machine. Remember its history, and how it went forward with great bounds when algebra came to its assistance. Later on, the assistant became the master.

The special ways which I have so far given of turning operational solutions of the diffusive kind to Fourier series have all been applied to elementary examples, the terminal conditions being such that the roots of the determinantal equation have been equally spaced, as π, 2π, &c., or $\frac{1}{2}\pi$, $1\frac{1}{2}\pi$, &c. Algebraic simplicity is thereby attained, and we are allowed to use well-known trigonometrical expansions. But, in general, the roots of the determinantal equation $\epsilon^{2ql}=\alpha\beta$, where α and β are functions of p depending on the terminal conditions, are not equally spaced, and they may not be all of the same kind—that is, they may be (as regards s in the circular functions) real or imaginary. The elementary expansion formulæ are useless. There are now three ways that present themselves of attacking the question.

First, to follow up Fourier's way by natural extensions of the kind to be found by experience. Assume the existence of a normal solution of the form

$$v=A\sin(ax+b)\epsilon^{Pt}.$$

Apply it to the actually stated problem. Find the connection between P and a so as to satisfy the characteristic equation of diffusion. Next find, by applying the terminal conditions to the above assumed solution, what relation exists between a and b. Then find the law followed by the a's, and find their values. We thus get an elementary type solution fully determined except as regards size, and we know that every admissible value of a gives a solution.

Next, assume that

$$V=\Sigma v_n=\Sigma A_n\sin(a_n x+b_n)\epsilon^{P_n t},$$

where the summation includes all the values of a_n, is the form of the solution of the special problem, namely, the sum of any number of the type solutions. Only the A's are arbitrary. To find them, observe that $t=0$ makes

$$V_0=\Sigma A_n\sin(a_n x+b_n).$$

The summation on the right therefore represents the initial state. Given the initial state V_0 as a function of x, we require to determine the A's in accordance therewith.

This may be done by finding the conjugate property possessed by the normal functions. When known, it allows us to operate on V_0 by quadratures in such a way as to isolate any single coefficient and determine its value. Finally, introducing the time factor, we arrive at the complete solution as regards the effects due to a given initial state, provided the effects are entirely due thereto. And the effect due to an impressed force may be done similarly by considering the final state it produces, and allowing that to discharge itself in the above manner.

The process of finding A_n is, when the terminal conditions are of the simple kind previously considered, sufficiently obvious. The integral of the product of two normal systems vanishes save when they are alike. But with terminal conditions in general, with energy involved in the terminal apparatus, it is quite another thing. The conjugate property is not the same, and although fundamentally simple in meaning, works out more difficultly. The determination of the A's may become a complicated process, requiring careful investigation of the terminal arrangements themselves. It depends upon the vanishing of the excess of the electric over the magnetic mutual energy of a pair of different normal systems (with different values of p, that is to say). In doing this, the two terminal arrangements have themselves to be included, if any part of the energy is located therein.

§ 281. As a second way, we may follow up the special ways of operationally working already given in connection with simple terminal conditions. First, find the operational solution. Next investigate the proper expansions in partial fractions of the reciprocal of the determinator $(\epsilon^{2ql}-\alpha\beta)$ which occurs in the operator, wherein p has to have all the values which make it (the determinator) vanish. The integration of the partial fractions follows. Complete the solution by carrying out what may be left in the way of direct operations. The expansions required are analogous to those of $\coth ql$ and other functions already used. But this process may be rather difficult, since the theory of partial fractions may lead one into obscure regions of the complex.

Finally, there is a third and very general way of converting operational solutions to the form of the sum of normal solutions. It does not require special investigation of the properties of the normal functions. It is very direct and uniform of application. It avoids, in general, a large amount of unnecessary work. The investigation of the conjugate property, and of the terminal apparatus in detail in order to apply it to the determination of the coefficients, is wholly avoided. It applies to all kinds of series of normal functions, as well as to Fourier series. And it applies generally in electromagnetic problems, with a finite or infinite number of variables; or, more generally, to the system of dynamical equations used by Lord Rayleigh in the first volume of his treatise on Sound, which covers the rest of the work, and upon which he bases his discussion of general properties.

The method may be briefly (though imperfectly) stated as follows: Let $e=ZC$ be the operational solution of an electromagnetic problem; say, for definiteness, that C is the current at a certain place due to an impressed force, e, at the same or some other place. Let the form of Z be such as to indicate the existence of normal solutions for C. Then, when e is steady, beginning at the moment $t=0$, the C due to e is expressed by

$$C=\frac{e}{Z_0}+e\Sigma\frac{\epsilon^{pt}}{p\frac{dZ}{dp}}\quad\ldots\ldots\quad(1)$$

to be understood thus:—

In the first place, the Z in the operational solution is an operator, a function of p the time differentiator. But in

Digitized by Google

equation (1) Z, is entirely algebraical. Thus, Z_0 is the algebraical function obtained by putting $p=0$ in Z. It is the effective steady resistance to e when, as supposed, e is a voltage, and it is at the place of C. Otherwise it is more general. Then, in the summation, dZ/dp is the ordinary differential coefficient of Z with respect to p as a quantity. Lastly, the summation ranges over all the roots of the algebraical equation $Z=0$, which is, in this respect, the determinantal equation, though Z itself is much more. These special values of p are to be used in dZ/dp as well as explicitly.

Instead of a C due to an e, it may be V due to e, or V or C due to an initial charge at a point, and many other variations might be mentioned. But it must not be inferred that equation (1) expresses a general mathematical property independent of the form of Z. Dynamical conditions restrict the form in certain ways, for one thing. But it is not even true that the expansion theorem above holds good in strictly dynamical problems. I have already pointed out that we require barriers or boundaries to produce definite and finitely separable vibrating normal systems. Also that in the cable problem, subject to terminal conditions, the determinator $\epsilon^{2ql}-\alpha\beta$ which occurs as a denominator in the general operational solutions arises from the coexistence of successively (though apparently simultaneously) generated waves. So all sorts of problems are immediately excluded from the expansion theorem, at least in the form of equation (1). Inspection of the operational equations will show this, or else physical considerations. Again, the real Z may be the sum of two operators, to one of which the expansion theorem applies fully, whilst the other requires a different treatment. It may involve direct operations of an obvious nature.

Now it would be useless to attempt to state a formal enunciation to meet all circumstances. Even supposing that an absolutely perfect knowledge of the subject made it possible to do so, it would be very unpractical. It would be worse—far worse—than that very lengthy enunciation of a theorem in the 5th Book of Euclid, which may be read and re-read fifty times without properly grasping its meaning, which is not much, after all; only something in compound proportion that the modern schoolboy does in a minute or two. It is better to learn the nature and application of the expansion theorem by actual experience and practice. A theorem which has so wide an application is a subject for a treatise rather than a proposition.

So, to begin with, I will give a few elementary cases concerning one or two degrees of freedom, just to show how the expansion theorem goes, and how to discriminate different forms of Z. After that, we can apply it to diffusion problems in the same way. Other than diffusion problems coming under the same theorem may occur later. And when the reader knows how to work the theorem, it may be possible to see its inner meaning. At present all that need be said is that in its theory it contains the first method of evaluating the coefficients by the conjugate property, and also the second method involving partial fractions. Only it jumps over most of the difficulties connected with both.

(To be continued.)

LINES OF FORCE.

BY W. G. RHODES, M.Sc.

The equation to a line of force due to two equal magnetic poles has been obtained in the form

$$\cos\theta \pm \cos\phi = constant,$$

where the upper sign refers to unlike poles, and the lower sign to like poles; also θ is the angle which the line joining the poles makes with the line joining one of the poles to a point on a line of force, and ϕ is the corresponding angle for the other pole. The field of force due to the two poles is plotted by giving different values to the constant.

The following is a determination of the equation of a line of force due to any two poles, irrespective of magnitude and sign.

Let A (Fig. 1) be a magnetic pole of strength m_1 and B one of strength m_2. Take the middle point, O, of A B as origin, and A B and a line through O perpendicular to A B as axes of x and y respectively.

Let P be any point whose co-ordinates are (x, y),

$AP=r_1$, $BP=r_2$, $AB=2a$,

Angle $PAB=\theta$ and angle $PBA=\phi$.

Then
$$\left.\begin{aligned} r_1^2 &= (a+x)^2+y^2 \\ r_2^2 &= (a-x)^2+y^2 \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (1)$$

Now, if V is the potential at P due to m_1 at A and m_2 at B, we have

$$\frac{m_1}{r_1}+\frac{m_2}{r_2}=V. \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

If we displace P to a consecutive point on the equipotential surface through P, and in the plane of the paper, we have

$$\frac{m_1}{r_1^2}dr_1+\frac{m_2}{r_2^2}dr_2=0. \quad . \quad . \quad . \quad . \quad (3)$$

Also from (1) $\quad r_1\,dr_1=(a+x)\,dx+y\,dy$
and $\quad r_2\,dr_2=-(a-x)\,dx+y\,dy$.

Substituting in (3) and reducing, we get

$$y\left(\frac{m_1}{r_1^3}+\frac{m_2}{r_2^3}\right)\frac{dy}{dx}+\frac{m_1}{r_1^3}(a+x)-\frac{m_2}{r_2^3}(a-x)=0. \quad . \quad (4)$$

This is the differential equation of the traces of the equipotential surfaces on the plane of the paper.

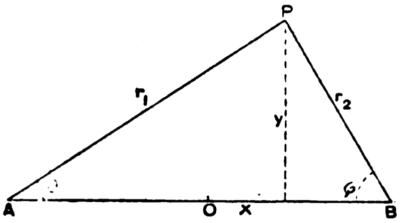

FIG. 1.

Since the lines of force cut the equipotential surface everywhere at right angles, the differential equation of the system of lines of force is

$$\left\{\frac{m_1}{r_1^3}(a+x)-\frac{m_2}{r_2^3}(a-x)\right\}\frac{dy}{dx}=\left(\frac{m_1}{r_1^3}+\frac{m_2}{r_2^3}\right)y, \quad . \quad (5)$$

writing $-\dfrac{1}{\frac{dy}{dx}}$ for $\dfrac{dy}{dx}$ in (4).

To integrate (5) put

$$a+x=y\cot\theta, \qquad a-x=y\cot\phi,$$

and
$$r_1=y\operatorname{cosec}\theta, \qquad r_2=y\operatorname{cosec}\phi,$$

so that
$$\frac{dy}{dx}=-\frac{\operatorname{cosec}^2\theta\,d\theta+\operatorname{cosec}^2\phi\,d\phi}{\operatorname{cosec}^2\theta\cot\phi\,d\theta-\operatorname{cosec}^2\phi\cot\theta\,d\phi}.$$

Substituting these values in (5) we obtain, after a little transformation,

$$m_1\sin\theta\,d\theta-m_2\sin\phi\,d\phi=0;$$

and integrating,

$$m_1\cos\theta-m_2\cos\phi=constant,$$

or
$$\cos\theta-k\cos\phi=constant, \quad . \quad . \quad (6)$$

where $k=\dfrac{m_2}{m_1}$.

The corresponding Cartesian equation is

$$\frac{a+x}{\sqrt{\{(x+a)^2+y^2\}}}-k\cdot\frac{a-x}{\sqrt{\{(a-x)^2+y^2\}}}=constant. \quad (7)$$

By giving a suitable value to the constant the equation to any line of force may be obtained.

Two cases arise according as k is negative or positive; that is, according as the two poles are unlike or like.

If k is *negative*, so that equation (6) becomes

$$\cos\theta+k\cos\phi=constant,$$

Digitized by Google

where k is now a mere ratio, we can obtain successive points on lines of force as follows:—

Let A (Fig. 2) be the position of m_1,
B (Fig. 2) be the position of m_2,
$AB = 2a$.

Describe a circle with A as centre, and of any radius d. With B as centre describe another circle of radius kd. Draw any line C D M at right angles to A B, and cutting the circles

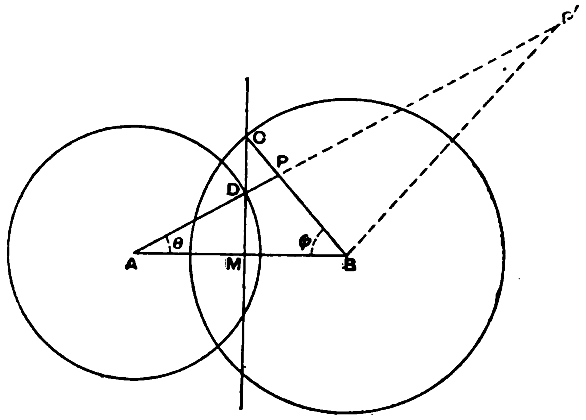

Fig. 2.

in the points C and D. Let B C and A D, or their elongations, intersect in P.

Then
$$\cos\theta + k\cos\phi = \frac{AM}{AD} + k.\frac{MB}{BC}$$
$$= \frac{AM + MB}{d}$$
$$= \frac{2a}{d} = constant.$$

Thus, as M describes the line A B, P will describe a line of force.

If k is positive, so that equation (6) becomes
$$\cos\theta - k\cos\phi = constant,$$
the following additional construction is necessary:—Produce A P (Fig. 2) to P′ and draw B P′, so that angle A B P′ $= \pi$ − angle A B P. Then
$$\cos P'AB - k\cos P'BA = \cos PAB + k\cos PBA$$
$$= \frac{2a}{d}.$$

P′, then, is a point on a line of force which it will describe as M describes the line A B. By taking different values of d the whole field of force may be plotted. The author is indebted to his colleague, Mr. G. C. Turner, for suggesting the additional geometrical construction which determines the point P′ (Fig. 2).

In the particular cases of equal like, or unlike, poles, $k = \pm 1$ and equation (6) becomes
$$\cos\theta \mp \cos\phi = constant.$$
The same geometrical construction still holds good, the radii of the two circles (Fig. 2) now being equal.

HORIZONTAL CARBON PROJECTORS.

BY E. A. N. POCHIN, B.A.

Anyone who has watched the improvements made in projectors during the last few years cannot fail to have noticed that whilst the energies of makers have been directed towards obtaining mirrors of better quality, little or nothing has been done to produce a lamp which will use these improved mirrors to the greatest advantage. The projector lamp with inclined carbons, introduced by Sautter Lemonnier, undoubtedly possesses many good points, in virtue of which it has been very largely copied by other makers. At the same time it suffers from certain defects which appear to have escaped observation, and which are due to the inclined arrangement of the carbons. The usual position, too, of the arc with regard to the mirror, renders the combination far less effective than it might be. In a 100-ampere 24in. projector of the most usual type, the arc is situated 17in. or 18in. from the mirror, and this accordingly embraces a cone of light having a solid vertical angle of about 21 per cent. of a hemisphere, whilst the light from the arc is spread over a hemisphere. Consequently, although the mirror is situated in the best illuminated region, a very large proportion of the light falls on the sides of the projector and is wasted. In order to obtain some rough idea of this waste, the question will be treated mathematically.

Let us assume that the crater is a small disc on the axis of the mirror, at right angles to this axis and luminous on the side facing the mirror. The intensity of the light in any direction will then vary as the cosine of the inclination θ to the axis. The semi-vertical angle of the cone of light falling on the mirror is about 38deg., and therefore the ratio of the light received by the mirror to the total light is represented by

$$\frac{\int_0^{38^\circ}\sin\theta\cos\theta\,d\theta}{\int_0^{90^\circ}\sin\theta\cos\theta\,d\theta} = \frac{\left[\sin^2\theta\right]_0^{38^\circ}}{\left[\sin^2\theta\right]_0^{90^\circ}} = 38 \text{ per cent. approximately.}$$

No special accuracy is claimed for this method; but the result obtained is probably not very far from the true figure. In

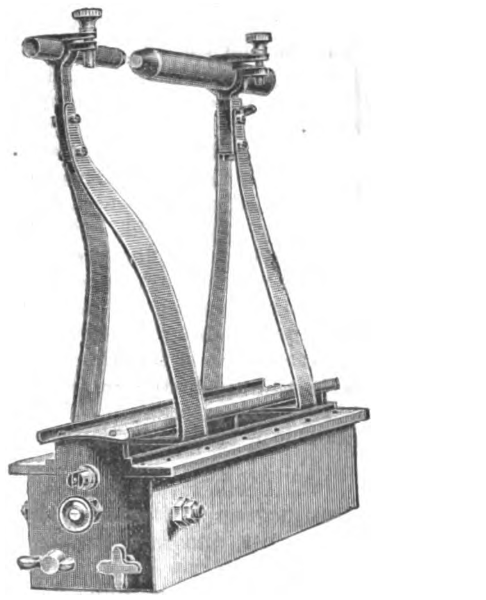

Fig. 1.—Crompton Automatic and Hand-feed Lamp.

addition to this, about 35 sq. in. of the beam is obstructed by the carbons, their supports, and the usual carbon block. Thus, out of the 38 per cent. of useful light obtained, a further 8 per cent. is lost in the manner indicated; the total efficiency of the system being only about 35 per cent.

All those who have worked with inclined lamps of large size must be familiar with the frequent unsteadiness of the arc, accompanied by a loud hissing noise. When this occurs, the arc may be seen to leave its true crater—of which the graphite core is the centre—and try to establish a new crater on some hard portion of the positive carbon, to which there is a shorter path from the negative carbon. If the carbons were placed in line, as in the case of an ordinary arc lamp, and worked at a current not exceeding 50 or 60 amperes, the crater would always remain in its normal position, and there would be no flickering or hissing. The plan of working the arc on the sides instead of at the ends of the carbons is one calculated to encourage flickering, especially with heavy currents.

Fig. 1 shows an automatic and hand-feed lamp, by Messrs. Crompton, which overcomes these objections to a very large degree; and Fig. 2 shows this lamp in combination with a special short-focus mirror. The author has had considerable facilities for making photometric tests with this type of projector, and the figures obtained bear out the statement that

Digitized by Google

this arrangement is about two and a-half times as efficient as the usual pattern of projector of the same size. Tests made by some foreign naval and military authorities employing the Schuckert projector—which also uses horizontal carbons—corroborate these results. The increased efficiency obtained by them was given at 2·8 to 1, and it is only reasonable to suppose that the use of a shorter focus mirror should enable one to accept the above figure with some confidence.

Now, it must not be hastily assumed that a projector of the kind illustrated will give nearly three times as powerful a beam as an ordinary projector when worked at 100 amperes. It would undoubtedly do so for a short time, but as the mirror has been placed so much closer to the arc that it collects nearly three times the light, there would be a great risk of blistering the silver. The real point is, that with about 45 amperes a beam can be obtained having an intensity some 25 per cent. greater than an ordinary 100-ampere projector. The saving to be effected is in the cost of the dynamo, engine, and fuel, which are reduced by some 50 per cent. for the same candle-power. Also, where portability is an object, a similar reduction in weight is of the highest importance.

The following description of the lamp may, perhaps, be of interest to the reader. The carbons are placed horizontally, so that the crater of the positive carbon faces the mirror. The carbon supports are made of sheet phosphor-bronze placed

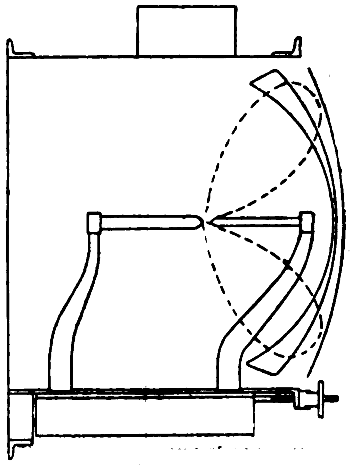

FIG. 2.—Crompton Automatic and Hand Feed Lamp, with Special Short Focus Mirror.

edgeways to the light, and only about 2 sq. in. of the beam is obstructed by them and the carbons. These supports are mounted on carriages placed below the barrel of the projector, and are capable of sliding on grooved rails, which form the upper portion of the box. The position of the carriages is controlled by means of a right and left-handed screw, provided with a milled head at one end and a ratchet wheel and sleeve coupling near its middle point. An electro-magnet in series with the main current strikes the arc by moving one-half of the screw longitudinally. The duty of maintaining the arc at a constant length is performed by an electromagnetic trembler in shunt across the arc. This trembler works the ratchet wheel, thus causing the screw to revolve and the carbons to approach one another. If it be desired to work the lamp by hand, it is only necessary to turn the star handle through half a revolution to disconnect the automatic gear both mechanically and electrically. The carbons can then be controlled by the milled head. The wing nut handle is for the purpose of adjusting the length of arc to which the automatic gear feeds the carbons. Only one focussing motion is necessary, as the arc is always on the axis.

Mechanical Propulsion on Common Roads.—M. Hospitalier has published an account of the accumulator carriages that took part in the recent race to Bordeaux and back. The figures show that these carriages have no chance whatever in competition with those driven by gazolene motors.

NOTES ON HYDRAULIC POWER SUPPLY IN TOWNS.*

BY EDWARD B. ELLINGTON.

The distribution of hydraulic power in towns has not previously been brought directly before the members of this Institution, and the fact that works of this character have just been completed in Glasgow renders the present meeting a suitable opportunity for dealing with an engineering subject of such continually increasing importance.

Existing Hydraulic Power Works.—The present position of the various undertakings which have been established for this purpose is summarised in the accompanying Table I.

General Arrangement.—Of the hydraulic power works in London full particulars have already been given to the Institution of Civil Engineers, and as all such works have much in common it is hardly necessary to add any detailed account of the most recent establishments in Glasgow and Manchester. The supplies in these towns differ from those given elsewhere in the higher pressure employed, namely, 1,120lb. per square inch. The engine house in each city is laid out to contain six sets of vertical triple-expansion engines of 200 I.H.P. each, of the kind introduced by the author in 1880, but in the earlier engines the cylinders were arranged compound with one high-pressure and two low-pressure cylinders. The scale on which the two stations have been planned is the result of the experience gained in London, which has demonstrated that for hydraulic power supply a station of about 1,200 H.P. is the most economical both in working expenses and in outlay of capital.

Delivery.—Each set of engines is designed to deliver 230 gallons per minute at a speed of 60 revolutions, or 240ft. of piston; but it is not intended that they should be run in regular work at more than 50 revolutions, or 200ft. per minute. Assuming that five engines are working at the same time, the total regular working capacity of the stations when fully equipped is 57,500 gallons per hour at 1,120lb. per square inch. The maximum recorded during regular work in an hour at the Wapping station of the London Hydraulic Power Company with five engines running has been 66,000 gallons at 800lb. per square inch, or an average for each of the five engines of 45 revolutions per minute. The reason for dividing the power at a station into so many units is, of course, that the demand for power, as for lighting, is so irregular that the maximum demand is maintained approximately for only an hour or two during any day.

Water.—Both in Manchester and in Glasgow the water supply is taken from the Corporation mains; so that no pumping is required to fill the tanks, and no filtering apparatus is needed. The whole arrangement of these stations is thereby much simplified as compared with those in London, where Thames or canal water is used; it is also unnecessary to have the same large reserve of water in the tanks. At the Wapping station in London, for instance, the tanks over the boilers have a total capacity of 237,000 gallons, and in addition there are underground reservoirs of filtered water containing 500,000 gallons. In Manchester and in Glasgow the whole storage provided is only 230,000 gallons and 200,000 gallons respectively. The pipes in the engine and boiler houses are all arranged on the duplicate or circuit system, and great attention has been given to the provision of sufficient access to all parts of the machinery.

Mains.—The supply from the stations in Manchester and Glasgow is taken to the streets through four mains, which are laid in circuit, with valves at intervals of about 440 yards. Connecting mains have a valve at each end, so that the majority of buildings supplied have two ways by which the power can be obtained. The largest mains laid in Manchester are 6in. internal diameter, and in Glasgow 7in.

Automatic Flow-Recorders.—In order to maintain a sufficient control over all these sources of waste, it is of the first importance to know the minimum flow through the mains at times when it may be supposed that no work is being done. To ascertain this, automatic recorders are fitted at all the pumping stations. The following are the maximum and minimum registrations in London for the June quarters from 1888:—

Year.	Total water pumped in June quarter. Galls.	Maximum flow per hour. Galls.	Minimum flow per hour. Galls.	Annual load factor.
1888 ...	29,238,000	39,120	1,200	0·286
1889 ...	39,873,000	49,920	1,776	0·328
1890 ...	48,172,000	61,248	1,604	0·306
1891 ...	65,386,000	79,330	3,360	0·339
1892 ...	77,103,000	91,920	3,984	0·326
1893 ...	82,586,000	101,760	4,500	0·323
1894 ...	96,876,000	114,096	4,800	0·338

* Including £56,000 for new site and station, started October, 1894. † Including £400 for water rights and £129 for gas lighting. ‡ Wapping station only; output 174,000,000 gallons in 1894. § Davies-street only; output 1,306,794 units in 1894, equivalent to 200,490,000 gallons.

Detection of Waste.—The whole of the 76 miles of mains in London are, as a rule, in communication with one another; but certain valves are kept closed in such a way that the several main circuits are in communication with one another at the central station only. The superintendent at the central station has it then in his power at any time to divide the supply into four distinct sections, and by observation of the pressure gauges it can readily be ascertained through which section an abnormal flow is occurring. The main in which this abnormal flow is proceeding has then to be shut down at intervals, till at last the leak is run to earth. At the pressure of 750lb. per square inch 3,000 gallons per hour would pass through an orifice of only $\frac{1}{16}$in. diameter, which shows how small in reality the leakage from the mains must be. The principal source of waste is undoubtedly on the consumers' premises.

Frost.—The severe and prolonged frost of last winter did not seriously affect the supply. About 1,150,000 gallons was pumped to waste during Sundays in order to maintain the circulation; but after allowing for this 91·65 per cent. of the total water pumped was registered. This fact alone is conclusive; but in a few places sub-mains in exposed positions were frozen, though in nearly every case they were quickly cleared. No consumer, it is believed, was seriously inconvenienced. The frost was down in the ground quite 3ft. in places, and there were five or six instances of broken mains. The damage done was greater than on any previous occasion. The surface of the roads was so hard that the water could not get through the paving, and in two or three places found its way into cellars. In two instances the water was forced between the concrete and the wood paving, floating the latter, and at last finding a vent about 100 yards away from the break. It was not found necessary to relay the pavement thus lifted, except in a few places, for it settled down all right again after the water had run off. There were other novel experiences of the severity of the weather. In the Thames Embankment subways there were several degrees of frost, and during its continuance, in order to reduce the risk, the area of supply was divided into sections, and the embankment main had thus a dead end; the temperature fell, the main contracted, a large number of the joints opened, and huge icicles formed round the flanges. As soon as this was discovered, the valve shutting off the City was opened, the water which is sent into the mains at 60deg. flowed through and thawed the pipes that had contracted, and most of the joints again became quite sound. In connection with this question of warming the water, it is interesting to note that the water pumped from the river was below freezing point. The water is heated by passing it through the surface condensers of the engines; but at the new stations, where the triple-expansion engines are used, it was found that the temperature could not be raised much above 40deg. in the filtered-water tanks, and in order to maintain the water at the higher temperature of 60deg. it was necessary to destroy the vacuum in the condenser, thereby rendering the engine less economical for the time being. Another experience my be mentioned in connection with low temperatures which shows that high apparent economy is not always real economy. At the Wapping and City-road stations the economisers are arranged much in the same way as for the Glasgow works. The temperature of the gases leaving the economisers was reduced to 238deg. or 240deg., and the temperature of the hot-well condensed water entering the economiser was 65deg. or 70deg. The consequence has been that it has been found necessary to renew the economiser tubes after three years' work, owing to the condensation on the outside of the tubes and their consequent corrosion. The cost of the renewal is larger than the saving of fuel effected. Arrangements are now being made to obtain a higher hot-well temperature.

Application of Power.—Hydraulic power has to be supplied under competition with steam, gas, and electricity, and the success which has attended its introduction shows conclusively that it is well able

Digitized by Google

to meet this competition for lifting and for other intermittent work. None of the supply systems which have been established have aimed at meeting the demand for continuously running motors, except in Antwerp, where the supply has been laid out as a means for generating electricity for lighting. At first sight it is somewhat difficult to see how this can be an economical mode of employment. There are, however, a few places in London where the hydraulic power is used to generate electric current. The apparatus consists of a Pelton wheel, with the armatures of the dynamo mounted on the same shaft. The following are the particulars of a trial made with this apparatus at the hydraulic engineering works at Chester in October, 1894: Pelton wheel, 18in. diameter, 54 buckets; Elwell-Parker shunt-wound dynamo for charging accumulators, having a commercial efficiency of 87 per cent. as tested by the makers; speed, 1,671 revolutions per minute; bore of nozzle, 0·175in.; hydraulic pressure, 725lb. per square inch; output 37½ amperes at 120 volts; water consumption, 20 gallons per minute; power in water 10·15 H.P., in output 5·99 H.P.; efficiency, 59 per cent. This is not the highest efficiency that could be obtained, for the wheel and dynamo were not perfectly adapted to each other. External resistance had to be used for keeping down the voltage, and at this output the dynamo was somewhat overworked. In a previous trial, with 0·16in. nozzle and an output of 26 amperes at 122 volts, the efficiency was 59·86 per cent. It is unlikely, however, that even under more favourable conditions the conversion can be effected with a greater efficiency than 66 per cent.

Comparison of Hydraulic and Electric Power Supply.—It is interesting, therefore, to inquire whether there are any grounds for the assumption that hydraulic power obtained otherwise than from a natural head of water can be used economically for generating an electric current. It so happens that the materials are available for a comparison between the cost of a public supply of hydraulic power and that of electricity obtained from a central station on almost exactly the same scale. The particulars given in Table II. are taken from the records of the London Hydraulic Power Company and of the Westminster Electric Supply Corporation for the year ending December 31, 1894. In making the comparison, 1,000 gallons of water at 750lb. per square inch is taken as equivalent to 6·518 Board of Trade units of electricity. This analysis shows that the station cost of the hydraulic power is 5·172d. per thousand gallons pumped at the pressure of 750lb. per square inch; while the corresponding cost of an equivalent amount of electric energy reduced to the same hydraulic standard is 9·014d. per 1,000 gallons; or on the electrical standard of Board of Trade units, 0·793d. and 1·383d. respectively. The output during the year, the capital employed, and the average rate received for both supplies, are nearly the same. The coincidence of the figures is extraordinary, except in the cost items, in which their divergence is equally remarkable. No other conclusion can be drawn than that for some reason or other not hitherto explained hydraulic power is much less costly to produce than electricity. The Westminster electric supply is one of the largest in the country, and its cost is one of the lowest. The London hydraulic supply is the greatest anywhere, and is produced, no doubt, very cheaply. In neither, however, has the minimum cost been reached, for in both of them the station cost in the newer installations is considerably below the average for 1894. For instance, the station cost of the hydraulic power supply from the Wapping station for 1894 was only 4·177d., as against 5·172d. for the whole supply, while the station cost of the Davies-street station of the Westminster electric supply is equivalent to 8·731d. per 1,000 gallons, as against 9·014d. for the whole supply. It may be thought that the low annual load factor of, say, 0·18 for the electrical supply, as against 0·33 for the hydraulic, accounts for most of the difference; but under the able control of Prof. Kennedy the influence of a low load factor has been to a great extent neutralised by running the machinery actually in use at nearly full load. Moreover, the figures of other electric installations, such as the St. James's and Pall Mall, where the load factor is much higher than in the Westminster district, show a similar difference of cost as compared with the hydraulic supply. Now it is obvious from the figures of the London and Westminster installations that, as the output during the year was the same, while there is so great a difference in the annual load factor, the maximum horse-power employed is much greater for the electric than for the hydraulic supply; but the output per unit of capital outlay seems to be much the same. This is no doubt owing to the greater concentration of demand in the area supplied with electricity. If a large amount of power is concentrated in a single station, it is practicable to work that station much nearer to its maximum capacity than if the same power had to supplied from two or three stations. In the London hydraulic supply, while the annual load factor is 0·33, calculated on the maximum delivery at any time during the year, the load factor of the whole plant in use during the year under the most favourable conditions is only 0·20, and is often much lower; in other words, more than one-third of the whole plant is always in reserve, and in some years as much as half. The proportion of plant out of use altogether, or not running at full load at the periods of maximum demand, is no doubt much less at most electric lighting stations, and the load factors of the two systems calculated upon the total station plant probably do not differ widely. The fact that the load factor calculated on the maximum flow is lower for the electric supply than for the hydraulic does not, other things being equal, account for the larger part of the difference of cost. This is shown also by a comparison of the cost of the hydraulic supply during a week when the output is large and during another when it is small. During the week ending October 18, 1894, altogether 9,095,000 gallons were pumped at the London hydraulic power stations, and during the week ending December 27th 5,902,000 gallons only. The increased cost for fuel in the latter week was 0·317d. per 1,000 gallons, and for wages 0·77d. per 1,000 gallons, making 1·087d. per 1,000 gallons, whereas the average excess cost of the electric supply is more than 3½ times as much, and in the item of coal nearly five times as much. The immediate question, however, is the economy of using hydraulic power for generating electricity, and it will be seen from the foregoing figures that, with a loss of 33 per cent. of the hydraulic energy during conversion into electric energy, the station cost of 0·793d. per Board of Trade unit would rise to 1·189d., or 0.194d. below the cost 1·383d. of the direct current of the Westminster supply.

Table III.—*Antwerp Hydraulic Power Service.*

1895.	January to April. 4 months.	January. Maximum month.	April. Minimum month.
	Gallons.	Gallons.	Gallons.
Quantity pumped	59,080,000	20,178,000	11,772,000
Station cost per 1,000 gallons.	Pence.	Pence.	Pence.
Coal	2·618	2·483	2·614
Engine-room stores........................	0·118	0·130	0·134
Wages	0·693	0·512	0·840
Total	3·429	3·125	3·588

The cost will be further increased by the wages, superintendence, and repairs at the converting stations, so that on the whole there does not seem much probability of any economy resulting from this method of generating electricity on a large scale. It may be mentioned that the principal reason which led the late Prof. Van Rysselberghe to advise the combined method for the electric supply of Antwerp was that he considered the losses of distribution of the electric current would be much less on that method. The losses of distribution, however, are not very serious either way, and the direct or the combined method must ultimately stand or fall, the author considers, on the relative generating cost per unit. Mr. L. Moris has kindly furnished the particulars in Table III. of the working of the Antwerp hydraulic service. The very low cost per 1,000 gallons pumped is evidently due to the small amount of wages paid at the central station, and the figures include nothing for superintendence, water supply, lighting of station, removal of ashes, or repairs to machinery. At least 1½d. per thousand gallons should be added for these items in order to make the cost comparable with that of the London stations. It will be noticed that the reduced output in April increased the cost only 0·46d. per thousand gallons, or, say, 15 per cent., while the output was only 58 per cent. of that in January. It seems, however, that notwithstanding the low cost at which the hydraulic supply is obtained in Antwerp, the general results of the combined method during the first nine months of working have not been satisfactory. It is stated that the arrangements have proved more costly than the usual direct method, not only in first cost, but in working expenses. The capital outlay per electric unit would probably be greater, but there seems no sufficient reason why the working expenses should be increased. Further information is required before an explanation can be given. While the combined method does not seem to have any sufficient basis for a general system of distribution, it is evident from the foregoing figures that electricity can be economically generated by means of hydraulic power artificially obtained; and the latter can, therefore, be used with advantage as a supplement to ordinary methods of generating electrical energy. Hydraulic power is clearly much the most economical in those applications where the direct pressure can be utilised—such as for lifting and pressing. Where rotary motion is needed, the special circumstances of each case will determine what power shall be used, and all are now more nearly on a par as regards cost. For motors running regularly for several hours a day the London hydraulic power stations now supply power at a rate of 1s. 6d. per 1,000 gallons, which is equivalent to 2·76d. per Board of Trade unit of electricity, or, say, 3d. per brake horse-power per hour. It is questionable whether small powers can by any means be obtained at a lower rate when all the items of cost are taken into account.

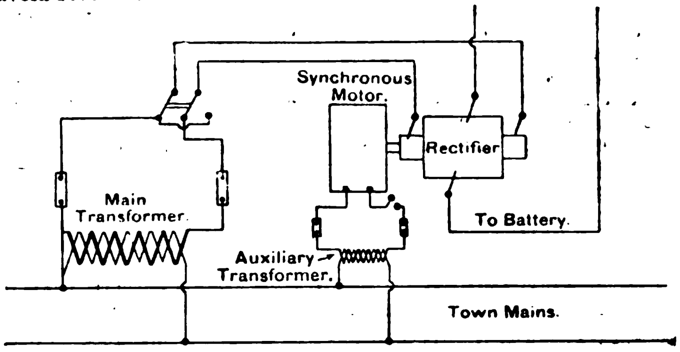
CHARGING ACCUMULATORS BY ALTERNATING CURRENTS.

An account is given in a recent number of the *Zeitschrift für Electrochemie* of a method suggested by Herr C. Pollak for charging accumulators by means of rectified alternating currents.

The requisite apparatus for converting an alternating current of high voltage into a uni-directional current of low voltage consists of a main step-down transformer and a small auxiliary transformer, which drives a synchronous motor, having a commutator on a prolongation of its spindle, to which current is led and from which it is taken, after rectification, by appropriate brushes. The whole arrangement is clearly shown in the accompanying figure. By adjusting the set of the brushes the flow of current to the accumulators can be stopped at such part of each alternation as to avoid reversal.



At the Pollak Works at Frankfort the town supply of current at a pressure of 3,000 volts is transformed down to 65 volts and rectified as described above, the resulting uni-directional current serving for general electrolytic purposes as well as for driving ordinary direct-current motors. An efficiency of 96 per cent. is claimed for the rectifier, 2 per cent. loss being encountered in driving the small synchronous motor, and 2 per cent. in contact resistance.

ELECTRIC POWER IN FACTORIES AND MILLS.*

BY F. B. CROCKER, V. M. BENEDIKT AND A. F. ORMSBEE.

Introduction.

The application of electric power distribution to the operation of factories and mills, including the driving of the various machines and other apparatus, is the latest and one of the most important problems toward which attention is now being directed, the question being one of extreme prominence both from an economical as well as from an engineering standpoint. In comparing two or more different systems of power distribution, the fundamental basis of comparison is generally that of dollars and cents. This is certainly correct, as far as it goes; but unless a very decided difference be found between the costs of running under the various systems, it may be found that other factors enter ; factors which cannot be estimated in dollars and cents—namely, questions of desirability and convenience. Without considering any tests whatever, there are several exceedingly advantageous points in the use of motors in factories which are almost self-evident, such as: 1. Clear and unobstructed passages and head room, the latter facilitating the use of travelling cranes. 2. Ease of shifting the tools from place to place, possibly necessitating the placing of a starting box and the putting up of a little extra wire, as compared with the inconvenience and trouble of setting up and adjusting a line of shafting, hangers, belts, &c. 3. The economy due to the ability to run a single tool without necessarily starting the whole factory or at least a complete section. 4. The running expense is entirely stopped when the tool is shut down. 5. The absence of the drip of oil from overhead shafting. 6. The tools may be placed at any desired points almost regardless of the distance. 7. It is not necessary to arrange the tools parallel as in the mechanical system. 8. A wider range of speed is possible. 9. Less damage caused by a fuse blowing than by a belt slipping off in case of accident or excessive load. Considerations like the above have great weight in deciding a question such as that under discussion, and there is no doubt whatever that in most cases they rise to such prominence that they warrant a complete change from the old system to the new, even though there is no gain in economy or increased output. In most cases, however, it has been conclusively shown that considerable saving and increase in production is obtained, one test showing a very considerable percentage of increase in the output.

* Paper read before the American Institute of Electrical Engineers at Niagara Falls.

The partial, if not the complete, displacement of the old method by the new is only a question of time, and it was the appreciation of this fact that induced the authors to undertake the determination of the power actually required to run the various tools and machines as used in ordinary practice.

Historical Notes.

The subject is a comparatively new one, not dating back further than about 1890; hence the history of the subject is necessarily short. About five years ago motors were in operation in the works of the Thomson-Houston Company at Lynn, the Crocker-Wheeler Company and the C. and C. Company. Shortly afterward the great German works of the Siemens and Halske Company and the Allgemeine Elektricitäts Gesellschaft began using motors to operate sections of their factories. From that time to the present the use of motors has extended rapidly, until now they have been adopted in many factories all over this country and to a less extent abroad.

Practical Tests.

In the tests which follow, the power required to drive the tools was obtained by placing an ammeter in the circuit of the motors running the various machines and groups of machines, and taking readings every few seconds, the frequency of the readings depending upon the nature of the tool and the work it was doing. The potential was practically constant at 110 volts, not varying more than 1 or 2 per cent. The first tests were made at the factory of the Crocker-Wheeler Electric Company, at Ampère, N.J., and the machines tested and the results obtained were as follows :—

1. *Large Boring Machine.*—This machine was driven by a 1½ H.P. motor, speed 1,200 revolutions per minute, mounted directly on the frame of the tool, the reduction in speed being obtained by the use of gearing. During this test, which lasted three hours, the machine was used for turning down a commutator for a 100 H.P. dynamo. The average current drawn was 8·3 amperes, representing 1·23 H.P. at 110 volts. Before the run was finished, the speed of the tool was increased by changing the combination of gears, and during this time the power required was 1·43 H.P. When the machine was started from rest, the rush of current was considerable, the average being 17·75 amperes, representing 2·6 H.P. It will be seen that this motor is well suited to the machine, the average load being very close to the rated power of the motor.

2. *Drill Press.*—A drill press was run by a 1 H.P. motor, speed 545 revolutions per minute, mounted on a shelf at top of press and belted down to countershaft at bottom and thence up again to main shaft of machine, thus securing a reduction of the speed. This machine was boring the faces of the cast-steel pole-pieces of a 10 H.P. motor, two cutting tools being used. The test lasted 4 hours and 40 minutes, and during this time the pole-pieces for three motors were bored. The first run covered 1 hour and 10 minutes, and the average current was 2·92 amperes, representing 0·43 H.P. It required 15 minutes to replace the completed pole-piece by another one. This second piece required 2 hours and 32 minutes to finish, and the average amperes was 2·82 or 0·41 H.P. This time it required 17 minutes to replace the piece, and then the machine ran only 23 minutes until closing time. The current for this short run was 2·81 amperes, representing 0·41 H.P. The total length of time the machine was running was 4 hours and 5 minutes. Therefore power was supplied to the motor 86 per cent. of the time of the test.

3. *Drill Press.*—This machine was similar to the one preceding, but the work was different—namely, drilling half-inch holes in cast-iron bearings. The average current was 2·86 amperes, which represents 0·42 H.P.

4. *Drill Press.*—This tool was the same as the other two, and the work consisted in boring the inside of cast-iron bearings. The average in this case was 1·9 amperes, or 0·28 H.P. It will be noticed that in the case of these three machines a motor of ½ H.P. would be of ample size to do the work.

5. *Punch Press.*—This was a small punch run by a 1 H.P. motor, mounted on the base of the machine and belted to its heavy fly-wheel. The speed of the motor was 700 revolutions per minute. This tool was punching slots in sheet iron discs for a 10 H.P. armature, there being 28 slots in each disc. The motor was turned off every time a disc was replaced, but it did not come to a dead stop, as the inertia of the flywheel was so great. Readings were taken every five seconds, and the time of turning on and off the current was noted. The test lasted 57 minutes, during which time the current was turned on for 35 minutes and 45 seconds, or 62·7 per cent. of the time. The average current was 4·86 amperes, equivalent to 0·71 H.P. The rush of current at starting varied from 7 to 15 amperes, depending upon the haste of the workman in turning on the starting box.

6. *Gang Drill.*—This tool was driven by a 1 H.P. motor, 1,000 revolutions per minute, mounted with vertical shaft in frame of the machine and belted directly to the three drill spindles. The material drilled was cast-iron, and the sizes of the holes were ¼in. and ⅜in. The average of the readings taken was 4·75 amperes or

Digitized by Google

0·7 H.P. When the drills were running free the motor took 3 5 amperes. Thus the power required to overcome friction was 74 per cent. of the power used while drilling.

7. *Group of Two Machines, One Lathe and One Milling Machine.*—This group was driven by a 3 H.P. motor, belted to a short line shaft, from which belts ran to the countershafts above the two machines. The average current was 10·04 amperes, the power being 1·48 H.P. In this test special attention was paid as to which machine happened to be running free, cutting, &c., with the results given in the following table :—

Class of machines and work.	Amperes.	H.P.
Milling machine running free—lathe at rest	5·67	0·836
Lathe „ „ „ —miller „	7·36	1·085
Both running free	10·0	1·47
Milling machine cutting—lathe run free	10·33	1·52
Lathe cutting—milling tool running free............	14·42	2·12
Both tools cutting	15·4	2·28
Cutting rate increased on the lathe	17·8	2·61

8. *Group of Six Machines, consisting of 1 Milling Machine (small), 2 Lathes (10in. or 12in. swing), 1 Grindstone, 1 Drill Press, and 1 Small Punch Press.*—The last-named tool was not run at all during the test, and the grindstone ran continuously. This group was run by a 1 H.P. motor, belted to the usual ceiling line shaft. The average current required to drive these machines was 5·86 amperes, representing 0 86 H.P. Thus this motor ran at about its most economical load.

9. *Group of Seven Machines: 1 Planer (small), 1 Grindstone, 4 Lathes, 1 Hand-Turning Lathe.*—A 3 H.P. motor was used to drive this group, being belted to a line shaft, the same as the previous groups. The current was 13 36 amperes, or 1·97 H.P. When the entire group was in use 2 65 H P. were required.

10. *Group of 7 Lathes and 1 Grindstone, driven by a 3 H.P. Motor.*—The average current was 9·92 amperes, and the power required was therefore 1·46 H.P. The power used by the motor when different numbers of lathes were running is shown by the following table :—

Number of lathes running.	Amperes.	H.P.
One	7·76	1·14
Two	9·16	1·35
Three..	10·69	1·58
Four	12·23	1·8

Thus, in a group like this, it only takes 63 per cent. more power to drive four lathes than it does to run one, the reason being the fact that it probably takes about 1 H.P. to drive the countershafts.

11. *Group of Two Machines, a Large Punch Press, and a Large Planer.*—The motor for running this group was placed on the floor, and drove a short line shaft on the ceiling by the usual form of belt. The rated capacity of this motor was 7½ H P., and its speed was 1,350 revolutions per minute. The punch press did not run during the test. With the planer idle, and the motor driving the shafting and belting alone, the current was 15 5 amperes, which represent 2 3 H.P. While the planer was at work the motor required 33·1 amperes, or 4·87 H.P. As the loss from friction in the shafting is nearly constant under the variation of load, the power required to overcome this friction was 47 per cent. of the total power used. When the bed of the planer reversed from its slow cutting stroke to the comparatively rapid return stroke the current increased to 52 amperes, showing an expenditure of 7·6 H.P. for a few seconds. This tool was planing the frame of a 90-kilowatt multipolar dynamo, the material being cast iron.

12. This group was a very large one, consisting of 20 machines, 8 lathes, 4 milling machines, 3 planers and sharpers, 2 grindstones, 1 vertical shaft grinding machine, and 3 small tools. The motor in this case was rated at 10 H.P. at 750 revolutions per minute. A Thomson recording wattmeter was placed in the circuit of this motor for one afternoon. At the end of this time the wattmeter showed a total of 17,854 watt-hours used, and as the time was five hours, the average power was 3,571 watts, or 4 78 H.P. The average number of machines running was 13, most of the lathes being in use the greater part of the time. An ammeter was inserted in the circuit of the motor for a few minutes, and it was noted that the work was very steady, the current not varying more than 3 or 4 amperes at any time.

13. A group of five machines run by a 3 H.P. motor was next tested. Of these five machines, one was a lathe with 17in. swing and 8ft. bed, one was a slotter, and the other three were lathes of 12in. or 14in. swing. The average amperes were 7, and the power 1·03 H.P.

14. The last tool tested at this factory was a large new engine lathe, which had just been set up, of 50in. swing. This tool was driven by a 3 H P. motor mounted on an iron bracket built in the base of the machine. The motion of the motor shaft is transmitted to the tool by gears, thus doing away with all belts. The work done was turning a 5½in. steel shaft for a 200-kilowatt dynamo, facing the ends, &c., the cut being very light, as the work was only preliminary. The average current consumption was 11·4 amperes. Hence the average power was 1·68 H.P.

The following tests were made in the erecting shop of the De La Vergne Refrigerating Machine Company, at Port Morris, N.Y. :—

1. *Planer.*—A large planer, 120in. between posts, by 108in. high, by 22ft. bed, was driven by a C. and C. motor of 15 H.P. The voltage employed was supposed to be 220, but due to an incorrect station voltmeter the actual potential only averaged 190 volts on the morning of this test. The average current was found to be 20 08 amperes, which at 190 volts represents 5·11 H.P. At the reversal from the cutting to the back stroke the current increased to 85 amperes, equivalent to 21·65 H.P. The power required during the cutting stroke was 4·76 H.P., while on the return stroke the average was 5·73 H.P.

2. *Drill Press.*—A drill press driven by a 5 H.P. C. and C. motor was tested in the afternoon. The potential was raised before this test so that the average was 215 volts. The power required when drilling various size holes is shown in the following table :—

Size of drill.	Amperes.	H.P.
Running free.	3·0	0·865
⅞in.	4·07	1 23
$\frac{21}{32}$in.	4·37	1 26
$\frac{31}{32}$in.	4·6	1·33

3. *Corliss Cylinder Boring Machine.*—This tool was driven by a 10 H.P. C. and C. motor and was boring the brass boxes, 6¾in. diameter, of the main shaft bearing of a large ice machine. The average current was 14·47 amperes, representing 4·17 H P. at 215 volts.

In order to place the results in a more convenient form the following table of average powers was compiled :—

Tests at the Crocker-Wheeler Factory.

No. of test.	Size of motor.	Number of tools driven by motor.	Average amperes.	Average H.P.	Remarks.
	H.P.				
1	1·5	1 boring machine.	8·3	1·23	
2	1·0	1 drill press.	2·85	0·42	Less than half full load of motor.
3	1·0	1 „	2·86	0·42	
4	1·0	1 „	1·9	0·28	
5	1·0	1 punch press.	4·86	0·71	
6	1·0	1 gang drill.	4·75	0·7	Drilling ¼in. and ⅜in. holes.
7	3·0	2 machines.	10·04	1·48	
8	1·0	6 „	5·86	0·86	All small machines.
9	3·0	7 „	13·36	1·97	
10	3·0	8 „	9·92	1·46	
11	7·5	2 „	33·1	4·87	Required 2·3 H.P. to run shafting only.
12	10·0	20 „	...	4·78	Tested by wattmeter.
13	3·0	5 „	7·0	1·03	
14	3·0	1 engine lathe.	11·4	1·68	Light cut taken by tool.

Tests at the De La Vergne Works.

No. of test.	Size of motor.	Number of tools driven by motor.	Average amperes.	Average H.P.	Remarks.
	H.P.				
1	15·0	1 planer.	20·08	5·11	Planer 10in. × 9in. × 22in. Voltage 190. ⅞in. drill.
2	5·0	1 drill press.	4·07	1·23	Voltage 215.
3	10·0	1 boring tool.	14·47	4·17	Voltage 215.

The results obtained in these tests show that the power required to drive machine tools has been considerably over-estimated, for it will be noted that with a large majority of the tools tested, the motor was not more than one-half loaded, and in these cases it was seldom that the load equalled the full power of the motor, even for an instant. In the case of the large planer, although the motor was overloaded 50 per cent. upon reversal of the bed, the average load was only one-third of the rated full load. With this machine, however, when the piece of work is very short, necessitating more rapid reversals, the average load will be much nearer the most economical output of the motor.

The question of running machine tools by individual motors or grouping a number of machines together and driving them by one motor, does not seem to allow of a general solution. It would not be advisable, for example, to use the individual system where there are a number of small tools, each one of which requires only a small fraction of a horse-power. On the other hand, if we have a large tool that requires considerable power, it would seem to be far more economical to run it by a single motor, using as little belting and shafting as possible.

Digitized by Google

Many of the manufacturers of machinery are now supplying boring mills, punching presses, drill presses and other machine tools arranged to be driven by electric motors. In most cases all that is necessary is a shelf or bracket on the tool to support the motor, and a gear wheel in place of the main pulley, unless a belt connection is preferable. A press or other tool having a large fly-wheel may be driven very conveniently by cutting teeth on the edge of the wheel which gear with a pinion on the motor shaft.

Electric Power in the New England Cotton Mills.

The introduction of the electric system of distribution of power in the cotton industries of New England is now fairly begun. Although there are no large mills driven entirely by this system, a number of them have an electric plant and certain sections of the mill are driven by motors. An electric plant was installed four or five years ago in the works of Silver Spring Bleaching and Dyeing Company, at Providence, R. I., but it was intended chiefly for lighting. But motors were placed in the carpenter and repair shops, and several other places, until at present there are about 100 H.P. of motors installed in eight units. The generating plant consists of three 100 H.P. U. S. dynamos belted together from a countershaft which is driven by a Corliss engine. Two of the machines are 110-volt dynamos, which are used for lighting and running most of the motors at present. The third machine which has just been installed is a 500-volt Westinghouse power generator of the same type as the lighting machines. There is only one machine at present connected to the 500-volt circuit, a 30 H.P. motor which drives a centrifugal pump supplying a storage reservoir with water for use in the bleacheries. The electric plant in this mill is not of much importance yet, but its chances for development are very bright, since there are a number of machines now run by individual steam engines. These could be most advantageously replaced by electric motors, as they are in some cases a great distance from the boilers, involving large losses from condensation.

A visit was made to the works of the Donnell Manufacturing Company, at Pawtucket, R.I., where a very fine electric plant has very recently been installed to drive the calico printing machines. The problem of running this class of machinery by electric motors has been a very difficult one to solve, for the motor must be capable of running at a number of different speeds and running constantly at any given speed with a variable load. In this case it has been solved by the use of a modification of the Leonard system of motor regulation. The outfit for each printing machine consists of a motor and a dynamo of the same size, the field rheostat of the dynamo being placed alongside the printing machine. The speed of the motor is thus changed by varying the voltage of the particular dynamo which supplies it with currents.

The dynamo room contains eleven dynamos of the new moderate speed, four-pole type, made by the General Electric Company. They are run by a Corliss engine through a system of belting and ceiling countershafting. Six of these are 20-kilowatt machines and four are 25 kilowatt. The eleventh dynamo is a similar 20-kilowatt machine used for exciting the fields of the other dynamos. The normal potential is 250 volts, and is lowered in any particular dynamo when slower speed of the motor connected to that circuit is desired. This plant has been completed but a short time, and it was not possible to obtain any accurate figures showing the power used by the motors under various conditions of speed and load. Formerly the machines were run by individual engines, and much difficulty was experienced in starting them, as the pressure of the printing rolls against the cloth is so great. With electric motors this difficulty is overcome, as the motors will stand a very heavy overload for a short time, and the starting torque is very great. The great advantage of the electric system as here used is not so much in the saving of power as in the convenience to the workmen, and hence the increased production. The saving of power, however, is quite considerable, as in the old system steam was piped several hundred feet to the small individual engines, which were necessarily inefficient under the best conditions, and added to this the engines were run part of the time with partly closed throttle, still further decreasing the efficiency. With the present system the attendant at the machine may quickly vary the speed any amount by turning the rheostat near the machine. Although this plant has been in operation only a short time, it is claimed by those in control that the production is materially increased. In a Paper by Mr. S. B. Paine in *Power*, June, 1895, he states that the increase in the production amounted to more than 25 per cent., and that the quantity of "seconds" (inferior product) was also considerably reduced. This is very important, as the men in charge of printing machines are skilled workmen of the higher order, and a small saving in wages for a given production is of more value than a considerable saving of power.

A visit to Baltic and Taftville was also made to see the practical working of the well-known power transmission plant between these places. At Taftville, where the Ponemah mills are located, there is not sufficient water power to drive all the machinery, so an electric plant was installed at Baltic, 4½ miles up the river, where a dam had been built, giving an available head of 34ft. The wheels are horizontal balanced turbines, two of them being rated at 800 H.P. each, while the third one is rated at 300 H.P. The wheels are belted to a long line shaft, which is in turn belted to the dynamos. The generators, of which there are two, are placed in a separate room. They are of the three-phase General Electric type and are capable of supplying 250 kilowatt at 2,400 volts. They have ten poles and run at 600 revolutions per minute, giving a frequency of 50 cycles per second. The field is excited by a 3 kilowatt bipolar dynamo belted from the generator shaft. The power is transmitted to Taftville by a very well constructed pole line. The motors are located in the basement of the Ponemah mill near the engines which they replace. They are belted to pulleys which are connected to their respective shafts by friction clutches in order to enable the motors to be started without load, as they are of the synchronous type. The motors are identical with the dynamos, except in having an induction winding of heavy bars sunk in the pole-pieces, to cause them to be self-starting. In starting the motors, the switch in the induction circuit is closed and then the line is connected to the armature, causing it to start as an induction motor, without a very great torque, however. When the motor has nearly reached full speed the field is excited and it will speed up until it falls into step, and then the induction switch is opened. This method of starting has two advantages: first, no auxiliary motor is needed; second, no device is required to tell when the motor is in synchronosm with the generator.

One of these motors drives 1,200 looms, requiring an expenditure of about 155 H.P. The other drives 500 looms and also the railway generators for the Norwich Electric Railway Company. The introduction of this plant has enabled the Company to concentrate all its power for use in one mill, tending to decrease the cost of production, diminishing transportation charges, and avoiding the use of any coal for steam power.

Conclusions.

First Cost.—Practically the only objection which can be urged against the electric system is the fact that the first cost of installation is greater than with ordinary belting and shafting, but even this is questionable, since the authors know of cases in which the estimated total cost of installing the necessary belting and shafting was actually greater than the equivalent electric motor outfit. The electric system would be cheaper, for example, in the case of very long or scattered buildings or those containing many stories or rooms, in any of which cases the belting and shafting required would be very complicated and expensive. The use of belting and shafting requires a much stronger and more expensive roof or ceiling than the electric system.

Saving of Power.—It might seem that the electric system would actually consume more power than the ordinary plan, since it involves two transformations of energy. In most cases, however, if the power has to be distributed to a number of machines, particularly if they are located at any distance from the engine, the loss of power is less with electric transmission. This is explained by the high efficiency of the dynamo and motor compared with the low efficiency of belt transmission as ordinarily practised, involving as it often does very imperfect alignment and lubrication of the shafting. Perhaps the greatest saving, however, of the electric system is due to the fact that the consumption of energy entirely ceases when the tool stops. This stoppage in the case of the busiest tools amounts to at least 25 per cent. of the nominal working hours throughout the year, and with large or special tools which are not used so steadily the stoppage is often as high as 50 to 75 per cent., since there are many whole days when they are not used at all.

Idleness due to strikes as well as to slack times must also be considered, and would usually amount to quite a large percentage in 10 years, for example. This assumes, of course, that a portion of the shop is running, which is usually the case even under such conditions. In short, with the mechanical system there is an enormous amount of shafting, idle pulleys and belting which runs for long periods of time doing little or no useful work, but consuming considerable power. Wherever electric motors can be substituted for a number of small engines scattered about, the saving in power is very great, not only because of the low efficiency of small steam engines, but also by the avoidance of condensation in long steam pipes.

Increased Output.—This is, perhaps, the most important advantage gained by the electric system, since after all the cost of power is a very small item, being, according to Mr. Richmond,* only about 1 per cent. of the wages paid in average machine-shop practice. This increased output is secured by the greater convenience and promptness in starting and stopping, as well as in regulating the speed of the machinery. The workman can, for example, temporarily increase the speed when the conditions are favourable, thereby saving considerable time.

Flexibility.—The great convenience of moving the tools and placing them in any desired position is another great advantage of the new system. The great adaptability of this system is par-

* *Engineering Magazine*, January, 1895.

Digitized by Google

ticularly well shown in the case of a factory which was almost completely destroyed by fire; nevertheless, a few uninjured tools in a remote end of the building were operated successfully by means of electric motors within two days after the fire.

Speed Regulation.—The ordinary type of motor used in factories is the plain shunt-wound machine, fed with constant-potential current. The motor is started, and varied in speed by means of a rheostat in the armature circuit. This simple arrangement answers very well in most cases, but for variable speed between wide limits a series-wound motor controlled by a rheostat, as in electric railway practice, may be preferable. In other cases some special method of regulation, such as the Leonard system or the "boost and retard" plan, may be adopted.

In concluding, the authors wish to express their sincerest thanks to the various companies for the courtesy shown by them, and for the kind assistance which they rendered during the tests.

AN APPARATUS FOR MEASURING DIFFERENCE OF PHASE BETWEEN ALTERNATING CURRENTS.*

BY LOUIS DERR.

Most of the methods hitherto employed for the measurement of difference of phase between alternating currents (*vide La Lumière Electrique*, March 10 and 17, 1894) assume that the currents measured are truly sinusoidal in character, or demand exceptional conditions of steadiness. The method here described is applicable to the measurement of periodic currents of any form whatever, and can be used under ordinary conditions. The apparatus is a modification of that employed by Dr. J. Puluj for a similar purpose, and described at length in the *Elektrotechnische Zeitschrift* for December 1, 1893. Dr. Puluj's apparatus consists in brief of a pair of electro-magnets, each carrying a flat steel spring at the free end of its core, a small mirror being mounted on the spring. A beam of light is reflected from one mirror upon the other, and thence to a screen. If alternating currents are sent through the magnet coils the springs will be set vibrating, and the spot of light on the screen will be lengthened into a line if the springs are parallel; and if the springs be turned so that the vibrations are perpendicular to each other, the line becomes an ellipse whose dimensions afford a measure of the difference of phase between the currents in the coils. It is evident that to maintain an ellipse sufficiently stable to permit measurements of precision requires great steadiness in the currents, a condition not always obtainable. The springs give best results when their period of free vibration is that of the current or its octave, and slight changes of the current period will throw them out of tune, instantly affecting the amplitude of vibration, as the inertia of the moving parts is very small. Belt slip at the generator, irregular load or changes of steam pressure, make precise measurements very difficult.

To obtain results without the steadiness demanded by the above method, the following modification was devised by the writer, and successfully used by Messrs. L. R. Nash and J. C. Nowell, of the class of 1894, in their thesis. The two electro-magnets were placed side by side, and the beams reflected from their mirrors received upon a prismatic mirror, and thence sent to the screen. This is shown in plan in Fig. 1. In this case the spots of light which appear on the screen when the mirrors are at rest are elongated into two vertical lines when currents are sent through the magnets, and these lines are drawn out into curves which flash across the screen when the prismatic mirror is rotated. As the motion of the springs is harmonic, these curves are sine curves, and thus bear no necessary resemblance to the original wave form.

* Abstract from *Technology Quarterly*.

The theory of measurements is as follows: If the spots of light on the screen are in the same vertical line when the prismatic mirror is at rest, the curves produced by revolving it will have the same time origin, and will be parallel if they are in the same phase. Any time lag of one behind the other will be shown by a lateral shifting of the lagging curve ahead of the other, and if a variable inductance is inserted in the circuit of B, the B curve will be seen to move farther and farther ahead of the A curve as the inductance is increased. The difference of phase is thus evident to the eye, and to obtain a direct measure of it requires only a knowledge of the angle through which one curve must be shifted to bring it into parallelism with the other. This is readily expressible in degrees by finding the angle through which B must be turned to bring E and F (Fig. 2) into the same vertical, and then finding the angle through which B must be further turned to bring G and E into the same vertical, the first adjustment giving the portion of a wave length by which the two curves are separated, and the second

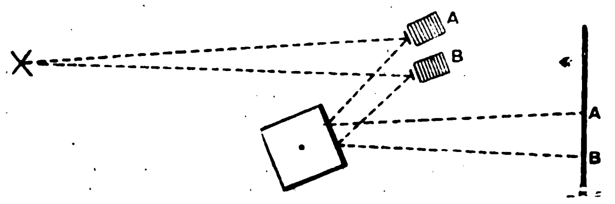

FIG. 1.

the value of the whole wave length. Calling these quantities c and d respectively, the phase difference of the curves on the screen is, in degrees, $360c/d$. One consideration is to be noted here, that as the vibrating springs execute a complete vibration for every reversal of the current, their vibration frequency is just twice that of the current, and hence the phase difference of the curves on the screen is twice that of the currents measured. The desired value is thus $180c/d$.

As c and d are too small to be directly measured with precision, a multiplying device is necessary. Mirror B is turned by a gear wheel meshing with a small pinion which carries a long pointer moving over a divided scale. With this device a wave length on the screen is covered by a displacement of 13cm. of the end of the pointer.

The procedure is as follows: With the prismatic mirror at rest, send the currents to be studied through A and B respectively. Turn B until the lines on the screen are in the same vertical, and take the pointer reading m. Start the revolving mirror, and when the curves are sufficiently elongated to permit convenient comparison turn the pointer until the curves are parallel, and take the reading n of the pointer. Turn the pointer still further until the B curve

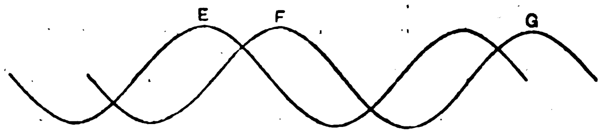

FIG. 2.

has moved through an entire wave length and is again parallel to the A curve and record the new reading p of the pointer. Then the phase difference in degrees between the currents is

$$180 \frac{m-n}{n-p}.$$

The results of these measurements plainly depend on the accuracy of bringing the curves into parallelism. This adjustment can be satisfactorily made by moving A vertically until the curves are brought close together. The apparatus was applied to the measurement of the lag between the branches of a three-phase circuit. Perfect symmetry in the dynamo windings would give 120deg. in each branch, and in any case the sum of the three lags should be 360deg. The values actually obtained are 119·22, 120·44, and 119·44. The sum of these is 359 00, the average deviation (0·92) in this case being not far from the real error.

Among the advantages of the method described above are: (*a*) Since the wave form does not enter the calculation, any source of periodic current may be employed, whether sinusoidal or not; (*b*) slight changes in the electromotive force do not impair the measurements, for their effect is only to vary the amplitude of the curves, a quantity of small consequence; (*c*) constancy in the speed of the revolving mirror is unnecessary, since irregularity affects both curves alike and does not alter their parallelism; (*d*) the approximate value of the lag can be seen at once, as well as the quadrant in which it lies; (*e*) the curves need not fall successively in the same positions on the screen, as no measurements are made there, hence the speed of the revolving mirror need bear no definite ratio to that of the springs; (*f*) the apparatus is simple and easily constructed.

SPECIAL NOTICE.

With this week's number of "THE ELECTRICIAN" is issued (gratis) Supplement Sheet Tables showing Total Capital Outlay and Receipts and Expenditure for the year 1894 of the principal Statutory Electric Supply Undertakings in the Provinces. Complaints of non-receipt should be promptly addressed to the Publisher.

THE PROVINCIAL ELECTRIC SUPPLY BUSINESS.

We publish this week an analysis of the accounts of some nineteen provincial electric supply undertakings in a form similar to that of the analysis of the London companies' accounts published in our issue of June 28th, in accordance with our annual custom since 1892. When we first contemplated this task we had not a few misgivings. At the end of 1894 there were some seventy electric lighting concerns operating in the provinces, and the study of the detailed analysis of seventy capital and revenue accounts set out with all the minuteness required by the Board of Trade seemed likely to send most of our readers away to the seaside with a severe statistical surfeit. To avoid such an undesirable consummation we decided to pass a self-denying ordinance, and to admit no company or municipality to the ordeal—and honour—of financial dissection at our hands unless it had been engaged in the electric supply business for at least a clear twelvemonth, and had an output of the same order of magnitude as that of the least of London's electrical undertakings, that is to say, an output of 100,000 Board of Trade units. In this way about one-half of the Provincial undertakings at work at the end of 1894 were disqualified; and the final outcome of our statistical labours is a detailed analysis of the accounts of eight corporations and eleven companies. Reluctant, no doubt, to raise the envy of its less fortunate neighbours by an irritating display of unequalled figures, the Corporation of Dublin could not bring itself to transmit us a copy of its accounts. Again, owing to their accounts being made up to the end of March or May, several other Corporations, such as Glasgow and Halifax, are still, or were until the last day or so, without a complete financial *exposé* of the past year's working of their electric lighting departments. A few companies also showed a similar dislike to gratuitous advertisement. On the other hand, we have to thank those engineers and officials who were good enough to assist us in our self-imposed task.

Notwithstanding the rapid strides made by the electric light in the provinces within the last two years, the aggregate

electric supply business of the metropolis, calculated on the basis of lamp connections, still exceeds that of all the provincial undertakings, municipal and joint stock, by some 50 per cent. But the metropolitan undertakings not only possess a more imposing total of lamp-connections, they individually do a bigger business. The average annual output of the ten companies and one vestry, which at the end of last year divided the electrical spoils of London between them, was something like one million and a quarter Board of Trade units, whilst the average for the nineteen provincial concerns included in our analysis this week is only slightly over 300,000 units; a figure which, owing to our exclusion of all outputs of less than 100,000 units, by no means represents the truly small average size of the seventy provincial stations at work at the end of 1894. Such being the case, it might have been anticipated that the capital expenditure per unit sold, and the average cost of the unit, would be considerably less inside London than outside. But this is not so. Even if we exclude the London Electric Supply Corporation, the average capital expenditure of the London undertakings per unit sold amounted last year to 5s. 1d., whilst the corresponding figure for the municipal and joint stock enterprises in the provinces is respectively 4s. 6d. and 5s.; if we include the white elephant which resides at Deptford, London must plead guilty to a capital expenditure of considerably over 6s. per unit sold. In regard to the average total cost of the Board of Trade unit, London fares somewhat better, the figure, excluding the London Electric Supply Corporation, being 3·95d., and including that concern 4·19d. Turning to the eight municipalities which figure in our table, it will be seen that the average cost of the Board of Trade unit is 3½d., and in the case of the eleven companies 4½d. Coal no doubt costs more in London than in the northern counties. On the other hand, it must be remembered that the output of the average metropolitan company is immensely larger than the output of the average provincial undertaking, and also that an appreciable percentage of the provincial undertakings are even further off from the coal fields than the metropolis. A clue to the cause of this disparity may, perhaps, be afforded by taking into consideration the sums set aside for depreciation and renewal. In London these sums are, indeed, none too magnificent; in the provinces they are conspicuous by their absence or extreme smallness, municipalities erring almost as much in this matter as companies, the sinking funds of the municipal concerns being taken as equivalent to the depreciation funds of the companies. To what an extent this consideration affects the total cost of the Board of Trade unit is well exemplified in the case of the Liverpool Electric Supply Company and the Newcastle and District Electric Lighting Company. Making no allowance for the sums set aside for depreciation in either case, the total costs come out at 3·56d. and 3·13d. respectively. But if we take into account the £3,838 set aside by the Liverpool Company, and the £720 set aside by the Newcastle and District Company, these figures are respectively reduced to 2·75d. and 2·71d.; nearly reversing the order of merit of the two Companies, and actually doing so if we further take into consideration the fact that while at Liverpool more than 12 per cent. of the gross receipts, at Newcastle less than 9 per cent. of the same was put aside. These are two exceptionally good instances of provincial electric lighting finance; were they not so exceptional, it would not be permissible to attribute as we do some of the unfavourable disparity referred to to the more prudent finance of the London companies, who have not hesitated to burden the Board of Trade unit with the cost of the depreciation of plant inevitably entailed by its production.

REVIEWS.

Hydraulic Motors: Turbines and Pressure Engines. By G. R. Bodmer. Second Edition. (London: Whittaker and Co., and Geo. Bell and Sons. 1895.)

This is the second, revised and enlarged, edition of a well-known and deservedly successful work on hydraulic engines. Mr. Bodmer has given to the public a sound and readable treatise on a subject in which the student had previously been obliged to seek instruction in the German of Redtenbacher, Zeuner, and Weisbach. He follows the method of treatment adopted by these authorities, but by simplifying much of the mathematical discussion of hydraulic theory he has appealed to a larger body of readers, without very seriously impairing the practical value of his work. So far as it goes, Mr. Bodmer's treatise will be as useful as the larger and more comprehensive works on the subject. We say, "so far as it goes," because we believe that this treatise does not go far enough, even for the practical engineering student. There is abundance of information about the turbine itself, but we look in vain for instruction in the important matters of turbine setting and the construction of hydraulic works for bringing the water to and conveying it away from the engine. The reader is given minute detailed directions as to how to design a turbine vane, or how to compute the guide and vane passages; but he is left in total ignorance as to what he is to do with his turbine when he has made it. He is enabled by a mass of elaborate mathematics to predetermine the high theoretical efficiency which a given arrangement and shape of guides and vanes will conceivably possess; but he is not shown how that if his outlying works are not constructed properly this theoretical efficiency will for all time be an imaginary one, and the available head on the mill site will be frittered almost all away before ever the water gets to the beautiful engine. Engineers are far more frequently concerned with the erection of turbines than with their actual internal construction; and a work which treats the turbine as if it were a self-contained affair, a thing complete in itself when you buy it "out of the shop window," cannot appeal to such an extensive class of practical engineers as it would if approached the subject in all its bearings. It may serve as a useful guide to the hydraulic engine builder, but as an engineering treatise the book must be considered incomplete. To be quite fair to the author, and to prevent misunderstanding, we should add that he does give mathematical data in regard to the flow of water through pipes and outside passages; but these are a quite inadequate guide to the proper design of the external works.

But when we turn to the chapters on the various types of turbines, we find a great deal of useful practical information. In the chapter on "Turbines in General" the scheme of classification is drawn up, the author adopting the division under "reaction" and "impulse" turbines. A turbine is distinguished from a water-wheel by the consideration that "motion of the water *relatively to the buckets is essential* to its action," which is the most scientific and best definition we have met with. The conditions involving losses of energy in, and the details of design of, the two classes of turbines are next considered; the mathematical portions of these parts of the book being elucidated by means of numerical problems. The author does not make it as clear as perhaps might be desirable, that in the class of engine which he has called the reaction turbine, the energy of the water is imparted partly by impulse and only partly by reaction; and, although he has stated that in the inward-flow reaction turbine a portion of the head at the vane entrance exists as pressure due to the motion of the engine, he has omitted to show the relation between this pressure-head and the impulse-head, upon which the best efficiency of such an engine very necessarily depends. The design and action of suction tubes, and their utility in combination with reaction turbines, are matters of importance which receive due consideration. The chapter on "Descriptions of and Experiments with Turbines" is a long one, occupying some 126 pages; but it deals with important questions in a useful manner. In this chapter will be

Digitized by Google

found, in tabular form, the details of construction of turbines and particulars of tests of their performance and efficiency. This is by far the most valuable chapter in the book, and it should be welcomed by many an engineer as a carefully compiled collection of useful practical data. The chapter includes an interesting description of the Holyoke testing station, also a short description of the Niagara Falls installation.

The next chapter is on "American Turbines," a rather misleading name for turbines of the mixed-flow type. It is quite true that America is the home of these turbines; but it is also the birthplace of quite distinct types, such as the Pelton wheel. The author summarises the chief points in favour of and against the use of mixed-flow turbines, which, whatever may be said about them, are coming largely into use, and are better adapted to certain falls and classes of work than engines of purer type. Perhaps the worst thing that can be said about these turbines is the practical matter of the tendency of their manufacturers to use cast-metal vanes in stock sizes, instead of setting out the vanes anew for each different speed and fall. Of course, stock sizes are much cheaper than special designs; but the efficiency is liable to suffer badly if the engine selected does not happen to be quite suited to the work and the mill site.

A short concluding chapter deals with "Hydraulic Pressure Engines," or reciprocating water motors. This is not a subject of especial interest to electrical engineers; so we need not do more than repeat the author's observation that this part of his work "is intended merely as a sketch of this branch of hydraulic engineering."

We should add that this work forms one of Messrs. Whittaker's well-known "Specialists' Series," and is got up in the excellent style common to that library of technical books.

Meteorology. By Thomas Russell. (London: Macmillan and Co.)

Mr. Russell's work may be recommended to those who require a book of reference; it is well paragraphed and well indexed, and brimful of those little statistical facts so dear to the transatlantic heart. On the other hand, this volume is not likely to prove particularly attractive to scientific dilettante seeking the latest thing in meteorology and requiring it to be dressed up in a thoroughly digestible form.

NOTES ON SOME EXPERIMENTS WITH ELECTRO-MAGNETIC MECHANISM.

BY P. V. McMAHON.

(Continued from page 351.)

Circular Taper Cores.

The next group of experiments were made with taper cores bent into an arc, the controlling force being a flat spiral spring instead of weights, as in the former experiments with the straight cores. This arrangement had the advantage of the cores being supported by the pivots, and not by an expenditure of energy; also the controlling force increased in proportion to the distance travelled by the core. It can be seen from inspection of the curves, especially in the case of the 5in. and 14in. cores with different springs, that the curve may be made almost any shape by a proper choice of core and spring.

In the first set two cores of Lowmoor iron 8in. long, ⅛in. diameter at the top and ½in. diameter at base, were bent into an arc of 3in. radius; the bottom part of the core was turned down to form a stud, and screwed to take a brass nut, so that the cores could be secured to cross-pieces of different shapes, sizes, and material. This cross-piece had a hole $\frac{3}{16}$in. diameter in the centre, through which passed a $\frac{3}{16}$in. iron spindle about 4in. long; on this spindle the controlling spring and pointer were fixed, and the whole supported in pivoted bearings. Fig. 10 shows arrangement. The spring was secured to a brass sleeve, which could be fixed in any position by a set screw on the spindle; in this manner an initial tension could be given the spring (at the start). The spring first used was 0·315in. wide by 0·02in. thick, 2½in. diameter over outside convolution, and ¼in. diameter in inside (or hole). It had 14 complete convolutions, and was clamped by a small clip attached to the side bearing. In this manner any number of convolutions (or length of spring) could be used. It is also well to notice that the spring was rigidly secured at both ends, and the turning moment was proportional to the amount of winding up. In fact, to prove this the spring itself was calibrated, by putting a small wooden drum on the spindle and attaching a scale pan by a piece of thread to the drum, weights were placed in the scale pan and the angle turned through by pointer observed; the results when plotted gave a straight line, every 10deg. corresponding to 0·21 inch-ounces torque.

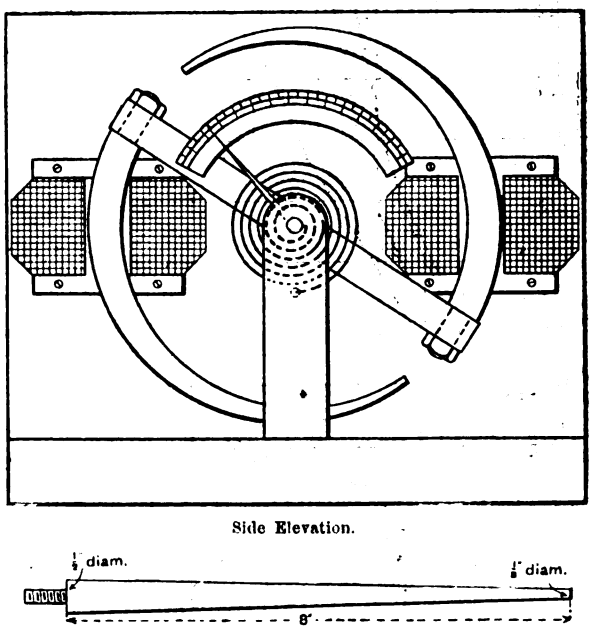

Fig. 10.

The four curves plotted on Fig. 12 show the effect of cross-pieces of different cross-section and material. In all the following experiments with the two 8in. taper cores, the controlling spring was turned through 170deg.; thus at 0deg. on the scale the coil had to exert a sufficient pull to overcome a resistance equivalent to 3·57 inch-ounces torque, and the point of the core was about 0·4in. from the top of the coil. In addition to the scale of degrees on the curve, the equivalent travel in inches of the core is given, and on the right-hand side the torque exerted by the spring against the pull of the coil is given in inch-ounces.

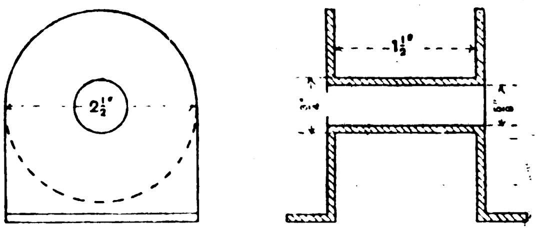

Fig. 11.—The coils first used were each wound with 1,350 turns of No. 26 B.W.G. double cotton-covered copper wire, and had a resistance of 20 ohms at 22°C.

In the bottom left-hand corner is shown the position of the coil, so that the actual position of the core in the coil can be seen by observing the position of core point, which is given by reading the scale of inches. These remarks apply to all curves where one coil was used, except in the case of curve *b* (Fig. 14), which is that obtained by using a zig-zag cross piece; here the point of the core was one inch outside the coil when the pointer was at zero. This divergence is due to the shape of the cross-piece not allowing the core to come far enough back.

Digitized by Google

Referring to Fig. 12, the curve *a* had brass cross-piece $\frac{1}{2}$ sq. in., *b* had iron cross-piece $\frac{3}{8}$ sq. in., *c* had iron cross-piece $\frac{5}{8}$ sq. in., and *d* had iron cross piece $\frac{1}{2}$ sq. in. In this set, for a variation of excitation of 1,250 ampere-turns, the travel of *a*, or brass cross-piece, was 3·95in., and the curve obtained is nearer a straight line than that obtained with any of the other cross pieces. In *b* (the $\frac{3}{8}$ sq. in. iron cross-piece) the travel for 1,250 ampere-turns variation of excitation was 4·55in.

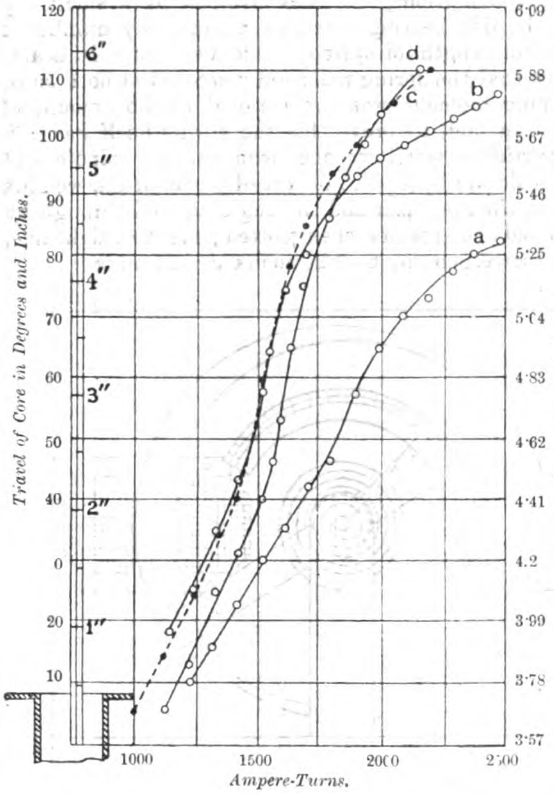

FIG. 12.

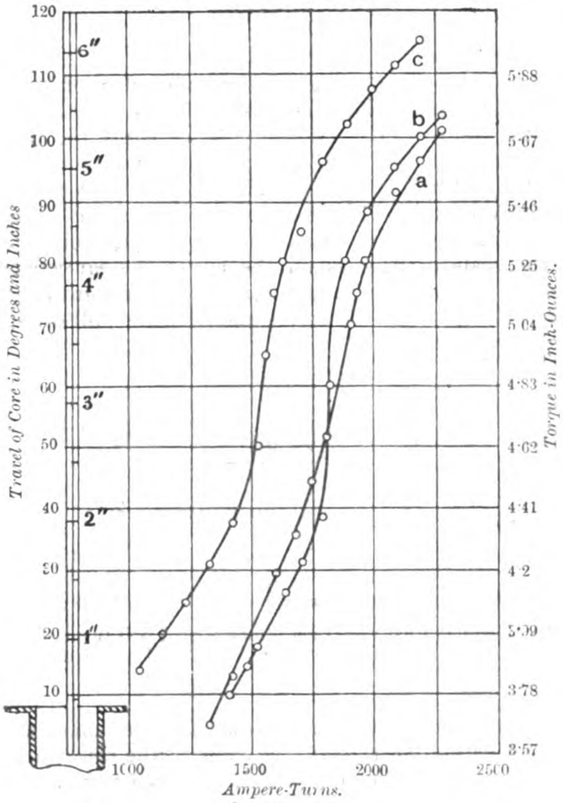

FIG. 13.

With the $\frac{5}{8}$ sq. in. iron cross-piece between the cores (curve *c*) the travel for the same variation of excitation was 5·7in., and with the $\frac{1}{2}$ sq. in. iron cross-piece between the cores (curve *d*) for a variation of 1,250 ampere-turns the travel was 5·7in.

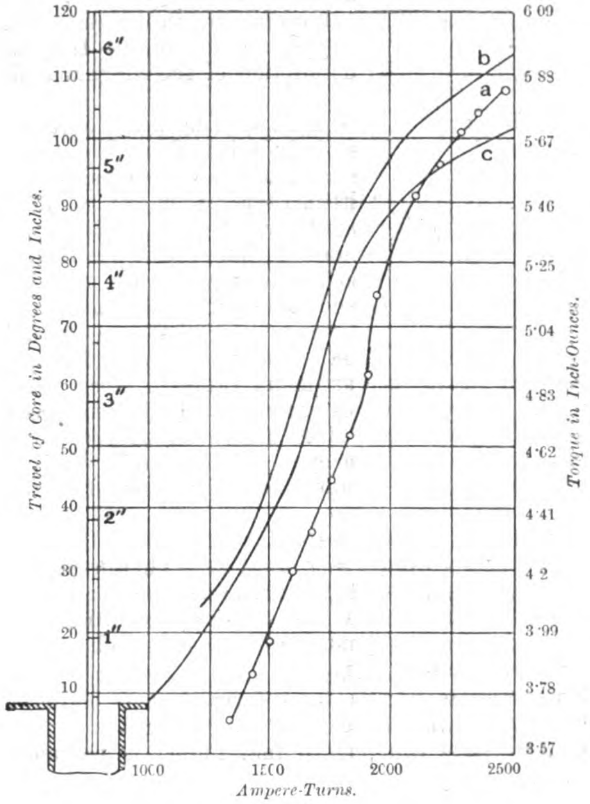

FIG. 14.

Turning our attention to the shape of the curves, it is obvious that curve *a* is nearest to a straight line, although the travel is much less than with the iron cross-piece; in fact, it is perfectly straight until the cross-piece is in a line parallel with the axis of the coils, then it bends off somewhat similar to the curves obtained in the earlier experiments with the straight cores and weights.

Now when the iron cross-piece is used, it entirely changes the shape of the curve; we get a greater travel and a more irregular curve. Altering the cross-sectional area of the cross-piece does not seem to affect the arrangement very much, although it would seem as if the $\frac{3}{8}$ sq. in. iron cross-piece became saturated after travelling 5in., and the curve becomes a straight line. With the $\frac{1}{2}$ and $\frac{5}{8}$ sq. in. cross-pieces the curves are almost parallel to one another, and have the same travel.

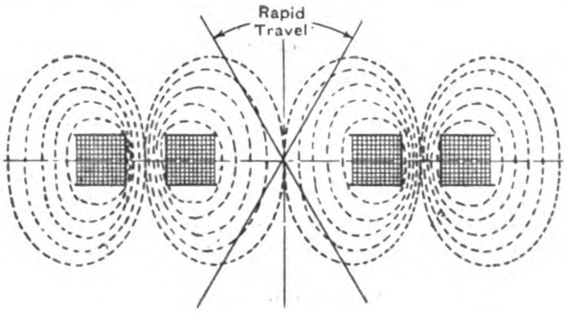

FIG. 15.

The most striking point observable with the use of the iron cross-pieces, no matter what shape or section, is the rapidity with which the cores move when the cross-piece is approaching and leaving the middle position between the coils, making the curve rise very quickly for about 2in. A feasible explanation of this rather peculiar behaviour would seem as follows:—

Mapping out the line of force due to each coil, as shown in sketch (Fig. 15) the magnetic field between the coils is weak, and that on each side near the coils strong. **When the iron cross-piece is nearing mid-position it passes rapidly through**

Digitized by Google

the weak field into the stronger on the other side, so that the rapid travel is not due to the cores, but the iron cross-piece.

To try to overcome this effect due to the weak field between the coils, discs of charcoal iron were placed on the end of the cores and on the spindle between the coils. The results are shown in Fig. 13, curves b and c, and curve a is that obtained with the ½ sq. in. iron cross-piece, as in Fig. 12, curve d. In the experiment b a charcoal iron disc 1½in. diameter, No. 20 B.W.G., was placed on the end of each core, as shown in Fig. 16; this, as might be expected, made matters worse.

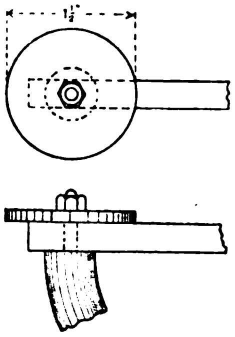

Fig. 16.—Disc on End of Core.

Inspection of the curves makes it clear that b travels more rapidly in the middle than a, and slower at the beginning and end. The travel of the core for a variation of 900 ampere-turns was 5in., that of a being 4·9in. for the same variation of excitation. The use of the disc on the end of the core gives about the worst result, bearing in mind that one of the objects in view is to obtain a straight line.

Next, two iron discs, No. 20 B.W.G., 3in. diameter, were placed on the spindle close to the cross-piece as sketched

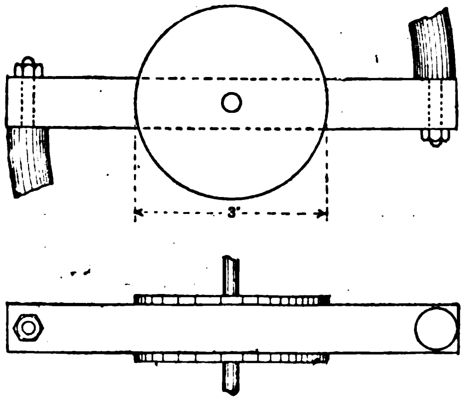

Fig. 17.—Discs between Coils on Spindle.

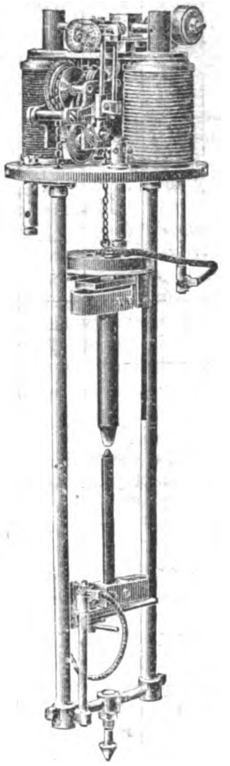
(Fig. 17), the object being to make the magnetic field between the coils more uniform. Curve c shows the result.

The travel for 900 ampere-turns variation was 4·9in., being the same as without the discs. The only effect produced by these discs is to cause the curve to rise more slowly at first, and decrease bending over towards the end of the travel.

(*To be continued.*)

THE BRUSH-VIENNA ARC LAMP.

This lamp is designed either for continuous or alternating currents, and is intended to burn 10 hours normally, but can when the carbons are so proportioned burn from 16 to 20 hours. The lamp consists of a circular plate below which are fixed the guide rods for the carbon-holders and above the regulating mechanism. This latter consists of a series coil and a shunt coil, into which are suspended iron cores fixed to a balance beam. This again is connected by means of a rod to a train of wheels which actuate the two carbons. A second rod is connected to a brake block which acts on the friction wheel of the clockwork. The action of the lamp is as follows: On closing the circuit, the shunt coil sucks in its iron core, raises the further arm of the balance beam and lifts the brake block off the wheel allowing the carbons to approach each other. As soon as the carbons touch, the series coil sucks in its iron core and raises the other arm of the beam, clamps the brake wheel, and by means of the first-mentioned rod lifts the entire clockwork, drawing the carbons apart, and striking the arc. After a certain time the balance gets into a horizontal position. The brake block scarcely touches the wheel, and the feed goes on automatically. The normal length of the arc is, in the case of continuous currents, 2·5mm. to 3mm.; for alternating currents it is only 1mm. to 1·5mm. With a longer arc alternate-current lamps burn with a violet light. The regulation of the lamp is affected by a counterweight. To obtain with a given current a higher electromotive force across the arc—*i.e.*, a longer arc—the weight should be moved along its rod away from the lamp. If further regulation is necessary lead washers can be used. The same procedure holds good if with a constant electromotive force a smaller current is desired. On the other hand, to obtain a shorter arc and a larger current the weight should be moved in the opposite direction, removing, in addition, if necessary, several lead washers. On a 100-volt circuit the direct-current lamps can be run two in series, and the alternating-current lamps three in series.



The mechanism of the lamp will be made somewhat clearer by aid of the accompanying illustration, from which it will be seen that the brake piece which is attached to the right hand rod slides up and down the left-hand rod, which is the one which, actuated by the series coil, lifts the train of wheels when it is required to strike the arc.

NOTES ON THE EFFICIENCY OF ELECTROLYTIC APPARATUS.

In the May number of the *Journal* of the Society of Chemical Industry will be found some "Notes on the Efficiency of Electrolytic Apparatus," by Dr. Hurter, which were read before the Liverpool section of the Society, and which the position of the author, and the circumstance that they furnish the results of experiments made in the laboratory of the United Alkali Company, render of exceptional value. The author points out that "the commercial value of any electrolytic process depends, firstly, upon the cost at which the electrical energy can be produced, and secondly, upon the efficiency of the apparatus which serves to transform the electric energy into potential chemical energy, *i.e.*, the electrolytic cell. The commercial value of an electrolytic process depends further on the first cost of the apparatus, the cost of maintaining it, the length of its life, and finally, upon the amount of manual labour involved in the several transformations of energy, which together constitute the process." There is, therefore, great difficulty in judging between processes. As regards the first cost of an electrolytic cell, this can be fairly well ascertained, but the

Digitized by Google

cost of maintenance and length of life are generally problematical items.

Dealing with the different methods of expressing the result obtained by electrolytic processes of manufacture, the author prefers to state the produce per kilowatt-hour, or *vice versâ*, the number of kilowatt-hours used per kilogramme of the article to be manufactured. The energy consumed in a cell depends, as is well known, on its construction and the polarisation or back electromotive force. In estimating the value of any process, therefore, it is necessary to know the current required, the electromotive force of polarisation and the resistance of the cell, and as there are no reliable data at present from which these factors may be calculated, it is impossible to predict with precision the working of a given process in a given cell.

The author has made what he calls "current efficiency" the subject of special investigations, the result of which will be published later. If the products of electrolysis could be instantaneously removed, the exact electro-chemical equivalent would always be obtained. This has not hitherto been accomplished, though the Castner cell, in which the caustic soda separated forms an amalgam with the moving mercury electrode, is the nearest approach to it. The theoretical importance of the migration of the ions, which was investigated by Hittorf in the years 1853 to 1859, has only recently been recognised, while its technical importance is only just dawning on us; and yet these phenomena are one of the causes of low "current efficiency." In his experiments Hittorf frequently separated his electrodes by four or five diaphragms, so that only the instantaneous removal of the products of the electrolysis can prevent the migration and consequent loss of efficiency. Another important factor is the back electromotive force of polarisation, which, it is now admitted, cannot be accurately calculated from thermo-chemical data. Grave errors are generally avoided, by considering not what takes place in the cell, but what would have to be done with the products of the electrolysis, in order to reform the raw material employed. As these calculations never produce absolutely certain results, it is better to measure the electromotive force of polarisation directly, and for this purpose the author prefers the following method:—

Through a long trough a current is passed between two electrodes. Between these electrodes another very small auxiliary electrode (the position is immaterial) is inserted, which is connected with the anode through a voltmeter of 1,000 ohms resistance, the instrument is observed, and then connected with the cathode in the same way, taking another reading. The potential difference between the terminals of the cell is also measured. Let V_t be the volts between the terminals of the cell, V_a the difference of potential between the auxiliary electrode and the anode, V_k the potential difference between the auxiliary electrode and the cathode; then the electromotive force of polarisation for the electrodes and electrolytes under observation is found to be

$$e = V_p = V_t - (V_a + V_k).$$

A few examples of such measurements are given.

On a large scale the following methods are available: (1) The normal current is passed through the cell under examination, and after the cell has arrived at its normal condition, the current is interrupted, and immediately afterwards the electromotive force is measured with a voltmeter. By this method the value of e usually found is too small. (2) Currents of very different magnitude are passed successively through the cell, and the potential difference at the terminals of the cell is determined, when we get the expression, $e = (V_1 A_2 - V_2 A_1)/(A_2 - A_1)$. If possible, it is best to make three observations, one with a current smaller than the normal, and one with a greater. The electromotive force e is not found as absolutely constant, but increases with the current. The latter method has the advantage of allowing the last of the factors which are required, namely, the resistance, to be calculated. Although the specific resistances of some of the parts of the cell are known, still so much depends on the form and construction that it is not possible to predetermine the resistance of a cell as a whole with any degree of accuracy, and this is more especially the case where diaphragms are employed. The resistance of a cell is chiefly due to the resistance of the electrolyte and to the diaphragm, the resistance of the metallic parts being almost negligible. The resistances of liquids decrease with rise of temperature, and for their determination Kohlrausch's method is the best. The resistance of the diaphragm follows no special law.

As in many processes carbon is the only material available for the construction of the anodes, the author carried out a number of experiments on plates and rods supplied by different makers with a view to determining their resistance and durability. The detail of the experiments and the results are given in tabular form, for which we must refer our readers to the original Paper; but we may state that the carbons of highest conductivity prove more liable to disintegration, but when they have undergone a special heating by a powerful current, or in an electrical furnace, they resist disintegration better, and their conductivity is improved. With regard to diaphragms, their resistance constitutes a considerable, if not the greatest part of the total resistance of a cell; but the less the resistance of the material the less efficacious is it in preventing the ready diffusion of the liquids. Tabulated results are given of experiments tried with diaphragms formed of various woods when used in sheets of $\frac{1}{4}$in. or $\frac{1}{16}$in. in thickness, but the resistance was found in every case to be very high; for instance, a sheet of only 0·006in. would have to be used to keep down the resistance to that of a Portland cement diaphragm of 0·375in. thickness.

CORRESPONDENCE.

STANDARD SCREW THREADS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: The great principle of the division of labour has asserted itself through almost every branch of manufacture, commencing with those where the demand for production of large quantities at cheap rates has rendered the system of producing interchangeable component parts of any apparatus of extreme importance. The American clock and watch trades afford a good example of this. The manufacture of pieces of apparatus which necessarily have to be made in small numbers, or even singly, now requires that the parts going to form such apparatus shall be interchangeable and made on accurate systems.

Among the most important of the component parts of instruments and apparatus of a similar character, are the screws which are used to hold the various parts together, and it is in this direction that attention is necessary.

The British Association in 1884 did good work in laying down systems of diameters and pitches well suited for screws of small diameters, and these are now known as B.A. threads. However, much is left still to be done.

B.A. screws bought to-day from any good makers are not necessarily of the same dimensions as those supplied on a similar order, by the same maker, a month or so ago, and the difference is often fairly large.

The fault does not, in most cases, lie with the screw makers, inasmuch as hardly any two customers who are particular as to accuracy will be satisfied with the same size of screws, even though they are nominally of B.A. threads.

The fault lies in the want of accurate recognised standards for comparison, and in the total want of uniformity in the screw plates nominally termed standards, and sold as such.

To establish a system of reliable standards in accordance with the dimensions laid down by the original Committee would be a work of the greatest importance to both makers and users of B.A. screws, and would undoubtedly tend to assist the production of work having a greater degree of accuracy, and I feel sure that any movement in the direction of removing some of the present difficulties in the matter of small screws would receive the ready support of all interested in high-class work.—Yours, &c., G. K. B. Elphinstone.

London, August 7, 1895.

LEGAL INTELLIGENCE.

Wandsworth District Board of Works v. County of London and Brush Provincial Electric Lighting Co., (Limited).

Mr. Justice STIRLING, in the Chancery Division on Saturday last delivered a reserved judgment in this case, which it will be remembered was a motion by the plaintiffs, asking that the defendants, their servants, &c., might be restrained by injunction from excavating, or constructing or placing in or under any highway within the plaintiff's district any transforming or converting stations or other chambers or receptacles for the purpose of containing transformers.

The arguments on the motion were reported in the last issue of *The Electrician*.

His LORDSHIP, in giving judgment, said that the question was really one of construction of the Order which was granted by the Board of Trade and confirmed by Parliament, and which had all the efficacy of an Act of Parliament. After referring to the scheme of the order, the learned judge said it was obvious that great powers were vested in the Board of Trade. First of all, the system of electric lighting was to be that whic

Digitized by Google

had met with the approval of the Board of Trade, and it was only to be used subject to such regulations as might be imposed by that body; and, secondly, where the operations of the undertakers involved the placing of works under, along, or across any street, the undertakers were to furnish details of what was proposed to be done to three bodies, viz., the Postmaster-General, the Local Authority, and the County Council—and it was left to those bodies to approve or disapprove the plans; in the event of their being disapproved the undertakers might appeal to the Board of Trade, who had the function of adjudicating between the undertakers on the one hand and the three public bodies on the other. All that had been done in the present case. The Board of Trade has fixed upon the system to be adopted. They had defined it in the following manner:—"A high-pressure alternating-current supply at constant pressure to transformers, which will be placed either in converting stations or, when the houses or buildings to be supplied are widely separated, on the consumer's premises. From the converting stations a low-pressure supply at constant pressure will be given to consumers by means of distributing mains. The converting stations will be street boxes of sufficient size and suitable construction to contain several transformers, room being also provided to enable a man to enter the box and conveniently examine the transformers and controlling apparatus." According to the plans of the defendant Company the street boxes which were intended to be used, and which had been sanctioned by the Board of Trade, were receptacles made of iron, of which the dimensions were 10ft. in depth, 7ft. 6in. in length, and 5ft. 6in. in width, and they were to be used for the purpose of containing the transformers which were to change the electricity from high to low pressure. The objection raised by the Wandsworth Board of Works was that the Board of Trade, in sanctioning these receptacles, had authorised something which, according to the terms of the Order, the defendants were not entitled to use. That turned upon the construction of Clause 12. The notice of motion raised two points—first, that the receptacles were not "boxes" under the section; and secondly, that the use of them for the purpose of containing the transformers was not properly sanctioned. His Lordship dealt with those questions separately. First, were the receptacles "boxes" within the meaning of the Act? The "boxes" in common use at the time of the passing of the Order were of much smaller dimensions than those now proposed to be used. But there was nothing in the Act as to size, and it seemed to his Lordship that the question of size was entirely within the province of the Board of Trade. Then it was said that the receptacles were really chambers, and were so designated in the first plans put forward by the Company, but the question was whether they might be described as "boxes." His Lordship thought they might fairly be so described, and the Board of Trade had not gone beyond their powers in sanctioning them. Secondly, might they be used for the purpose of containing the transformers? The uses to be made of "boxes" were defined in the latter part of Clause 12, viz. (*inter alia*), for "regulating, measuring, directing, or controlling the supply of energy." It was not disputed that if the boxes might be used for transformers, the instruments themselves were such as might be properly used. But it was said that none of the words in the Order described the function to which the transformers were appropriated. On the other hand, it was said by the Company that the transformers were apparatus for regulating or controlling the energy. Their effect was to diminish the pressure on a certain ratio depending upon certain conditions, and his Lordship came to the conclusion that the operation clearly came within the words "regulating and controlling," and the Board of Trade had not gone beyond their powers in sanctioning the use of these instruments in the "boxes." The motion was accordingly refused, and, by consent, the hearing was treated as the trial of the action, and the action was dismissed, with costs

Shelfer v. The City of London Electric Lighting Company (Limited), and Meux's Brewery Company (Limited) v. The City of London Electric Lighting Company (Limited).

The cases of Shelfer *v.* the City of London Electric Lighting Company (Limited) and Meux's Brewery Company (Limited) *v.* the City of London Electric Lighting Company (Limited) on Wednesday last again came before the Court of Appeal, composed of Lords Justices Lindley, Lopes and Rigby, on the application of the defendants that the restraint imposed by the Order of the Court dated December 18th last might be suspended until the second motion day of next sittings.

It will be remembered that the injunction was to restrain the defendants from erecting their machinery in such a manner as to cause excessive vibration, to the injury of the plaintiffs' property, the Waterman's Arms public-house, Bankside, Southwark; and when the case was before the Court last week their Lordships extended the stay until Wednesday last.

When the case was called on Lord Justice LINDLEY asked Mr. Fletcher Moulton, the defendants' counsel, what had been done in the meantime.

Mr. FLETCHER MOULTON said that he had affidavits to show that the defendants had done all they could. They had removed three of the four engines, and asked for time to remove the other. As usual, there was the usual conflicting evidence as to the extent to which vibration still existed. That being so, he hoped that their Lordships would in mercy to the parties appoint an independent expert who would either report to their Lordships or direct what was to be done. He did not think it was possible for their Lordships satisfactorily to ascertain what the facts were on affidavits when the affidavits were so completely contradictory as they were in the present case.

Mr. WARMINGTON, Q.C., who appeared for the plaintiffs (the respondents on the motion) said that whatever the defendants were doing on their premises the plaintiffs were still suffering, and he (the learned Counsel) had an affidavit to that effect.

Mr. FLETCHER MOULTON said that it was not in his favour to ask for an independent expert, but it would enable the defendants to go to the realities of the case.

Mr. WARMINGTON said he agreed that something was done on July 28th, two days before the extension of time expired. What he was anxious about was that the defendants should be put upon terms. He thought that if their Lordships gave them (the defendants) till the Court met again after the Long Vacation it would be sufficient. The defendants had seen the affidavits filed by the plaintiffs, and knew that what they had done had not removed the vibration.

Mr. FLETCHER MOULTON said that the defendants asked for a suspension until the second motion day of the Michaelmas Sittings.

Mr. WARMINGTON said that he did not object to that, and

Their LORDSHIPS accordingly made an Order on the motion in those terms.

Mr. FLETCHER MOULTON asked if the plaintiffs would agree to the defendants having liberty to inspect their premises at reasonable times.

Mr. WARMINGTON: Oh, yes.

Bryson v. Crieff Police Commissioners.

This was an appeal case in which the pursuer, W. A. Bryson, consulting electrical engineer of Glasgow, appealed against the verdict of Sheriff-Substitute Grahame, who, it will be remembered, found that he had failed to prove employment by the defenders, either as individuals or jointly or severally, to perform the services which he alleged he had performed, or to incur the travelling expenses and incidental outlays charged in the account sued for in connection with the introduction of the electric light into Edinburgh. Sheriff Jameson, who heard the appeal, has issued an interlocutor, recalling his Substitute's finding as to expenses, but otherwise adhering to the interlocutor. The Sheriff finds the pursuer liable to the Commissioners in expenses, also to the defender Adie in expenses, and *quoad ultra* finds no expenses due.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.—Tenders are invited by the Vestry of Hammersmith, London, W., for complete schemes for public and private lighting, and for the supply of motor power in the compulsory area of the Vestry's Provisional Order. Further information is given in our advertisement columns, and full particulars can be obtained of Mr. H. Mair, Surveyor to the Vestry. Tenders have to be sent in by 6:30 p.m. of Wednesday, Sept. 4th.

——— It will be seen from our advertisement columns that the Vestry of St. Mary, Islington, invite tenders for the wiring of the Vestry Hall and municipal offices. Specifications, plans and particulars can be obtained from the electrical engineer to the Vestry (Mr. Albert Gay), 50, Eden-grove, Holloway, N., on and after 13th instant. Tenders, addressed to the electrical engineer, must be in by 12 noon on Tuesday, 27th instant.

——— The Commissioners for the Control of Lunatic Asylums, Dublin, invite tenders for wiring the Killarney District Lunatic Asylum for the electric light. Plans and specification may be seen at the Asylum or at the Office of the Engineer, Mr. W. Leake, 30, Victoria-buildings, Manchester, and tenders, addressed to the Secretary, Board of Control, Custom House, Dublin, must be in by 10 a.m. on the 30th instant. Further information is given in our advertisement columns.

——— The Electric Lighting Committee of the Wakefield Corporation invite tenders for the supply and erection of (*a*) boiler and fittings, mechanical stokers and engine, economiser, feed pump, injector, &c.; (*b*) steam alternators, condensers, oil filter, fittings, &c., steam, exhaust, feed, blow-off and sundry pipes, valves and water tank, &c.; (*c*) main switchboard and instruments; (*d*) cables, junction boxes, culverts, and trenching, &c.; (*e*) transformers and switchboard, &c.; (*f*) arc lamps and posts; (*g*) meters, and (*h*) overhead crane. Tenders, addressed to the Town Clerk, must be in by 2 p.m. on August 24th.

——— The Blackpool Corporation are willing to receive tenders for the right of user for a period of seven years of the electric tramways in Lytham-road, and which extend northwards from the southern boundary of the borough for about two miles. An approved overhead wire and trolley system is to be used for a portion of the route, and for the remainder the conduit or central channel system now laid down by the Corporation under the roadway. All particulars can be obtained of the Town Clerk, to whom tenders have to be sent in by August 17th before 12 noon.

——— The Vienna (Austria) Municipal Authorities invite tenders for a railway system worked by electric power in the municipal district of Vienna. Further particulars are given in our last issue, and tenders have to be sent in to the Wiener Stadt Bauamt, Rathaus, Vienna, not later than November 4, 1895.

Digitized by Google

Tenders Invited.—The Dutch Minister of the Colonies invites tenders for the supply of a quantity of iron telegraph poles. Tenders to be sent to the Technical Bureau, Ministry of the Colonies, The Hague, by the 21st instant.

——— The Corporation of Portsmouth require tenders for laying about seven miles of stoneware ducts for electric light cables. Tenders, addressed to the Chairman of the Electric Lighting Committee, must be delivered by the 14th instant.

——— The Urban District Council of Portland invite tenders for the lighting of the district of Portland from September 1st to April 30, 1896 by electricity, gas or oil. Tenders must be sent in to the Office of the Council, New-road, Portland, by 13th inst.

——— The Allgemeine Elektricitäts Gesellschaft of Berlin invite tenders for the supply of high-pressure steam boilers for large central electric generating stations. Further particulars of the Company, 22, Schiffbauerdamm, Berlin, N.W.

Tenders Accepted.—The Building Committee of the Cardiff Free Library have accepted the tender of Mr. Thomas Brawn, of Birmingham, for wiring and fitting up the central library for the electric light. The amount of the tender is £253. 11s. 1d.

——— The Salford School Board have received the following tenders for wiring the new offices of the Board for the electric light, and for the fixing of electric bells and speaking tubes :—

Wiring.

Messrs. Verity and Sons' tender for the fixing of speaking tubes, for the sum of £6, has also been accepted.

——— The Vestry of St. George's, Hanover Square, London, W., have accepted the tender of Messrs. Strode and Co., for wiring and fitting up the Vestry Hall and offices for the electric light, for the sum of £278. 5s.

——— The General Purposes Committee of the St. James's Vestry, London, S.W., have received the following tenders for wiring the Town Hall for the electric light :—

	£	s.	d.
Freeman and Co. (*accepted*)	£39	0	0
C. J. Smith	38	15	0
B. Verity & Sons	45	7	7

——— With reference to a Trade Note which appeared in our issue of July 26th announcing that a tender of Messrs. Thorpe and Waring had been accepted by the Metropolitan Asylums Board for the supply and running of mains and wiring of buildings at the North-Western Fever Hospital, Haverstock Hill, London, N.W. This information was obtained through the usual source, but, so far as it refers to Messrs. Thorpe and Waring's tender being accepted, is erroneous. The complete list of tenders, together with Prof. Ayrton's report to the Metropolitan Asylums Board on the subject, will be found on pages 500 and 501, and it will be seen that the Board have finally decided to accept the tender of Messrs. Fowler, Lancaster and Co., of Graham-street, Birmingham, for the sum of £859. 15s. This is £300 in excess of the lowest tender, but has been accepted as offering the best system for the work under the contract.

Tenders Received.—The Electric Lighting Committee of the Belfast Town Council have decided to recommend the acceptance of the following tenders for stores for the Corporation electricity works: Messrs. Shaw and Co., cast-iron pipes; Messrs. Doulton and Co., insulators; British Insulated Wire Company, copper strip; the Callender Company, cables; and Messrs. Coates and Son, road work.

——— The Electric Lighting Committee of the St. Helens Corporation recommend for acceptance the following tenders for the supply of electric lighting plant:—Yates and Thom, boiler-house plant; Johnson and Phillips, engine-house plant; S. Z. de Ferranti, switchboards; British Insulated Wire Company, underground work: John Fowler and Co. (Leeds), transformers; Chamberlain and Hookham, meters; Carrick and Ritchie, travelling crane.

Appointment.—Messrs. Burnett and Hooper have been appointed by the St. Pancras Vestry electricians at the King's Road station.

Appointments Vacant.—The Governors of the Woolwich Polytechnic are willing to receive applications for the posts of lecturer in physics (salary £110 for a session of about eight months) and lecturer in mechanics (salary £70 for a session of about eight months). Some further particulars are given in our advertisement columns, and applications must be sent in by the 23rd inst.

——— The Governing Body of the Northampton Institute, Clerkenwell, E.C., are prepared to receive applications for the appointment of a principal. The salary attached to the office has been fixed at £600 per annum. Applications must be sent in by September 4th to Mr. J. J. Lambert, 8, Dowgate-hill, Cannon-street, London, E.C.

——— The Stockton School Board require a head master for their Higher Grade and Organised Science School. Salary £300 per annum. Applications by Tuesday, 20th instant, to the Clerk to the Board 19, Dovecot-street, Stockton-on-Tees.

Dissolutions of Partnership.—Messrs. H. G. Ellis and G. E. East (the younger), who have hitherto carried on business as electrical engineers under the style of the London Battery Company at 16, St. Ann's-street, Westminster, London, S.W., have dissolved partnership.

——— The partnership business of art metal workers hitherto carried on by Messrs. J. S. Gardner and Caroline Gardner, under the style of Starkie, Gardner and Co., at 29, Albert Embankment, Lambeth, London, S.E., has been dissolved.

——— Messrs. R. C. Kerr and J. Vallentine, electro-platers, trading as the Empire Plating Works, at 18, Kirby-street, Hatton Garden, London, E.C., have dissolved partnership.

——— Messrs. E. Hancock and F. Hulbert, carrying on business as carbon plate makers under the style of Hancock and Hulbert, at Richmond-place, New-road, London, S.W., have dissolved partnership.

Personal.—Mr. John F. C. Snell has been appointed resident engineer at the new electric lighting and refuse destructor station (King's-road) of the St. Pancras Vestry. Mr. Snell has been engaged supervising the erection of this station for the last seven months, and was formerly chief assistant engineer at the Stanhope-street station. He was also chief assistant to Major-Gen. C. E. Webber and on Messrs. Crompton's staff.

Bankruptcy.—The first meeting of the creditors of Ronald A. Scott, electrical engineer, was held on Wednesday last. The debtor's statement shows liabilities amounting to £10,787. 2s., £3,832. 2s. being due to unsecured creditors and £4,180 to secured creditors, whose securities are estimated to produce £10,000. To partly secured creditors £2,775 is owing, securities in this case being estimated to produce £450, leaving a balance of £2,325 to rank against the estate for dividend, the total liabilities of the estate being £6,157. 2s., with an estimated deficiency of £337. 2s. The debtor states that he has now no business. He commenced business in 1889 as an electrical engineer at Acton with a capital of about £900, and continued in business till June, 1894, when he turned his business into a limited liability company under the style of Ronald A. Scott, Limited, with a nominal capital of £10,000 in shares of £1 each, of which the debtor was to receive 5,000 which were duly allotted, the debtor acting as manager. In December, 1894, a Receiver was appointed, who carried on the business until May last, when it was practically closed. There are 120 unsecured creditors, chiefly for goods supplied. The debtor attributes his present position to bad trade and competition, and to losses in bringing out advertising patents. (The debtor is the gentleman who "illuminated" the Nelson statue at Trafalgar-square.) A fairly representative group of creditors were present at the meeting, but as the proofs were not lodged in time for a vote to be taken, no resolutions were passed, the Official Receiver remarking that it seemed something like the case of Dr. Jekyll and Mr. Hyde, the Company having been formed as "Ronald Scott (Limited)" to take up the liabilities of "Mr. Scott," "Mr. Scott" remaining in the business as manager. There were no shareholders beyond the debtor and the seven subscribers to the Memorandum; there were no directors, no secretary, "no nothink." The debtor said he did not think the original Agreement with the vendors had been registered at Somerset House; he had raised £5,000 in debentures on the Company, but they were now in the hands of creditors. Some amusement was caused by certain details given by the Official Receiver, and at the list of articles assigned by the debtor when he turned himself into a limited liability company. Very little consolation was derived from the meeting by the creditors present, who will have another opportunity of discussing matters with Mr. Scott six weeks hence.

Digitized by Google

LIQUIDATIONS.—At a meeting on June 26th last it was resolved to wind up the Universal Electric Lighting Company (Limited) voluntarily. This resolution was confirmed on July 12th, and the Secretary (Mr. J. G. B. Elliot, 18, Eldon-street, London, E.C.), to whom claims must be sent by September 7th, was appointed liquidator.

——— At a meeting of the proprietors of the International Electric Storage (Limited), on June 26th, it was resolved to wind up the Company voluntarily. This resolution was confirmed on July 12th, and the Secretary (Mr. J. G. B. Elliot) was appointed liquidator. Claims have to be sent in by the 7th prox. From a notice in another column it will be seen that the I.E.S. Accumulator Company has been formed to manufacture the I.E.S. batteries.

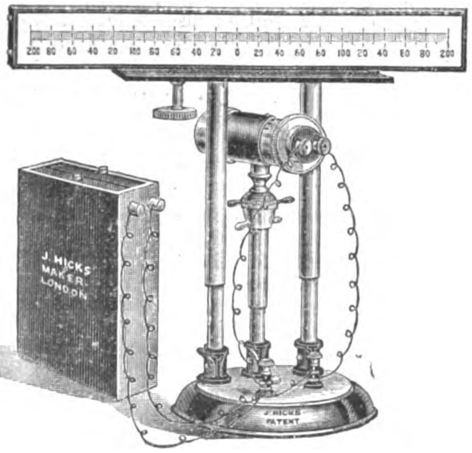
——— It was resolved on July 1st that the Keighley Electrical Engineering Company (Limited) be wound up. This resolution was confirmed on July 22nd, when Mr. E. Clough, Cemetery-lane, Keighley, was appointed liquidator, and was authorised to transfer the assets and liabilities to another company proposed to be formed and registered.

——— A meeting will be held at 59 and 60, Wind-street, Swansea, on the 10th prox., at 11 a.m., to receive an account of the winding up of the Lundy Cable Company (Limited).

——— A petition has been presented by Mr. J. L. Fuller, electrical engineer, trading as Fuller and Co., 28, Bush-lane, Cannon-street, London, E.C., to the County Court of Worcestershire, for the compulsory winding up of the New British Electrical Installation Contractors (Limited), and will be heard at the Shire Hall, Worcester, on the 21st inst., at 10 a.m. Messrs. Scott, Spalding and Bell, 15, Queen-street, London, E.C., are the petitioner's solicitors.

NEW BRANCH.—It is stated that the St. Petersburg branch of Messrs. Siemens and Halske are about to establish branch works in Odessa.

GALVANOMETER SCALE AND LAMP.—Mr. J. J. Hicks, of Hatton Garden, London, E.C., is the sole manufacturer of Burstall's galvanometer scale and lamp (Hicks's patent), of which we give an illustration below. The scale and lamp has been designed so as to be portable, rapidly adjusted, and to work in the open daylight. The focussing tube is carried on a ball joint, and by means of a sliding tube can be set at any required height; when the spot of light has been thrown on to the mirror, both these motions can be



locked, so that focussing can be done without fear of the spot being shifted off the mirror. The scale is divided in millimetres on ground glass, and is capable of adjustment both vertically and horizontally, the latter adjustment being by means of a rack and pinion. The source of light is a small glow lamp, worked by two storage batteries. A fine line is etched on the object glass, and this line is focussed on the scale. By means of hinged joints the lamp and scale can be folded into a very small compass, by no means a small consideration for portable work.

ADMIRALTY CONTRACTS.—The United Abestos Company (Limited), of Dock House, Billiter-street, London, E.C., have been awarded the contract for the supply of asbestos packing and other goods to the Admiralty for the ensuing year (1895-6).

D.P. BATTERIES.—The makers of these batteries announce that several novel developments have recently been made, with the result, it is claimed, that a plate has now been produced which will resist very considerable ill-treatment. For country house work, where skilled attendance is not always available, the improvements recently effected will be appreciated.

ELECTRIC LAUNCH.—An electric launch has been shipped from Messrs. T. and G. Tagg and Son's Boat-building Works, East Molesey, Surrey, to the Imperial Palace, St. Petersburg, to the order of the Czar.

WESTINGHOUSE ELECTRIC COMPANY (OF AMERICA).—It is stated that this Company has entered into a working arrangement with Messrs. Burnham, Williams and Co., proprietors of the Baldwin Locomotive Works at Philadelphia, who possess one of the largest and best-equipped railway locomotive works in America.

J. G. STATTER AND CO.—Mr. J. G. Statter notifies us that he has purchased the designs and goodwill of Messrs. J. G. Statter and Co. (Limited) (in liquidation), and that the firm will be carried on under the style of J. G. Statter and Co.

WRONGFUL DISMISSAL.—The Blackman Ventilating Company (Limited) were sued in the Lord Mayor's Court, London, by Mr. Watel, an electrical engineer, for wrongful dismissal. The plaintiff is the patentee of a electric fan, and granted a license of his patent to the defendants in 1890, part of the consideration being that he should be retained as engineer. The evidence having satisfied the judge and a jury that the plaintiff's claim was a reasonable one, a verdict was returned for the plaintiff for £50.

OUTING.—The works staff of the D.P. Battery Company travelled on Saturday last to Hastings, where a dinner was provided at the "Royal Albion" Hotel, under the chairmanship of Mr. J. Jones, works manager.

ABERYSTWYTH.—The pier was lighted electrically for the first time on Saturday last.

ACTON.—Electric lighting matters seem to have arrived at a decidedly uncertain stage in this district. It will be remembered that some time ago the District Council agreed to transfer its Provisional Order to Messrs. New and Mayne. In April last it was, however, agreed to ascertain the views of the parochial electors before finally transferring the Order, since when nothing has been done. Recently the Capital and Counties Electricity Supply Company gave notice of its intention to apply for a Provisional Order to supply electric current, and the Council decided to oppose this application. At the last meeting of the Council a letter was read from a prominent local ratepayer asking when electric current would be available, and the Works Committee recommended that he be informed that "there was no immediate prospect of the electric light being brought into the district."

ASYLUM LIGHTING.—The Metropolitan Asylums Board on Saturday last adopted the report of the North-Western Hospital Committee, recommending the acceptance of the tender of Messrs. Fowler, Lancaster and Co., for running mains and wiring the five new wards and other buildings being erected at the North-Western Hospital, for the sum of £859. 15s. The plans and specifications were prepared by Prof. Ayrton, to whom the 17 tenders received were referred for report. Prof. Ayrton reports that when it was decided to electrically light the new buildings he applied to the Westminster Insurance Office for permission to use a conduit system, but as that office had to obtain the consent of other insurance companies interested in the risk, it was some time before the necessary permission was given, and it was then coupled with a preference for a non-metallic tube. Under these circumstances, and especially as the details of several of the conduit systems are covered by patents, and therefore can only be used with the permission of the holders of the patent, Prof. Ayrton considered it undesirable to specify the material of the conduit with particular minuteness. To enable any firm to tender prepared to employ a conduit system, as distinguished from the old-fashioned wooden casing, he specified that "Samples of the conduit which the contractor proposes to use must be sent with the tender." The list of tenders on the opposite page gives a description of the material proposed to be used. Prof. Ayrton, after a careful survey of the 17 tenders received, and of the samples, reports that the Board will, in his opinion, receive the best value from the tender of Messrs. Fowler, Lancaster and Co., for £859, 15s., as—

(i.) Zinc tubes, such as those proposed, are much stronger than those made of bituminised paper, and will stand the action of damp and of cements better than paper.

(ii.) Zinc is stronger than earthenware unless the latter be very thick; further, zinc tubes can be obtained in greater lengths, and also can be joined together more easily, than earthenware tubes. Therefore zinc is to be preferred to earthenware for mechanical reasons, and, when insulated wire of the class stated in the specification is employed, no electrical advantage is practically gained by using a tube composed of non-conducting material.

(iii.) As Messrs. Fowler-Lancaster are prepared to use steel tube where, in my opinion, there is a special risk of mechanical injury, their system is nearly as good as one in which iron pipes are used throughout.

(iv.) The tender is nearly £200 less than the lowest of those in which iron pipes are quoted for, and only £300 more than the lowest tender of all. And as this latter is for a simple paper tube system I do not recommend its adoption.

(v.) As the zinc tubes are made out of *rolled sheet*, and as the steel tubes they use are *smooth inside*, there is far less risk of damage to the insulation of the conductors in drawing in than if rough gas barrel were employed, as is contemplated in some of the higher tenders.

The Board having received a tender, which is only fifth from the lowest, for a combination system of special zinc tube and

smooth steel pipe, Prof. Ayrton considers that this furnishes a conclusive proof of the advantage derived from the material of the conduit having been left open in the specification.

BANGOR.—Mr. F. H. Medhurst has presented his amended report and estimates on the question of the introduction of the electric light into Bangor, and the Electric Lighting Committee now report that they have considered the same, and recommend that the Council apply for a Provisional Order, and that the Committee be empowered to take the necessary steps to carry out the scheme. Dr. Grey Edwards said they should be guided by what occurred in Liverpool, where the Corporation allowed a company to take up the electric lighting, and Liverpool had now to pay for its remissness something like £400,000! After a long discussion, an amend- was moved by Alderman T. Lewis that the matter be referred back for further consideration, and the original motion having been withdrawn, the amendment and the proposals of the Committee were accordingly referred back.

BROADSTAIRS (KENT).—The Brush Provincial Company recently gave the Broadstairs and St. Peter's Urban District Council notice of their intention to apply for a Provisional Electric Lighting Order for this district, and the Works Committee, to whom the matter was referred, recommended that the application be opposed. At the last meeting of the Council Mr. Councillor Horrell, in moving the adoption of the Committee's report, said it did not necessarily follow that the Council intended to oppose the introduction of electric light at all times into the district, but he thought it should go forth that the Council opposed this application in order to retain the electric lighting powers in their own hands, and to be able to use them when the proper time came. The motion was carried.

BLACKBURN.—The Town Council at their last meeting considered the recommendations of the Gas Committee as to the proposed extensions of the electric lighting scheme, and, as these recommendations were unfavourable to the proposal, and as the Committee itself is favourable, after a short debate, the matter was referred back for reconsideration.

CHELTENHAM.—The electric light is making very satisfactory progress in Cheltenham. The report of the Lighting Committee recently presented to the Town Council states that they have now 57 applications for current on their books. They had an equivalen of 2,160 8-c.p. lamps actually connected, while other applications brought up the total to well over 3,000 lamps. In face of this rapid increase, and without taking into account the question of street lighting, they were in danger of being overtaken by the demand, and the Committee would, at its next meeting, make some recommendation for an increase of the plant at the generating station. As their authorised capital had been expended, the Committee recommends that application be made to the Local Government Board for sanction to borrow a further sum of £10,000 for these extensions. The report was adopted. The thanks of the Committee have been voted to Mr. Preece for his gratuitous services in connection with the introduction of the electric light.

CHURCH LIGHTING.—Trinity Church, Leeds, is being fitted for the electric light by S. Dixon and Son. About 100 lights will be used.——It is stated that the Sacred College at Rome have under consideration the question of introducing the electric light into Roman Catholic churches, the use of wax candles being retained for the celebration of sacred ceremonial rites.

DARFIELD (YORKS).—The lighting question was discussed at the last meeting of the Parish Council. A discussion took place on the report presented by the General Purposes Committee on the gas supply, and a motion that the Committee reconsider the whole question, including an inquiry as to the cost of lighting the streets by electricity, was defeated by five to three.

DERBY.—The Electric Lighting Committee report that in consequence of the still rapid increase in the demand for electricity, they have had under consideration the desirability of enlarging the present station, and it has been decided to recommend the Council to grant a sum of £3,490 to enable them to build an annexe to the present station and to provide a 250 H.P. engine and alternator with exciter, including steam pipes and all connections and additions to the switchboard. The Committee recommend the Council to make application to the Local Government Board for sanction to borrow this sum. The Committee also report that the borough accountant has prepared a capital and revenue account of the electric light undertaking.

DOVER.—The lighting of Snargate street by means of arched lamps was decided upon by the Town Council some time back, but, notwithstanding, has not yet been carried out. The gas interest is strong at Dover, and a motion by Mr. Councillor Thorpe at the last meeting stops further proceedings for the present.

EDINBURGH.—The demand for electric current seems to increase at a rapid rate in Edinburgh. Recently the mains were extended to Hope Park-terrace in the South Side district, and already a number of the leading merchants are having their establishments wired and fitted up for the electric light. One of the first to use the light was Mr. James Lyle, whose premises at the University corner have been fitted up by Messrs. Milne and Sons.

FIRE.—A fire broke out on the 1st inst. on the premises of Messrs. Mackey, Mackey and Co., of 175A, Grange-road, Bermondsey, S.E. Although some slight damage and inconvenience were caused by the outbreak, we are informed that business will not in any way be interfered with.

FOLKESTONE.—The Mayor and Town Council recently held a conference with the Directors of the Dover Electricity Company in order to discuss the proposal to light Folkestone from the Dover works. The proposal is to run a cable along the South-Eastern Railway from Dover to Folkestone, by which means it is claimed current could be supplied at a minimum cost. The matter is to be brought before the Town Council, when a committee will be appointed to confer with the Dover Company.

FOREIGN POSTCARDS.—Timely warning is given by a British Consul of annoyance likely to be caused by the practice, which is growing, of sending private postcards, with an adhesive penny stamp attached, to the Continent and other parts abroad. These private cards are treated as letters, and a surcharge is made of 3d. upon each communication.

GLASGOW.—At the last meeting of the Town Council the report of the Gas and Electric Lighting Committee (referred to in our last two issues) was formally adopted. Mr. Mitchell, who moved the adoption of the report, said he regretted that there was not a profit on the electrical department, but no doubt the result would be altered in the near future, and he anticipated that the plant at Waterloo-street and John-street would be fully occupied during the coming winter.

Digitized by Google

HAMPSTEAD (LONDON, N.W.).—The Vestry at their last meeting discussed the report of the Electric Lighting Committee recommending certain extensions of the electric lighting plant, and, after some discussion, the report was referred back for further consideration. The chairman, in referring to the intolerable heat of the Board-room, suggested that the Works Committee should be asked to fix an electrically-driven fan in the room, and this suggestion was adopted. The Board of Trade forwarded a copy of a memorandum of Major Cardew with reference to the application of the Vestry for the Board's consent to the placing of four 25-kilowatt transformers in certain sub-stations, and stating that under the circumstances the Board was unable to consent to this. It was decided, on the recommendation of the Lighting Committee, that the salary of the chief assistant engineer (Mr. E. Sayer) be raised from £104 to £200 per annum as from May 1st.

HOSPITAL LIGHTING.—At the quarterly court of the Governors of the Hospital for Consumption (Brompton, London, S.W.) last week the Committee of Management reported that they had decided, after much deliberation, to light the whole of the hospital by electricity, as it was felt it would be to the great advantage of the patients, and the expense would be amply justified. The Committee's report was unanimously adopted.

KILLARNEY.—The Killarney Electric Light Company have written to the local Board of Guardians pointing out that the Board of Control had decided to light the district asylum electrically, and suggesting that the Vice-Guardians should also adopt this method of lighting the workhouse. Particulars of the tenders for lighting the asylum will be found in another column.

KINGSTON-ON THAMES.—The electrical engineer has been instructed to submit an estimate of the cost of wiring the sewage works for the electric light, and for the supply of current thereto. The Town Clerk recently wrote to the Surbiton District Council inquiring whether Surbiton and Hampton Wick would be likely to require current from the Kingston electricity station, and at the last meeting of the Council a reply from the Surbiton Council was received, stating that they proposed to establish electric works of their own. The Town Clerk has also written a similar letter to the Malden District Council. The engineer's report states that the receipts from the sale of current and for meter rents for the half-year ended June 30th were £731. 4s. 1d., compared with £336. 10s. for the corresponding period of last year. The Lighting Committee have resolved to introduce the Brighton method of charging for electric current.

LEYTON (LONDON, E.).—At the last meeting of the District Council the Electric Lighting Committee reported that they had considered Prof. Henry Robinson's recently-presented report on the lighting of the district by electricity. Prof. Robinson estimates the initial cost of the installation (including land, buildings, plant, &c.) at £16,200, the annual up-keep at £2,072, and the revenue at £2,280. The central generating station will be as nearly as possible in the centre of the district, probably in the neighbourhood of the Grove Farm, and the land and building is estimated to cost about £5,600. The scheme provides for the laying of five miles of mains altogether. It is intended to put down plant capable of supplying 150 arcs and about 5,000 16 c.p. incandescents, but it is not intended to expend the whole of the capital at the outset, as the installation will be carried out by degrees. The charge for current to private consumers will be 6d. per unit, and it is estimated that the lighting of the public buildings will be effected for £200 a year less than the present cost of gas. The Committee also reported that they had, in conjunction with Prof. Robinson, inspected the process of gas manufacture in connection with the gas engines used for driving the dynamos at the Midland Railway Company's station and goods yard at Leicester, and, having carefully considered the practical working of the scheme, they had no hesitation in recommending the Council to authorise the prompt erection of the proposed works. As the Council have decided to adopt the electric light for their new Public Offices and Technical Institute, the Committee further recommend that Prof. Robinson be instructed to prepare the necessary plans, specifications and estimates, and that application be made to the Local Government Board for sanction to borrow £16,200. It was originally proposed to borrow only £14,200, but as it is intended to extend the mains along the Leytonstone-road, and as the land for the proposed central station will cost an additional £350 beyond the sum first proposed, it was decided to increase the amount to the larger figure. It was further recommended that the Committee be authorised to negotiate and enter into a provisional contract (if necessary) for the purchase of the land required. Councillor Bare, who moved the adoption of the report, said the Committee had unanimously come to the conclusion that the Council could not do better than adopt an electrical system of public lighting, and were satisfied that the system proposed to be adopted was the best and most economical. After considerable discussion the report was adopted with only four dissentients. The Hall Building and the Electric Lighting Committees jointly recommended that Prof. H. Robinson be instructed to prepare plans, specifications and estimates for wiring and fitting up the public buildings, and that tenders for the same be invited from 12 electrical firms to be selected by Prof. Robinson. This recommendation was also carried.

LIMERICK.—At a special meeting last week, the Town Council discussed the electric lighting question. A Provisional Order was obtained in 1892, and towards the end of 1894 the Board of Trade gave notice of its intention to revoke the Order unless evidence was forthcoming that the Council intended to comply with its provisions. Under these circumstances the Council invited Prof. Kennedy to prepare an electric lighting scheme for the town. This scheme has been duly formulated in a report recently presented to the Council. Prof. Kennedy estimates the initial cost of an electric light installation at £18,000. Mr. Bourke moved that the necessary steps be taken to put the provisions of the Electric Lighting Order in force, and that the Local Government Board be asked to hold an inquiry into their application to borrow £18,000 for that purpose. After a long and somewhat incoherent discussion, the original resolution was finally adopted.

LIVERPOOL.—The report prepared by the Chairman of the Lighting Committee with regard to the purchase of the Liverpool Electric Supply Company's undertaking was presented to the meeting of the Corporation on Wednesday, and deals exhaustively with the history of the introduction of the electric light into Liverpool. It is pointed out that the earliest date fixed for the purchase of the Company's undertaking by the Local Authority is the year 1898, subsequently extended to 1890 on certain conditions. The Corporation having decided that, if satisfactory arrangements could be made, an earlier purchase should be effected, negotiations were in the current year entered into with the Company, and experts were called in to advise the Corporation in these negotiations. Expert opinion was to the effect that the Corporation would be well advised in making the purchase, and an agreement was in May last prepared, in the terms of which the Company undertake to sell and the Corporation to purchase the entire undertaking for the sum of £400,000. The agreement is a lengthy one, and stipulates amongst other conditions that the purchase-money shall be paid over by September 2nd, or at latest on January 1st next; that the Corporation shall be liable to, and shall pay and discharge all debts and liabilities of the Company existing on the date of the completion of the purchase, and, in return, shall be entitled to all debts and moneys owing to the Company, the latter reserving all pecuniary rights until the completion of the purchase. The engineer of the Company (Mr. A. Bromley Holmes) and all other officers and servants (excluding the Directors and solicitors) shall, unless any servant should desire otherwise, be taken over by the Corporation on the same terms as to position and emoluments as if he were continuing in the employ of the Company. The agreement is, of course, made subject to the approval of Parliament and to confirmation by the shareholders, and to such alteration as either House of Parliament may think fit to make therein, a proviso being made that should these alterations be by either party considered against their interests, it is in their option to withdraw from the agreement. An arbitration clause completes the document. The agreement refers not only to the Company's undertaking in the City but to the Toxteth Park scheme also. The following table shows the development of the Company's undertaking during the last five years :—

Year.	No. of lamps on December 31st.	Sales of electricity.	Profit before deducting depreciation.
1890	11,752	£13,343	£7,792
1891	14,966	£20,123	£11,760
1892	20,254	£25,515	£16,751
1893	25,784	£27,258	£17,507
1894	31,792	£31,352	£20,908

In presenting this report Mr. Alderman F. Smith, Chairman of the Electric Lighting Committee, said the price of £425,000 might appear extremely high, but, all circumstances being taken into account, the purchase was most desirable. The lighting of a city like Liverpool was a very important matter, and it was essential that it should be intelligently carried on from the point of view solely of the public interest. The future of the undertaking in the hands of the Corporation depended entirely upon the manner in which it was handled for the public benefit. Sir A. B. Forwood, M.P., contended that the arrangement was an improvident one, but admitted that there would probably be a large extension of the use of electric current in the future. He, however, approved of the work being in the hands of a private company. He also thought they might have made a better bargain. Mr. Ald. Bowring took strong exception to Sir A. B. Forwood's remarks, and pointed to the bargain made with the gas company which proved the most unfortunate the city had ever made. If they had had the foresight to acquire the gas undertaking it would have been an excellent proceeding for the community. Other speakers followed, cordially approving the action of the Committee, whose report was adopted.

Digitized by Google

LONGTON (STAFFS.).—At the last meeting of the Town Council the draft of an agreement between the North Staffordshire Tramways Company and the Corporation, with reference to the alteration of the date when the Corporation could compulsorily purchase the tram lines from 8 years to 22 years, and to the sanctioning of the installation of electricity by overhead wires, was read, and, after a brief discussion, approved.

MANCHESTER.—The City Council have decided to purchase additional land in Dickinson-street for the purpose of enlarging their electric supply station. It is intended to duplicate the plant at the generating station, and as this would take up all their present space, they were compelled to buy more land for storage purposes and possible future extension.

NORTHWICH.—The Lighting Committee of the District Council have considered the recent proposals of Mr. W. M. Beckett, of Manchester, for supplying electric current to this district, and they recommend the Council to inform Mr. Beckett that they were not at present disposed to take up the electric lighting question, but if a syndicate were formed to obtain a Provisional Order the Council would consider and discuss the terms of any proposal that might be made.

OSWESTRY.—The Oswestry Electric Light and Power Company will be in a position to supply electric current in the course of a few weeks. Satisfactory progress is, it is stated, being made with the erection of the plant at the Company's central station at Coney Green, and several large establishments in the town are being wired and fitted up for the electric light.

PERTH.—The Caledonian Electric Supply Company have notified the Town Council of their intention to apply for a Provisional Order. The Town Clerk pointed out that the notice was too late, and that the Council had hitherto opposed all proposals for the introduction of the electric light into the town, but he suggested that the Company should be allowed an opportunity of laying its terms before them, and this course was agreed to.

PRIVATE HOUSE LIGHTING.—Messrs. Drake and Gorham have received instructions from Major Kearsley, of Stapeley House, to fit the electric light throughout the house and stables. The plant includes a Marshall engine and a D.P. accumulator set of latest type.——Melmerby Hall, Ripon, the residence of Mr. J. T. Pearson, is being fitted for the electric light by Messrs. S. Dixon and Son, of Boar-lane, Leeds, the plant consisting of a 7-H.P. Crossley oil engine and a set of E.P.S. accumulators. 150 lights are used.

RUGELEY.—The District Council recently discussed the lighting question at some length. The Lighting Committee reported that they had received the usual tender for lighting the street lamps from September to April, but they recommended that the gas company be asked to make a reduction in the present price of gas. Mr. Buttery thought they should get the town lighted electrically. The Lighting Committee are to further consider and report on the whole question.

ST. HELENS.—The Town Council propose to ask the Local Government Board to sanction the loan of £10,000 for electric light works.

ST. PANCRAS.—At the last meeting of the Vestry, the Finance Committee reported that they had been unable to obtain the loan of £75,000 for electric lighting and dust destructor purposes from the National Bank, but the London County Council had agreed to lend them £56,100 at 2¾ per cent. interest, the loan to be for varying periods. The Works Committee reported that they had been in communication with the Electricity Committee on the subject of sanctioning the laying of mains by the London Hydraulic Power Company for the service of business premises in Charlotte-street, to extend along Tottenham Court-road, Windmill-street, and across Charlotte-street; but the latter Committee, viewing the Hydraulic Power Company as possible competitors with their electricity works for the supply of motor power, recommended that leave be not given. Mr. Purchese (Chairman of the Works Committee) stated that he was in favour of the application, which he thought a reasonable one. The refusal was only carried by a majority of one in a small committee, and he understood that the Hydraulic Company would give an undertaking not to use their power to produce electric current. As Chairman of the Works Committee he had to move the resolution confirming the Committee's decision, although, personally, he thought so reasonable an application should be granted. Mr. Wetenhall moved an amendment that the application be acceded to. A discussion ensued, in the course of which Mr. Sweet (Chairman of the Electricity Committee) said that from the moment the Vestry had decided to adopt electricity it was well understood they should never allow any rival competitors for supplying motive power into St. Pancras, and he hoped that if the Vestry consented to the application, they would insist simply on a service pipe to certain premises, and would not allow the laying of a main. On the amendment being put to the vote, it was found that there were 32 for and 32 against. The Chairman, on being appealed to, gave his casting vote against the amendment, and the recommendation of the Works Committee, refusing the application, was therefore confirmed.—A proposal to wire the Vestry Hall and offices for the electric light has been postponed.

SUNDERLAND.—The Town Council have decided to increase the salary of their electrical engineer (Mr. C. S. Vesey Brown) by £60 per annum.

THEATRE LIGHTING.—The Grand Theatre, Leeds, is being installed for the electric light by Messrs. S. Dixon and Son, of Boar-lane. The fittings are stated to be very elaborate and specially designed.

WESTERN AUSTRALIA.—The telegraph service belonging to the Victorian Government Postal Department has been for some time past in a state of great muddle, owing possibly to a too rapid extension. Mr. H. W. Jenvey, electrician to the Victorian General Post Office, has recently been on an official visit to report on the telegraph and telephone services of Western Australia, and has notified Mr. Sholl, the Postmaster-General, that direct telegraphic communication between Derby, in Western Australia, with Cape York, the northernmost point of Australia, has been effected, the total distance being 7,207 miles. The experiment proved an unqualified success, and the two offices exchanged messages for an hour. This, Mr. Jenvey asserts, is unequalled in the history of telegraphy, the best previous record being that London has spoken on the wires with Kurrachee, in North-Western India, a distance of about 6,000 miles. Automatic repeaters were used at Roebourne, Hamelin Pool, Perth, Albany, Israelite, Eucla, Lincoln, Adelaide, Melbourne, Sydney, Brisbane, Rockhampton, Townsville, Bowen and Cardwell. The following are the distances:—Derby to Perth, 1,609 miles; Perth to Adelaide, 2,062 miles; Adelaide to Melbourne, 500 miles; Melbourne to Sydney, 570 miles; Sydney to Brisbane, 640 miles; and Brisbane to Cape York, 1,826 miles—total, 7,207 miles. The signals are stated to have worked, on the whole, satisfactorily.

WREXHAM.—The Board of Trade have written to the District Council asking for their observations upon a request from the Wrexham and District Electric Supply Company for a further extension of six months in which to comply with the conditions of their Provisional Order. The Council have decided not to oppose the application, on the understanding that this would be the last extension applied for.

COMPANIES' MEETINGS AND REPORTS.

Cuba Submarine Telegraph Company (Limited).

The forty-eighth ordinary general meeting of this Company was held at the offices, 58, Old Broad-street, on Wednesday, August 7, 1895, under the presidency of Mr. Charles W. Parish.

The SECRETARY (Mr. James Scott) having read the notice calling the meeting,

The CHAIRMAN said: I daresay, gentlemen, that you will, as usual, take the report as read. You have it in your hands. ("Agreed.") Before reverting to the accounts before us, I would like to refer to the great loss we have sustained in the death of our valued Chairman, Mr. Greenwood. Those of you who were present at our general meeting last February may have noticed that he seemed far from well. I think his strong devotion to his work and duties had somewhat overtaxed his strength, and he fell a victim, like many others, to influenza. I am sure that no Company ever had a keener man of business upon its Board, and we shall long miss his valuable advice. You will also notice that our colleague, Mr. Low, has retired from active service. He has been a most useful member of this Board, and had been connected with it since the foundation of our Company, nearly a quarter of a century ago. He wisely thought that he had some right now restfully to enjoy the good dividends it has earned. We have been fortunate in appointing Mr. Robert Kaye Gray and Mr. Alexander Graham Low to fill these vacancies. The former gentleman has great experience, and is well known in connection with cables, while Mr. Alexander Graham Low is as keen as his father was, and will doubtless make as good a Director. Now, gentlemen, if you will kindly take the accounts in your hands, and refer to page 5, you will notice that our traffic receipts mount up to the splendid total of £29,164, which compares with £23,188 for the first half of last year, and shows no less than £5,976 increase; but I would have you clearly to understand that this increase is quite abnormal, and almost entirely results from the unfortunate revolution which is now going on in Cuba. Many of the land lines at the eastern end of the island have been destroyed by one party or the other, and consequently senders of messages have been glad to avail themselves of the excellent and reliable service which our cables provide. As regards expenses there has been some increase to meet the present circumstances, the expenses for the half-year under review being, as you will notice, £6,118, as against £5,113 for the same period last year, or an increase of £1,005, but of this £188 was due to an income tax adjustment, leaving the actual working increase at £817, and when I explain to you that more than three-quarters of this amount is due to expenses at stations, and includes a hut for the cable ends at Santiago, and a house for the cable tank at Cienfuegos, I think you may be well satisfied with the accounts. We have thought it advisable to add £1,500, as you will notice, to the reserve against loss on deposits with

Digitized by Google

banks. Business has not improved as quickly as was expected in either South America or Australia, and it is our duty to be on the safe side. This £1,500, together with the proposed dividends, will absorb £10,900, while £3,539. 19s. 10d. remains as a balance to carry forward to the next account, and we are able to place £13,638. 10s. 5d. to the reserve fund. We are especially glad to be able to strengthen our reserve in this manner, for I must prepare you that a reduction in our rates appears very imminent. We have warned you of this from time to time, as you are aware, and we have staved it off as long as possible, but we do see it is now approaching, and it is most necessary that our financial position should be as strong as possible. I would only add that our cables have worked well, and are in excellent order. I will now, with your permission, propose—

"*That the report and accounts for the half-year ended June 30th last, now submitted, be received and adopted.*"

Mr. GEORGE KEITH: I beg to second that.

Mr. COCHRAN: I think you have somewhat anticipated an inquiry I was going to make, but I do not think you have quite covered the ground. I was not present in February last, when our meeting was presided over by our late Chairman, whose sudden death I, with all the members of the Board and the proprietors, deeply regret; but I find that Mr. Greenwood, in referring to the extra expenses incurred at that period on maintenance of land lines, spoke of an extra outlay of £600, which he led the meeting to believe, I think, as far as I can judge from the report, was the extent of the expense incurred. I find under that item that we have in the last two years increased, as you say, by something like £600. Now, that is £1,200 expended in two half-years. I think it surely wants some further explanation than that you have given why so very large a sum should be expended. Looking back for many years, I find that from £230 to £250 has been the average half-yearly expenditure under this head. You have named the very large increase in our working expenses. I believe that as far back as the year 1890, in reply to a question which I put to the Chairman, the latter then assured us that our expenses, as far as he could see, were not likely to increase. They were then £4,921, whereas they now mount up—for the past half-year—to £6,118. When you reply to these inquiries you will, perhaps, let the proprietors know whether the additional charge this half-year exhausts, as far as the Directors are able to judge, the special expenditure under the head of maintenance of land lines.

The CHAIRMAN: With respect to Mr. Cochran's remarks, I should like to say that a large proportion of the expenses he has spoken of is in connection with maintenance of land lines, and it would be impossible for me to give you any assurance as to how much that expenditure may be in the future. It is our first duty to maintain your property up to the highest pitch. In the previous half-year there was a considerable outlay under that head, which arose because certain land lines had to be replaced, while in the half-year under review certain alterations had to be made. We took advantage of Mr. Keith's presence there to move the shore-ends of one cable, and we brought the ends from one hut to another. It was an advantageous alteration, but it entailed considerable cost. The house for the cable tank was also an important matter. I can only assure you that we are watching these figures most carefully, and you may take it for granted, I think, that we shall not waste any money, and we will not spend more than is necessary. With your permission I will now put the resolution. Having submitted it in the usual way, he declared it carried unanimously. I have now to propose—

"*That the following dividends for the half-year be now declared on the shares of the Company, viz., at the rate of 10 per cent. per annum, subject to income tax, on the Preference shares; and 8 per cent. per annum, free of income tax, on the Ordinary shares, payable on and after to-morrow.*"

The motion was seconded by Mr. KEITH, and carried.

Mr. R. K. Gray was re-elected a director of the Company and Mr. John Gane as auditor, and a cordial vote of thanks to the Chairman and Directors terminated the proceedings.

Waterloo and City Railway Company.

The third half-yearly general meeting of the shareholders in this Company was held yesterday at Waterloo Station, under the presidency of Mr. Wyndham S. Portal.

The SECRETARY (Mr. Fred. J. Macaulay) having read the notice convening the meeting,

The CHAIRMAN said: I presume you will take the report as read. Since we met six months ago we have all been actively engaged in continuing the work of this railway. The result has been, of course, a very considerable increase in the capital expenditure—much in excess of the previous half-years. The outlay for works and for properties amounts to £47,256—that is, up to June 30th last, as compared with £2,626 up to December, 1894. In February last I had the satisfaction of informing the shareholders the progress that was being made, and that there was every prospect of still increased advancement, as it went on without any interruption of any kind. Since then, as we all know—although we are dealing with things underground—the frost, to which every railway chairman has referred at the present half-yearly meetings, occurred, and we were not exempt therefrom. The very severe weather prevailed for about three months of this half-year, and caused a total stoppage of your works for several weeks. We were also interrupted by the requirements of the Metropolitan District Railway Company, under whose line we have to pass, and that further delayed the work on the City side of the river. We have here the plan, which is before your Board every time they meet, and we thought it would be interesting to the shareholders to see it. The marks on it show the progress that has been made in each tunnel every time we meet. One represents the up tunnel and the other the down tunnel, and you see that they are going on very nearly *pari passu*. It is an extremely interesting diagram to study. All the difficulties arising in connection with crossing under the Metropolitan District Railway have been overcome, and the present rate of progress is, we are told by the engineers and contractors, satisfactory in every shape and form. The engineers' report states that good progress has been made with the tunnels, which have been driven entirely underneath the bed of the Thames and for a length of 300 yards on the Surrey side and 120 yards on the Middlesex side of the river, and that, up to June 30th last, 1,200 yards of single tunnel had been constructed. We have further detailed information from the engineers as to the progress made during the past six months, which may be interesting to the shareholders. I am quite sure you would like to hear it read. It is dated the 22nd July, and is signed by Mr. W. R. Galbraith and Mr. J. H. Greathead:—

"At the date of our half-yearly report, on January 4th, the position of matters was that the stage had been completed in the river, two shafts had been sunk, the four shields for driving the two tunnels in each direction had been fixed, and the up or westernmost tunnel had been actually commenced and driven 100 yards, but the down tunnel had not been begun. During the past six months all the shields have been brought into use, and good progress has been made in both tunnels. Commencing in the river and driving in each direction, the tunnels have passed entirely beneath the bed of the Thames, and towards the City have been carried under the Thames Embankment wall, the Metropolitan District Railway, and the complication of sewers and subways which are concentrated at that point. Towards Waterloo the tunnels have also made good progress, and have passed underneath the whole of the buildings situated between the south side of the Thames and Stamford-street, and are now being driven under the roadway of the street. The total length of single tunnel driven during the six months is about 1,200 yards, the total contract length apart from station work being 4,400 yards. Satisfactory as the above is, better progress would have been made had it not been that questions arose with the Metropolitan District Railway Company, causing a delay of more than two months; but these differences have been satisfactorily adjusted. Tunnels have, however, now successfully cleared the Metropolitan District Railway, the air locks have been removed, and the tunnels are being driven forward in the ordinary way. Towards Waterloo one of the tunnels has always been wholly in the clay, but the down or westernmost tunnel touched the gravel near Hatfield-street; but all appliances for the application of compressed air being ready, it was at once brought into use, and found to be perfectly effective, as the water was held back, and none of it came into the tunnel. The works generally are in a very satisfactory state, and there is nothing apparently to prevent the tunnels being driven at full speed towards the Mansion House, the borings having disclosed an ample cover of solid London clay in that direction. Towards Waterloo both tunnels have cleared the buildings between Stamford-street and the river, and will be driven wholly under the street without interference with private property until they reach a point a little eastward of the Waterloo Bridge-road. The operations towards Waterloo will presently not be so easy as those towards the City, as we shall in the course of the next two months undoubtedly not only touch, but have to drive through, water-bearing strata; but ample machinery has been provided for an abundant supply of compressed air, which will be employed as soon as it is necessary. As regards the construction of the line under private property, we are glad to say that we have been unable to detect any damage whatever to the buildings underneath which we have passed. As electrical traction will be used on this railway for the haulage of the trains, it may be interesting to note that the contractors have now two electric locomotives at work, one in each tunnel, and that they convey the waggons from near the working faces to the shafts with expedition, and have given every satisfaction."

I should state that the negotiations with the District Railway Company did not retard our operations more than one week, and every assistance and fairness was shown to us in the matter by that Company. It is only right and just that we should state this. They were, of course, obliged to protect their own interests and take precautions which were only fair and reasonable as regards their own line; but they gave us all the help they fairly could. With respect to the terminals, negotiations are going on with the South-Western Railway Company as regards the Waterloo terminus; and the arrangements for the City terminus are still under discussion with the Central London Railway Company. There seems every appearance of our being able to come to a satisfactory conclusion of this matter, and that the contractors will be able to proceed with the work satisfactorily. I may just touch on the accounts, and state that the balance to the credit of capital account of £80,085 includes the sum of £32,500, received previously to the closing of our books on June 30th, on account of calls payable on July 1st. Without this the balance at credit would have been £47,585. I may mention that, with respect to the call lately made, the whole amount has recently been received, and will appear in the current half-year's accounts. The capital expenditure to June, 1895, is given in detail in table No. 5. The item of £2,589 for land and compensation represents the payments made for easements under properties and certain houses acquired by the Company. The next item, of £44,666, is for construction of way and stations, including engineering (£1,900). The item to credit—£466. 19s. 11d.—under the head of "Interest and commission," represents what we have received in dividends for our parliamentary deposit and interest on money with our bank. The statement I have made to you is to our mind in every way satisfactory and healthy looking. I may say that the number of our shareholders has increased to 541, against 494 the last time we met, and on the whole they rank rather highly, for they hold on the average nearly £1,000 each. It only remains to me now to congratulate you on the present prospects of the railway, and I am sure I may be allowed to congratulate the engineers, Messrs. Galbraith and Greathead, as well as the contractors, Messrs. Mowlem, Burt and Co., on the comparatively few difficulties they have had and the great hopes they

Digitized by Google

entertain that there will be nothing amounting to any real difficulty in the completion of this line. I now beg to move—

"*That the report of the Directors and statement of accounts to June 30, 1895, be and the same are hereby received and adopted.*"

The DEPUTY-CHAIRMAN (Lieut.-Col. the Hon. H. W. Campbell) seconded the motion.

The CHAIRMAN, in answer to a question from Mr. Beavis, said: We shall not be able to accommodate the shareholders in the way proposed, for one simple reason: that we do not want the money. A large sum might come in and we should not want it; and we shall therefore adhere to an interval of not less than two months between each call.

Mr. BEAVIS inquired the meaning of the entry in the No. 2 account, "Amount uncalled, less paid in advance."

The CHAIRMAN: That was paid in anticipation of calls, but no interest is paid on the amount.

The motion was then unanimously adopted, and the proceedings terminated.

Crompton and Co. (Limited).

The following is the full text of the report of the Directors of this Company, which was abstracted in our last issue. The general meeting takes place at the Cannon-street Hotel to-day (Friday) at 3 o'clock:—

The Company's business has again increased, but as will be seen from the statement of accounts to March 31st last accompanying the report the net profits show a considerable falling off in consequence of the further reductions in prices forced upon the Company. It is satisfactory to state that the Company's order book is well filled, and the works are kept extremely busy, more so probably than at any previous time. The Directors consider that a much healthier tone prevails in the business of electrical manufacturing, and they hope that there will be now a steady advance to better prices and better profits. The new debentures offered for subscription in January last were subscribed for to the amount of £82,850, which has provided additional working capital, and enabled the Company to materially reduce bankers' loans.

With regard to the Company's cooking and heating department the Directors have, since March 31st, granted a licence for the manufacture and sale of these appliances in France, the Company receiving £1,000 for the privilege and a substantial royalty on all sales; negotiations are also in progress for granting licences for other foreign countries.

The net profits for the year amount to £6,953. 10s. 11d., and after providing for debenture interest and other payments there remains a net revenue balance of £2,343. 15s. 9d., from which the Directors propose to set aside £1,000 for contingencies and doubtful debts, and to carry the balance £1,343. 15s. 9d. forward. They further propose to transfer the sum of £1,000 from the reserve fund in reduction of the preliminary expenses account.

The seven years fixed by the purchase agreement of July 16, 1888, during which the Company secured the right to the services of Mr. R. E. Crompton and Mr. J. F. Albright as Managing Directors, having expired, the Board have made arrangements for a continuance of their services.

Mr. H. H. J. W. Drummond has resigned his seat on the Board of Directors; Mr. Bernard Gibson seeks re-election as a Director, as do Messrs. J. H. Duncan and Co. as auditors.

NEW COMPANIES, STATUTORY RETURNS, &c.

PHŒBUS ELECTRIC BATTERY SYNDICATE (LIMITED).—This Company was registered on July 30th, with a capital of £3,000, in £1 shares, to carry into effect an agreement for the acquisition of certain inventions in relation to primary electric batteries, to construct, lay down, establish and carry out all necessary works, lines, batteries, accumulators, lamps and cables, and to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity for the purposes of light, heat and motive power, electrical apparatus manufacturers, manufacturing chemists, and the general business of an electric light company in all its branches. The subscribers, with one share each, are: A. Gianella, V. Guidotti, R. Maldifassi, E. Pellas, C. N. Ganzentes, M. Cizzio, and Ernest Lovett.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED). — The annual return to May 26th has just been filed. The nominal capital of £1,300,000, in £10 shares, has been subscribed for and allotted, and the full amount has been called and paid.

CALLENDER'S BITUMEN TELEGRAPH AND WATERPROOF COMPANY (LIMITED).—The annual return to June 25th has been filed. Of a nominal capital of £80,000, in £10 shares, 6,500 have been taken up. Of these, 3,000 have been issued as fully paid, and the full amount has been paid on the remaining 3,500 shares.

CITY NOTES.

BULUWAYO WATERWORKS COMPANY (LIMITED).—At the statutory general meeting of the shareholders of this Company last week the Chairman (Mr. Jarvis) said that it might be regarded as rather a novel departure to begin lighting so young a town as Buluwayo with electricity, but, on consideration, he could only come to the conclusion that the cheapest means of lighting is by electricity if you have water-power. The Company had received a cablegram from Sir John Willoughby to the effect that he had made all necessary arrangements for the electric light plant. Under the terms of their concession the electric lighting works would have to be commenced by November 10th and completed by February 10th.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended August 4th were £804, against £849 in the corresponding week of 1894, a decrease of £45. The total receipts for the half-year amount to £4,224, against £4,306 in the corresponding period of 1894, a decrease of £82.

DIRECT SPANISH TELEGRAPH COMPANY.—The estimated traffic receipts of this Company for the month of July are £1,889, against £1,400 in the corresponding period of last year, an increase of £489.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of July amounted to £61,413, against £56,753 in the corresponding period last year, being an increase of £4,660.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of July amounted to £47,555, and to £42,873 in the corresponding period of last year, an increase of £4,682.

EDINBURGH STREET TRAMWAYS COMPANY (LIMITED).—At the ordinary general meeting of the shareholders of this Company, on Monday, Sheriff Vary Campbell, who presided, referred to the question of a change from animal to mechanical traction, and said Edinburgh seemed to indicate a preference for cables, but the Directors were by no means satisfied that cabling was the best system. On the contrary, they thought some form of electric traction would be much better. They were, however, dependent upon the choice made by Edinburgh, and if the Edinburgh Corporation chose the cable system the Edinburgh Company must follow it.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).—An extraordinary general meeting of this Company will be held at the Offices, Ediswan Buildings, Queen Street, London, E.C., on Friday, the 16th inst., at One o'clock, when the resolution, passed at the meeting held on the 29th ult., will be submitted for confirmation as a special resolution.

GAS LIGHT AND COKE COMPANY.—At the ordinary general meeting of this Company on Friday last, the Chairman (Col. W. T. Makins), in moving the adoption of the report, said that the quantity of gas sold during the past six months was 9,841,000,000ft. against 9,227,000,000ft. for the corresponding period of 1894, an increase of 614,000,000ft. Commenting on the question of the incandescent gas light, the Chairman said "it was largely taking the place of the electric light," and the shareholders would consequently be the gainers, although by this system rather less gas was consumed than by the ordinary burner. He hoped the County Council would give this system a consideration, as he contended they would get a more brilliant light from it than by electricity, and it might be rather cheaper. A feature of the half-year was the abolition of meter rentals, which benefited the consumers to the extent of £29,000. He thought they had been fully justified in that policy, but he thought it was undesirable to make any further reduction in the price of gas at present. The Chairman made no mention as to what reduction would have been made in the price of gas, nor as to how long consumers might have waited for the abolition of meter rents, if it had not been for the actual and potential competition of the electric light.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this Company for July amounted to £25,600, and from 1st January to 31st July to £174,800, against, in the corresponding months of 1893 and 1894, £156,800 and £155,400 respectively.

HOUSE-TO-HOUSE ELECTRIC LIGHTING SUPPLY COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend on the Preference shares for the half-year ended June 30th last at the rate of 7 per cent. per annum. The dividend is payable on the 26th inst. The transfer books of the Company will be closed from the 16th to the 26th inst. inclusive. This Company notify that Mr. W. C. Weir, late secretary, has ceased to occupy that position. Mr. Thos. J. Owens is at present performing the duties of the office.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 4th inst. amounted to £1,355. The amount for the corresponding week last year was £1,000. Increase, £355.—A special service of fast trains was run during the busiest part of Monday (Bank Holiday) at intervals of 2½ to 3 minutes, and 52,447 passengers were carried, which is the largest number ever carried on the railway in one day. During the day a train mileage of 2,628 miles was run.

SMELTING COMPANY OF AUSTRALIA (LIMITED).—During the week this Company invited applications for 250,000 £1 shares, payable 2s. 6d. on application, 2s. 6d. on allotment, and the balance as may be determined. The Company has been formed for the purpose of erecting metallurgical works for the treatment of sulphide and other ores at Lake Illawarra, near Sydney, New South Wales, and to acquire from the Camden Syndicate (Limited) certain properties and rights, and also the benefit of an agreement to grant the sole licence to use in the Colony of New South Wales the electrolytic process of Messrs. Siemens Brothers and Co. (Limited) for the production of metallic zinc, patents for which are to be obtained by Messrs. Siemens Brothers. The lists opened yesterday (Thursday), and will close at noon to-day (Friday) for both town and country.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have appointed Tuesday next, the 13th instant, a special settling day in 10,277 Ordinary shares (Nos. 1 to 10,277) of the Chelsea Electricity Supply Company (Limited), and have ordered the same to be quoted in the Official List.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended August 2nd, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £2,930.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the half-month ended July 31st are £1,830, as compared with £1,762 in the corresponding period of 1894, an increase of £68.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 900. [No. 18. Vol. XXXV.] FRIDAY, AUGUST 16, 1895. PRICE SIXPENCE.

NOTES.

By the casting vote of the Chairman the St. Pancras Vestry last week decided to pervert its administrative powers to the crushing out of a possible competitor with a commercial venture of its own—to wit, its electric supply system. The London Hydraulic Power Company sought permission to lay a pipe in order to work an already erected lift in Charlotte-street. This permission was refused at the instance of the Electricity and Highways Committees. The impropriety of this action is self-evident. It is to be hoped that, unless the St. Pancras Vestry is quickly shamed into a more broad-minded, public-spirited frame of mind, the legality of its veto will be tested. The cloven foot of electrical municipalisation has taken even less time than we anticipated to show itself.

If proof were wanting of the shortsightedness displayed in the matter of the salaries by many of the Municipal Authorities who have undertaken the supply of electric current, it would be found in the remarks made by Mr. Holder, the Chairman of the Hull Electric Lighting Committee, in announcing the resignation of Mr. A. H. Gibbings, who has recently been appointed Corporation electrical engineer at Bradford. Mr. Holder said that Mr. Gibbings' resignation had taken him quite by surprise, and he presumed that it was purely a question of remuneration. The resignation had taken place at a most disadvantageous time for the Committee, as they had plans and contracts in hand for new machinery, the specifications and all the details connected with which were prepared on suggestions from Mr. Gibbings. The Committee had now lost by resignation two electrical engineers, and it appeared to him (Mr. Holder) that the Corporation were not paying a sufficiently large salary to induce first-class men to retain the position. Awkward incidents like this will, we trust, hasten the day when the salaries of engineers in charge of municipal stations will be regulated with some regard to the work and responsibility imposed.

Some time ago the electric light was introduced into the composing rooms of the *Dundee Advertiser*. Inverted Crompton-Pochin arcs were adopted by the advice of Mr. Thomas Reid, of University College, eight of these lamps being used in the case-room alone. The electric light is also used in the proof-readers' boxes and in the literary and commercial departments, and experiments have been made in the machine and despatch rooms, which have proved so satisfactory that it is probable that the electric light will shortly be extended to these departments. Current is obtained from the Corporation mains. In some composing rooms objection has been taken to the electric light, but the compositors on the *Dundee Advertiser* are, we believe, very pleased with it. Unquestionably during the summer months the electric light is of great advantage in printing offices, but we fear that, during the winter, compositors, whose fingers are seriously affected by the cold, will, at any rate in the early hours of work, call for some means of procuring artificial warmth. Where the current is readily available proprietors of printing offices should be approached by wiring contractors with the object of inducing them to put down electric radiators, which have only to be tried to prove their great value from the point of view of healthiness and adaptability to special circumstances. As usually arranged, it is necessary with gas or hot-water apparatus, in order that the men working in the centre of the room may be warmed, to overheat the space round the walls; moreover, the air in a steam-heated composing room is painfully dry, unless the usually-neglected precaution of having open vessels well filled with water is observed. In any case, it is inexcusable to foul the air with the products of coal-gas combustion in order that a work-room may be properly warmed as well as properly lighted. The ideal arrangement would be electric lighting and electric radiators; the next best arrangement would be electric lighting and properly-arranged gas stoves. Insurance companies, we understand, do not encourage the use of gas-stoves in printing works, and are inclined to look askance at electric radiators generally; but, provided good work is put in, in neither case is there much justification for this timid attitude.

We would call the attention of our readers to an article on "A Graphical Method of Analysing Harmonic Curves," by Mr. E. Basil Wedmore, which we publish this week. The investigation of alternate-current waves has given a great impetus principally to the analysis of complex single-valued harmonic waves and curves; though this is by no means the only physical application where even a theoretical interest arises. The costliness of apparatus and instruments for mechanically analysing complex harmonics into their simple harmonic constituents is so great, that the majority of students

Digitized by Google

who wish to pursue this branch of research are compelled to adopt some more or less laborious and complicated geometrical process of analysis. Recently we have described several of these graphic processes; and now yet another is contributed by Mr. Wedmore. The sole material for the operation of Mr. Wedmore's method is a Cartesian curve representing one single cycle of the harmonic wave to be analysed. This curve is subdivided in equal strips parallel with the axis of the function, commonly denoted by y; and the superposition of these strips on the same base, with the algebraic addition of the ordinates, gives a resultant curve from which certain of the components of the harmonic wave have become eliminated. This subdivision resembles the use of a group-reagent in chemical analysis; since it separates out a family of harmonic components. The use of successive subdivisions, increasing by the series which is the prime numbers, gives a succession of these families of components. And, from the families the individual components themselves are to be separated out. Mr. Wedmore's method is no doubt capable of yielding good and useful results if great care is taken in drawing and superposing the curves; but it is a laborious process, and where there are many component harmonics to be isolated it is one that must take up a great deal of time.

The type of dynamo described by Prof. Elihu Thomson in the Paper which we reprint this week, is of interest as illustrating the capability of an armature to supply part or the whole of its working field. The Sayers dynamo has lately shown that this possibility can be practically utilised, and in the present case the result arrived at was the over-compounding of the dynamo, so that its terminal voltage rose considerably as the load was increased although there were no series coils. No novel method of commutation was involved, and the brushes were given a forward lead in the usual fashion. Prof. Thomson expressly disclaims any thought of applying the design to commercial practice; indeed, a dynamo, which in its action is bipolar, is given what is to all intents a four-pole field, and such an arrangement could hardly compete in economy with ordinary compounding coils unless the required rise of pressure was a very large percentage of the no-load volts. Two of the poles have no winding, and are entirely idle at no load, but when the armature supplies current and the brushes are given a forward lead, these unwound poles come into play as additional paths for useful magnetic lines. In the dynamo of which constructional details are given, the area of face presented by the unwound poles to the core was actually larger than that of the wound poles, yet the terminal volts which were 84 at no load did not rise to more than 104 at full load—a rise large indeed, but not unattainable by ordinary methods. The idea, however, suggests itself that a similar arrangement of unwound but smaller poles might be combined with a Sayers armature so as to give a reversing field which should automatically increase in strength in due proportion to an increasing armature current.

Mr. Addenbrooke has done good service by calling attention this week, in his article on "The Telephone in England," to the fact that the outdoor work of the telephone business in this country is not nearly so highly paid when compared with Continental countries as many believe, whilst the exchange operators are actually paid less. At the same time, it does not necessarily follow from this, even if we admit Mr. Addenbrooke's assumption as to the greater cheapness of telephone material in this country, that telephone lines can be erected and worked at practically the same cost in England as on the Continent. Money wages are not by any means a complete criterion of the cost of labour to the capitalist. We must also know something as to the "efficiency" of the labourer, and something as to general prices. Mr. Addenbrooke tells us there is "a general idea that an Englishman gets over the ground rather quicker" than a foreigner. We sincerely hope he does, but we do not know that he does. These general ideas as to the innate superiority of the British workman had no doubt a considerable basis of fact half a century or more ago, but we suspect they are nowadays for the most part as grave a delusion as that held by the Spaniards of to-day on the subject of their national greatness. However, be this as it may, Mr. Addenbrooke has pointed out the proper path to the indefatigable but inaccurate assailants of the National Telephone Company. He has proved that the money wages paid by the Company to be in many cases less, in most cases but little higher, than those paid on the Continent. It is for him or others to prove that the cost of erecting, maintaining and working a telephone system is in the same state, that the Continental concerns honestly pay their way, and something over; that the money paid for patents, experiments, and amalgamations was, at the time of payment, extravagant. Then, and not till then, will the National Telephone Company be convicted of wanton over-capitalisation and gross mismanagement, and deservedly condemned to lower its tariffs and further improve its service irrespective of its dividends. We should like nothing better than a good telephone service at a cheap rate, but we should like also to be able to accept it with a clear conscience.

Dr. v. Kowalski read a Paper on a new accumulator at the general meeting of the German Electrochemical Society lately held at Frankfort, and detailed its capabilities while only partially describing its construction. Such points as appear to be of interest are here transcribed. The frame consists of celluloid and an acid-resisting paper; the negative plate is of antimonial lead surrounded with oxides of lead and antimony; this is dipped in a solution, cautiously characterised as "an electrolyte," whereby great virtue is imparted to the coating of lead and antimony oxides. The electrode, after sojourning for one day in the magic bath, is fit for use, and is presumably opposed to another electrode possibly of similar nature; on general grounds it may be guessed that both electrodes are immersed in "an electrolyte." Nothing but morbid curiosity could desire fuller information. With regard to the capabilities of the new accumulator, it is stated that by repeated formation with a current of three amperes, an output of 20 ampere-hours per kilogramme of electrode is attained, rising to 25-27 when the formation is prolonged to eight days. When experimentally agitated to simulate the conditions

Digitized by Google

obtaining in an electric tram, the value falls to 17-18 ampere-hours, but the amount of detritus from the plates is inconsiderable. Dr. v. Kowalski considers that the new accumulator will prove particularly useful for tram propulsion and railway carriage lighting.

Personal.—We hear that the Order of the Eagle has been conferred upon Mr. Nikola Tesla by the Prince of Montenegro.

Salford.—The electric supply station of the Salford Corporation was formally opened by the Chairman of the Gas and Electric Lighting Committee last Wednesday week, the 7th inst.

Cable Interruptions:—

	Date of Interruption.
Accra-Kotonou	August 9th.
Accra-Lagos	August 12th.

Telegraphic Communication in the Congo.—Work has lately been completed on the first line of telegraph in the Congo—between Borna, in the Lower Congo, and Matadi, the starting point of the Congo Railway.

Electric Conductors of Aluminium.—The French Société Electro-Metallurgique has, it is stated, recently supplied to M. E. C. Grammont an electric conductor made of aluminium, to be used in an electric power transmission at the Plaine and Pont de Cherny works of M. Grammont.

Durham College of Science.—Complete courses of instruction in mechanical, marine, electrical and civil engineering, naval architecture, mining and metallurgy are given at this College. The session commences on September 23rd, and further particulars appear in our advertisement columns.

Electro-Chemistry in Switzerland.—A company has just been formed at Turgi, Switzerland, to be known as the Société Anonyme d'Electrochimie. The new concern will establish plant for the production of chlorate of potash according to an electrolytic method invented by Dr. F. Oettel, who will manage the new works.

The Private Letters of Sir W. F. Cooke.—It may interest our readers to know that the Queen has been pleased to accept a copy of the extracts from the private letters of the late Sir W. F. Cooke, relating to the invention and development of the electric telegraph, recently published by permission of the Institution of Electrical Engineers.

Deaths by Lightning.—At Billingham on Saturday last a man was killed by lightning while taking refuge in a brick-kiln.——On the same day at Alfriston, near Lewes, a carter and his wife, while walking home, were struck by lightning. The man was killed right out, but the woman was only rendered unconscious, and recovered after a time.——At Douglas, Isle of Man, on the same day, the Woodbourne Hotel was struck by lightning, and all the electric fittings were destroyed.

Chicago Exhibition.—The President of the United States has issued, under the authority of a special Act of Congress, a complimentary diploma to the commissioners of the countries which took part in the Chicago Exhibition. The representatives of Great Britain who have received these diplomas, which acknowledge "the grateful appreciation of the Government and people of the United States of America for their valued participation" in the Exhibition, are Sir Richard Webster and Sir Henry Trueman Wood, the chairman and secretary of the Royal Commission.

Electrical Communication with Lighthouses and Lightships.—The members of the Royal Commission on Electrical Communication to Lighthouses and Lightships started on a tour of inspection to Denmark and the Baltic on Tuesday, 13th inst. All the principal Danish lightships and lighthouses, both in the Baltic and North Sea, will be visited. The Post Office authorities have placed their cableship "The Monarch" at the disposal of the Commission for this tour. The Commission expect to return to England about Friday, 23rd inst.

Utilisation of Water Power on the Rhone.—The prize competition for the best scheme for the utilisation of the water-power of the Rhone at the Canal du Jonage, to the extent of 20,000 H.P., intended for transmission to Lyon, which was offered by the Société Lyonnaise des Forces Motrices du Rhône, has just been decided in favour of the Compagnie de l'Industrie Électrique of Geneva and Paris for the electrical part, and Escher, Wyss and Co., of Zurich, for the hydraulic part. The jury consisted of Profs. Ferraris, Gérard and Picou. It may be of interest to note that the two firms named obtained also first prizes in the Niagara competition.

Niagara.—Those of our readers who are interested in the utilisation of water power at Niagara will be glad to know that a special number of *Cassier's Magazine* is devoted entirely to an account of this scheme. Ten special articles describing the various sections of the work have been written by the men directly concerned. These articles are profusely illustrated, there being no less than 200 views and portraits, and scale drawings of machinery. In view of the emphatic support which the first vice-president of the Cataracts Construction Company, Mr. F. L. Stetson, has given (see *The Electrician*, August 9th, p. 480) to the claims of Prof. George Forbes in connection with the design of the Niagara plant, we are astonished to find that Prof. Forbes' portrait does not appear in this otherwise complete account of the Niagara enterprise, nor do we find any but the scantiest reference to him, the most important member of the consulting staff.

The Institution of Junior Engineers.—The annual summer meeting of this Institution, whose headquarters are in London, takes place from August 17th to 24th, the rendezvous being Belgium. The towns to be visited include Antwerp, where the municipal docks, M. Kryn's diamond-cutting works, and other places of interest will be opened to members' inspection. At Ghent, MM. Carel's engine works, M. de Hemptinne's cotton spinning works, and M. Van Houtte's nursery gardens will be seen; at Brussels, the electric lighting station; whilst at Liége the works of the Société Cockerill, the Vieille Montagne zinc works, the St. Leonard locomotive works, the Val St. Lambert glass works, the small arms factory, and the electric tramway installation will be visited. An excursion to Verviers, where the Chamber of Commerce will entertain the visitors, is arranged for the purpose of seeing works in connection with the woollen cloth industry. Here MM. Peltzer's works, and those of M. Duesberg-Delrez, La Vesdre, and M. Hauzeur Gerard Fils will be opened. A visit to the celebrated Gileppe Reservoir, from which Verviers receives its water supply, is also included in the programme.

Electric Traction in Chicago.—According to the *Western Electrician* the three principal tramway companies of Chicago will have, when the work under way is completed, as it will be in a few months, electric lines having a total "trackage" of 335 miles. To supply power to the car motors on these lines, engines and generators aggregating in capacity 27,500 H.P. have been or are about to be installed. In addition, the four elevated railway companies, which have in operation or under construction about 85 miles of track, are certain to make use of electric power. One already does so, another has just awarded the contract for electrical equipment, a third, under construction, was planned from the first as an electric line, while the fourth, the oldest of all, must replace its steam locomotives by electric motors to place it on a paying footing. The steam railway companies that handle the bulk of Chicago's enormous suburban passenger traffic are, according to our Chicago contemporary, also considering the advisability of substituting electric power for the existing steam service, and one or two have decided to do so. This change has been brought about within a period of three years. "Chicago was slow in adopting the electric railway, but once the decision was made the work was pushed with characteristic energy and vigour."

An Interesting Electric Power Transmission Plant.—The town of Carcassonne has enjoyed the advantages of an electric system of distribution since 1890. The generating house is situated close to the River Aude, some five miles from the town, and comprises two 100 H.P. turbines, driving two 2,000-volt alternators. The demand for current having increased, M. Sicre, the owner of the plant, constructed a sub-station in his works at Carcassonne, comprising an Oerlikon 50 H.P.

Digitized by Google

2,000-volt alternator and a continuous-current dynamo. The coupling connecting the alternator and dynamo is in the shape of a pulley, which can be geared to a 100 H.P. steam engine by means of a belt. Under ordinary circumstances one of the generators at the generating station drives the motor-alternator at Carcassonne, the dynamo charging a battery of accumulators, and furnishing them with a current at a pressure of 160 volts. During the evening this transmission is suspended, and the battery supplies current to a special installation of 500 glow lamps. In times of extra high or extra low water, the machines at the sub-station come to the assistance of the main generators, the 100 H.P. steam engine being brought into use to drive both the continuous-current dynamo and the alternator, the former supplying current at 110 volts to the circuit usually supplied by the accumulators, and the altrnator working inp arallel with the 2,000-volt alternators five miles off.

Refuse Destructors as Steam Generators.—Last week, at the meeting of the British Institute of Public Health, at Hull, Mr. E. Manville read a Paper entitled "Refuse Destructors as Applied to Electric Lighting Purposes," in which he stated that having experimented on a large scale with samples of ash-bin refuse, collected at a season when household fires were not much in use, he had found the refuse extremely rich in carbon indeed; when the unsorted refuse was burnt directly in a boiler it evaporated 3lb. of water from and at 212°F. In his opinion the steam required could be obtained from the burning of this refuse in a properly designed arrangement of destructor cells and boilers, if only one-third of the calorific value of the refuse was utilised in the boilers, due allowance being made for the complete combustion of the ash-bin refuse and its gases. Mr. Manville then went on to refer to the Shoreditch scheme of utilising a refuse destructor combined with Mr. Druitt Halpin's thermal storage system, in which he stated that pressures of 200lb. to the square inch would be used. Mr. W. Holder, of Hull; Mr. R. S. Roundthwaite, of Sunderland; and Mr. S. Beaman, of Warrington, agreed in thinking that there was no field for the refuse destructor in this connection in places where coal was reasonably cheap. Mr. Manville, in closing the discussion, said that he admitted that power could not be generated as cheaply in this way as with coal, but asked his audience to remember that if the refuse had to be burnt, whatever useful heat they could obtain from it was pure gain.

Brazil and Trinidad.—At a meeting of the Balloon Society, held last Wednesday evening, Senor Juan Sanchez-Villegas contributed a Paper entitled "Gleanings of the History of Brazil and Trinidad." Senor Sanchez-Villegas described Trinidad as a barren volcanic islet situated some 700 miles from the southern part of the Brazilian coast and occupied by sea birds and land crabs. In the year 1700 Capt. Halley, who afterwards became the celebrated astronomer Dr. Halley, took possession of the islet in the name of the English monarch, and made an unsuccessful effort to stock it with pigs and sheep. The islet then serving no purpose, it was soon afterwards left to the Portuguese, who perhaps had first discovered it. The recent action of the British in taking possession of it again had wounded the patriotism and the pride of the Brazilians and led them to give expression to their feelings in public demonstrations, but it was hoped that the matter would soon be satisfactorily ended through diplomatic channels. The object in view was to render our telegraphic communication with the southern countries of South America independent of Brazil, our only cables to these parts of the world now having their termini on on the northern coast of that country. By means of Trinidad as an intermediary station we might communicate with the Argentine Republic, Chili and Peru direct. A cable could also be laid between those countries and the Cape of Good Hope viâ Trinidad and St. Helena. The following bombastic resolution was then passed:—"That having regard to the unique and influential position of Great Britain in promoting the progress of humanity throughout the world, and the high character of the statesmanship by which her world-wide affairs are directed, it is desirable, in the interests of the nations at large, that she should retain possession of the island of Trinidad, as well as other convenient stations which are necessary and contributory to the fulfilment of her high mission; and when it is considered that Great Britain owns seven-eighths of the submarine cables of the world, and that she has invested capital therein to the amount of £300,000,000, the commanding importance of the matter as a practical necessity cannot be exaggerated."

Researches on the Electric Discharge of the Raia Torpedo.—At the meeting of the Académie des Sciences on the 15th inst., M. d'Arsonval communicated the main results of some investigations on the electric discharge of the Raia Torpedo, which he has recently been carrying out at the Maritime Zoological and Physiological Laboratory at Concarneau. M. d'Arsonval's main object was to obtain accurate electrical measurements, which he points out should throw light upon the intimate connection between the electric discharge of this fish and the discharge obtained from ordinary muscular contraction; the discharge of the electric organ being, in his view, nothing more than an exaggeration of the oscillations which are noticed when muscles are contracted. Two registering devices were employed. The first, which M. d'Arsonval calls a "galvanograph," was nothing more than a d'Arsonval-Deprez galvanometer, the suspended coil being wound on an aluminium bobbin and attached to the centre of the india-rubber membrane of a Marey air drum, this drum being connected by an india-rubber tube to a second and smaller magnifying drum, actuating a short lever which marked a smoked cylinder. M. d'Arsonval also employed a hot-wire instrument, consisting of a silver wire of about 0·1mm. in diameter and 40cm. to 50cm. long, stretched between two rigid supports. Connected to the centre of this suspended wire was a second wire, kept in tension by an india-rubber spring, and carrying a pointer moving over a recording cylinder. The fish to be experimented upon was placed in a vessel with a metallic bottom, containing sea-water to the depth of about 1cm. Two tinfoil electrodes having the same shape as the electric organs were applied to the fish above and below, being connected together at one end through a strip of tinfoil, and at the other through the measuring instruments; the upper electrode being negative and the lower positive. To provoke a discharge, the fins were lightly pinched. The tracings obtained on the "galvanograph" showed that the discharge was not continuous but consists of six to ten successive discharges at intervals of about $\frac{1}{100}$th of a second, the strongest discharge being the third. The current was always in the same direction, and the curves had precisely the same form as those obtained from muscular contraction. The mean duration of a discharge varied between $\frac{1}{10}$th and $\frac{1}{20}$th of a second, at a temperature of 19°C. From torpedos having a diameter of from 25cm. to 35cm., which had been kept in the laboratory tanks for a week, M. d'Arsonval obtained electromotive forces of from 8 to 17 volts and currents of from one to seven amperes. With a view of visibly showing to an audience the energy of this animal's electric discharge, M. d'Arsonval has experimented with four volt glow lamps taking one ampere. On pinching the animal a lamp of this kind is momentarily incandesced to white heat, and if the pinch is too severe the lamp is often burnt out. Under favourable conditions three such lamps can be placed in series and incandesced. The needle of a Deprez-Carpentier ammeter, the scale of which went up to five amperes, was frequently sent off the scale. If the electric organ is discharged through a small Ruhmkorff coil, Geissler tubes are illuminated. The two organs work synergetically and with the same intensity. The power of a discharge is soon exhausted. If only one half of the organ has been used, and a glow lamp is then connected with the other half, a powerful current is obtained, proving that voluntary nervous excitation is not sufficient to exhaust the organ, and that the electric discharge is produced in the organ itself and not in the nervous system. After five or ten minutes rest, the organ is as vigorous as ever. On placing a stethoscope on the organ during a discharge, a note was given corresponding to 100 vibrations per second, showing that the organ is a seat of vibration, as is the case with muscles during voluntary contraction. If two discharges are taken simultaneously from one half of the organ, one from the front end and one from the back, there is a lag of about $\frac{1}{25}$th of a second between them, that from the front leading. When at rest, no difference of potential can be discovered between the two halves of the organ.

MAGNETIC UNITS.

The following are letters received from Mr. Heaviside, the first being the one referred to on page 11 of Dr. Lodge's pamphlet,* already circulated to members of the British Association Committee on Electrical Standards :—

"Paignton, January 28, 1895.

"DEAR LODGE: I had some idea of marking your paper all through, in the way of simplifying it mainly, but I gave it up when you got immersed in the 4π muddle. You (the B. A. Committee I mean) are in a beautiful state of muddle by reason of refusing to complete your work properly. You cannot say you did not know you were wrong till after the 'legalisation'; you cannot put it on to International Conferences; you began it, and the blame is yours—all the more so from your refusal to put it right, or even to make the beginning of an attempt to put it right, by open admission of error, and recommendation of a revision, and by properly discussing it at your B. A. meetings and at Chicago. There is no way out of the muddle than by my radical cure, I believe. When practicians get to be a little more enlightened than they are, the B. A. system will be something for them to laugh at and damn, if it is not already. Even in pure theory, it has been the cause of much mischief, of which I could give examples in the theories of eminent men. Swinburne has suggested in *Nature* that I am very likely wrong in this matter. What is more suggestive is that Magnus Maclean, of Glasgow, who wrote on Units in the *Electrical Engineer* lately, had the assurance to dismiss my reform with the condemnation that my reasons were unwarranted. The geographical suggestiveness is obvious, though perhaps equally unwarranted. But then *you* are a rationalist, and so is FitzGerald, and Larmor, and perhaps many more. Perhaps a majority on the B. A. Committee are rationalists. Then why do they not do the proper thing, and complete their work properly? You cannot get out of the muddle in any other way.

"Voltage and gaussage. I dare say practicians will not like them. Gaussage especially. (Sausage?) I do not admire them myself *very* much, on account of the 'age,' but I took voltage as I found it, and extended the meaning. (How about voltation and gaussation?) Accepting these words voltage and gaussage, however (or others), it should be noted that they stand for E.M.F. and for M.M.F., *not* for falls of potential (electric or magnetic), because the latter are exceptional, and in fact often become meaningless and quite wrong. Practicians are quite up to circuitation; the E.M.F. in a circuit, for instance, is the sum of the elementary effective parts of the real electric force. I think, then, that they should speak of the gaussage or the voltage in a circuit, or along a line, or from *a* to *b*, &c.; not gaussfall, which I do not like at all.

"I think 'intensity of' may be dropped altogether. I maintain that **E** and **H** *are* forces, dynamically (generalised, of course); specify them as the electric force and the magnetic force, and you are all right, and dynamically sound. Their factors **D** and **B** in the energy density are the corresponding fluxes.

"I think your opening part could be simplified a good deal. After that, when you bring in 4π and 10^{-1} and $\frac{10}{4\pi}$, and so forth, I would not presume to criticise. I would rather not concern myself with such a bad job.

"About the meaning to be given to inductance, permeance, &c., when you take in iron, and *do not* keep to very small forces or small variations in big forces. Here the practical requirements of the practician have to be consulted undoubtedly, but if they are let alone they may do it in some way that they will be sorry for afterwards. The difficulty seems to me to be that there is no definite connection between H and B. In § 192 of 'Electromagnetic Theory' I have tried to indicate how we may perhaps come to a good magnetic theory, in which, however, it would be necessary to discriminate; thus, $\mathbf{H}=\mathbf{F}+\mathbf{h}$; **F** *only* to be free, such that the curl of **F** is the current density.

"But as regards the extended meaning of μ: suppose we do take a definite connection between **H** and **B**, ignoring hysteresis, and that we have

$$-\operatorname{curl}\mathbf{E}=\dot{\mathbf{B}}.$$

How put $\dot{\mathbf{B}}$ in terms of **H**? It seems to me that the best theoretical way would be

$$\dot{\mathbf{B}}=\frac{d\mathbf{B}}{d\mathbf{H}}\frac{d\mathbf{H}}{dt}=\mu\dot{\mathbf{H}},$$

so that $\mu=\frac{d\mathbf{B}}{d\mathbf{H}}$ and $\mathbf{B}=\int\mu\, d\mathbf{H}$. [Similarly $\mathbf{D}=\int c\, d\mathbf{E}$.] [This is like saying that the volumic heat capacity of a body is

$$c=\frac{d\mathrm{H}}{dv},\quad \text{so that}\quad \mathrm{H}=\int c\,dv,\quad \text{and}\quad \dot{\mathrm{H}}=c\frac{dv}{dt},$$

H being the heat per unit volume, v the temperature. It goes well in the diffusion of heat.]

"Then, similarly, we should have in a circuit, (N = total induction),

$$\mathrm{E}=\dot{\mathrm{N}}=\frac{d\mathrm{N}}{d\mathrm{C}}\frac{d\mathrm{C}}{dt}=\mathrm{L}\dot{\mathrm{C}};$$

so that $\mathrm{L}=\frac{d\mathrm{N}}{d\mathrm{C}}$ and $\mathrm{N}=\int \mathrm{L}\,d\mathrm{C}$. The activity $\mathbf{H}\dot{\mathbf{B}}$ per unit volume would give

$$\dot{\mathrm{T}}=\mathrm{H}\dot{\mathrm{B}},\qquad \text{or}\qquad \mathrm{T}=\int\mathrm{H}\,d\mathrm{B}$$
$$=\mathrm{H}\mu\dot{\mathrm{H}},\qquad =\int\mathrm{H}\frac{d\mathrm{B}}{d\mathrm{H}}d\mathrm{H}=\int\mu\mathrm{H}\,d\mathrm{H};$$

and by volume integration, we should get for a coil,

$$\dot{\mathrm{T}}=\mathrm{C}\dot{\mathrm{N}}=\mathrm{CL}\dot{\mathrm{C}},$$
$$\mathrm{T}=\int\mathrm{C}\frac{d\mathrm{N}}{dt}dt=\int\mathrm{C}d\mathrm{N}=\int\mathrm{CL}d\mathrm{C}.$$

"But whether this is likely to be convenient for the iron people, I would not presume to say. Perhaps they do not want any of these quasi-scientific ways of trying to represent facts which are not definite in themselves; *i.e.*, $d\mathrm{B}/d\mathrm{H}$ is not a mere function of H."

"Paignton, February 3, 1895.

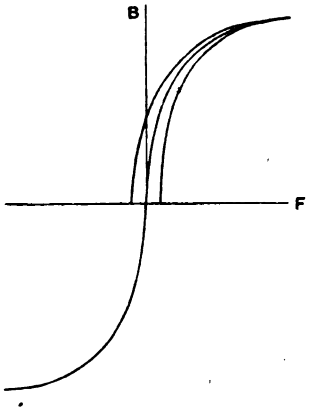
"DEAR LODGE: In my last, commenting on your report, I had doubts as to whether the $d\mathrm{B}/d\mathrm{H}=\mu$ definition would be convenient for practicians. It is obviously theoretically recommendative. On consideration, I again doubt it. Further than that, I do not think that quasi-official or conferential decisions are desirable on moot points involving unsettled theory. (That, however, is not a new opinion.) For the case is peculiar. There is no theory of magnetism, but only the beginnings of one. It is an excellent theory, too, only the application is limited. Now the effect of iron on the magnetic field is in general theory only a side matter, a secondary phenomenon, like many others. Commercially, it assumes exaggerated importance, so much so, that one is apt to overlook other and more important considerations in general theory. Practicians swallow camels in their 'predetermination' work. It is based on theory, in fact on the precise theory, but is modified empirically by characteristic curves, percentage allowances for waste by hysteresis and leakage (which is a big camel). They do their swallowing with complacency, so I suppose they do not suffer ill effects. If I were a practician, I would swallow camels too, if I found that they agreed with me, and sacrifice rigour to expediency. Not being a practician, though, I should very much like to see a good theory of magnetism with variable μ, and leave practicians to work any way they like, with fictitious make-believe permeances and reluctances, and lumping together of independent variables."

"Hysteresis is the theoretical trouble. Along with this, waste of energy. Now it is not enough to know how much waste there is in a cycle; I want to know how the waste comes in in different parts thereof, and on what it depends. Is it *invariably* associated with a change of the intrinsic magnetism (intrinsic *pro tem.*), or only accidentally, as a secondary matter? There is a curious case in last week's *Electrical Engineer*, in a paper by Mavor. The stuff is *called* steel, but is said to be chemically

* See *The Electrician*, August 2nd, p. 449, *et seq.*

Digitized by Google

pure iron. It gives relatively small waste, but large hysteresis, and large μ in the ordinary sense. Say as in the figure. It is imaginable that *quite* pure iron would make the loop become of insensible area. As it is, it is suggested to ignore the loop, and take the median curve; but if we do that we have B vanishing with H, a regular $\mu = dB/dH$ system, with energy stored and no waste. But owing to the extreme steepness of the curves we see that there is very large intrinsic B when H is zero or small, and this will be so even when the loop is made of smaller and smaller area. It seems quite absurd to take B/F to represent permeability, or dB/dF either. Here F is what the practicians call H; it belongs to the coil; curl $\mathbf{F} = \mathbf{C}$; not curl $\mathbf{H}$. But say $\mathbf{H} = \mathbf{h} + \mathbf{F}$, so that curl $(\mathbf{H} - \mathbf{h}) = $ curl $\mathbf{F} = \mathbf{C}$. We *must* allow for distinction between $\mathbf{H}$ and $\mathbf{F}$ in theory. As B is not a function of F only, we must have *at least* one other variable quantity. Perhaps h would be enough for a practical theory under limitations. But we need to know how h varies with F, or how much of B at any moment is con-



nected with F and how much is independent *pro tem.* I think this is the right way to look at it, because, first, this way satisfies Poisson's old theory (greatly simplified in expression) of induced magnetisation, and also the more modern view of the same, induced and intrinsic together (intrinsic constant though) (also simplified in expression), and if h could be considered given (as a function of the time for instance) with a given connection between B and H, we should still have a workable theory, a generalisation of the present. But practically we do not have h as a given datum (constant or variable). It comes in through the action of F, and, it seems, not in a regular or constant way. For the symmetrical loop is only got after many reversals, putting the iron into a peculiar state. If there were no waste (or it were insensible), it might be the same, but I am inclined to think there must be waste in the initial settling, even if there is none finally (in a suggested pure iron).

"I should think Ewing ought to have the material at his disposal, and the proper realisation of the facts, to be able to discriminate between B total and intrinsic, and to get a sort of normal true inductivity curve (quite different from the commonly assumed) and so come to a sort of theory."

A GRAPHICAL METHOD OF ANALYSING HARMONIC CURVES.

BY E. BASIL WEDMORE.

For the application of this method it is only necessary that an accurate sketch be obtained of one complete period of the curve. The result of the analysis is to give the component sine curves, each in its relative position with respect to the original curve.

The principle of the method is as follows:—If N periods (N being = or > unity) of a given sine curve be taken, and divided into P equal parts, and the P parts superposed and added algebraically, then the result will be, first, zero, if N does not equal P or a multiple of P; or secondly, will be a curve of a periodicity equal to that of the original curve and of an amplitude equal to P times that of the original curve, if N does equal P or a multiple of P. Thus, in Fig. 1 we have four curves of various periodicities. The figure is divided into two parts (*i.e.*, P = 2), and in Fig. 2 the parts are superposed, Fig. 3 showing the result of the algebraical addition. Here it is seen that curves 1 and 3, having respectively 1 and 3 periods, have been reduced to zero, 1 and 3 not being = P, or a multiple of P, while 2 and 4, where N = respectively P and a multiple of P, have been reproduced with their amplitude doubled—*i.e.*, multiplied by P.

Now, it will be clear that if we take one complete period of a curve consisting of a combination of sine curves of various periodicities and amplitudes, and having divided it into P parts, we superpose and algebraically add them, we shall obtain a curve which, when divided in amplitude by P, will consist only of a combination of those curves whose periodicity as compared with the original curve = P, or a multiple of P, all

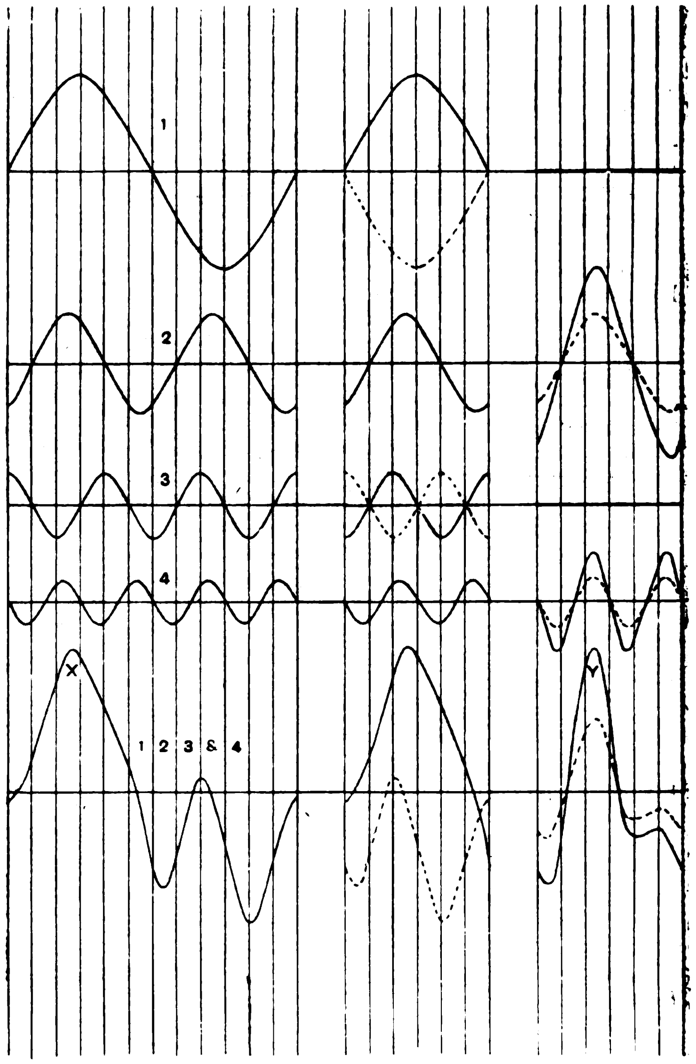


Fig. 1. Fig. 2. Fig. 3.

To show the Effect of Superposition on the various Components of a given Harmonic Curve.

other curves having become eliminated. Thus X in Fig. 1 is one period of a combination of curves having periodicities = 1, 2, 3, and 4 times that of X, and represented by curves Nos. 1, 2, 3, and 4. Curve X has been divided into two parts and the two parts superposed (*see* Fig. 2). The result is a curve Y (Fig. 3), which is seen to be composed only of curves 2 and 4, with their amplitude doubled. This is the first step in the analysis. If we reduce the amplitude of Y by half, and subtract it algebraically from X, we obviously obtain a curve composed only of curves 1 and 3.

Fig. 4 represents a complete analysis of the same curve. Here the dotted curves are superposed parts, the dot and dash

Digitized by Google

curves are curves as first obtained, the full line curves being the same, reduced in amplitude where necessary to their normal size. The curves are numbered in the order that they are obtained. Curve 2 is the same as Y, which we have already seen. Curve 3 = 2 reduced in amplitude, and represents a combination of curves having periodicities = 2, 4, 6, &c., times that of X. Curve 3 is bisected, and the two halves being superposed, we obtain 5, which being reduced by $\frac{1}{2}$ gives 6 = a sine curve having a periodicity = four times that of X, and is one of the components of X. Curves 7 and 8 are 3 and 1 superposed, the result of subtraction being 9, which represents a combination of curves of periodicities = 1, 3, 5, &c., times that of X. Curves 10 and 11 are 6 and 3 superposed, and subtraction gives us 12, another component. We now divide curve X into three parts and superpose the parts (13 and 14), curve 15 being the result, which divided by three gives us 16,

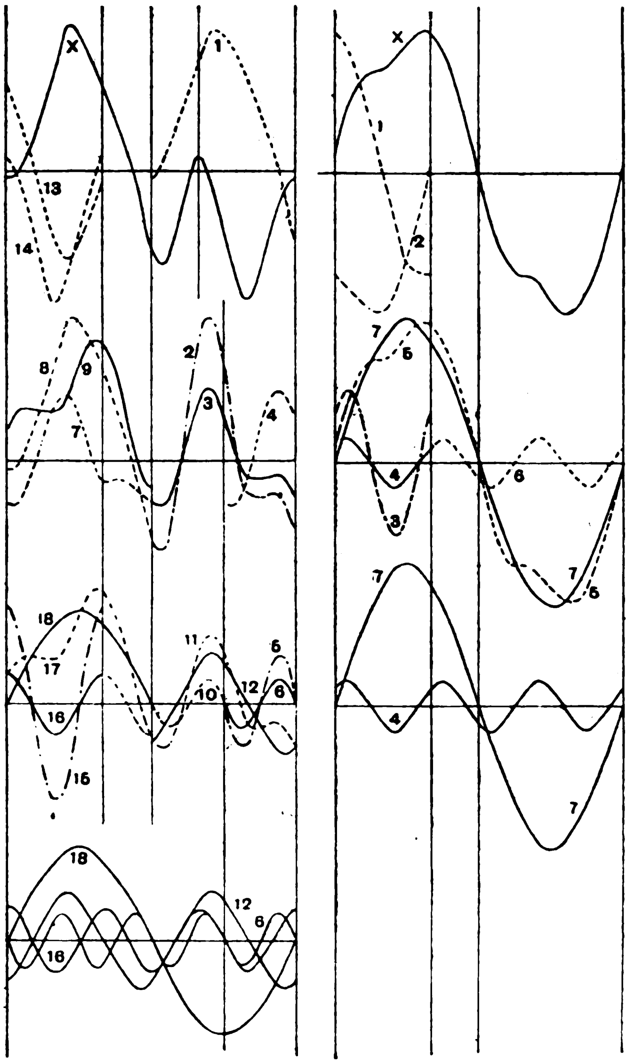

Fig. 4. Fig. 5.

The complete Analysis of the curves of two given Harmonics. Fig. 5 might be a Transformer Curve.

another component, which subtracted from 17 (17 = 9) gives us 18, the last component. For the sake of clearness, the four components 6, 12, 16 and 18 are reproduced at the bottom. It will be seen that they are the same in every respect as curves 1, 2, 3 and 4 (Fig. 1).

In the other example given (Fig. 5) it is obvious that if the curve were bisected and the parts superposed the result would be zero. Therefore there are no components with a periodicity = an even number as compared with X. We therefore divide into three parts, and proceed as before. If any residue remained unseparated we should next divide into five parts, *i.e.*, the next prime number.

THE TELEPHONE IN ENGLAND.

BY G. L. ADDENBROOKE.

During the course of the writer's preparation for the review of Mr. Bennett's work on the telephone systems of the Continent which appeared a short time since in this journal, some points were brought into prominence which did not appear to come within its scope, but which nevertheless appeared of importance. These were accordingly reserved, and a portion of them are now published, as they form an apt and fitting comment on the chairman's speech at the recent general meeting of the National Telephone Company.

Scattered through Mr. Bennett's book are the rates of wages paid in each country. It occurred to the writer to extract these in the form of a table. To these he has added the rates which are paid by the Telephone Company and Post Office in England. Mr. Bennett has himself kindly checked the table to see if it was a really fair statement to deduce from his figures. The English figures have also been seen by Mr. Preece at the Post Office, who expressed his general concurrence with them. That they represent fairly the National Company's wages the writer has also reason to know. It has been a little difficult to make a fair comparison because of dietary and other allowances given on the Continent and not in this country, but, if anything, the comparison is in favour of England.

The table has been got out in the form of shillings per week, neglecting fractions to admit of ready comparison.

Table showing Wages paid per week in Shillings.

Country.	Outdoor operatives. Foremen.	Wiremen.	Labourers.	Switch-room operatives.
Austria	28	20	16	8 to 10, to 14 in 3 years.
Belgium	32 to 40	14	11	8 to 16
Denmark	40	26	21	5·5, 4 hours, to 14·5, 6 hours.
Bavaria (Germany)	40	23	17	12, boys.
France, Paris	40*	30	...	12 to 20
France, Provinces	36	24	...	10 to 18
Holland	30 to 40	24	18	6·6 to 10
Norway & Sweden	27	20	15	11 to 19
Switzerland	30 to 36	22	15	15 when fully competent.
England, London	38 to 45	28 to 34	24	About 10 average.
England, Pr'vinces	27 to 42	23 to 26	20 to 23	About 9 average.

* And allowance.

Besides its bearing on the telephone industry this table has a wider interest, because the wages in telephony approximate in all cases to the wages paid for line work in telegraphy in all the countries, and these wages again are about the same to those paid in the allied electrical industries. These wages are therefore some indication to electrical engineers of the relative scales current in the chief countries on the Continent. It is only fair to remark also that the writer has good reason to believe that, with exception perhaps of Paris, house rent is cheaper all over the Continent than in England, and the price of commodities generally rather less. The foreign workman is therefore generally in rather a better position relatively to his English *confrère* than the figures show, while on the other hand there is, it is well known, a general idea that an Englishman gets over the ground rather quicker. When these matters are taken into account, it will be seen how closely the reward of labour, in this industry at any rate, approximates in this country. Belgium seems to form the most remarkable deviation.

Returning to telephony, the remarkable points about this table are that foreign wages for outdoor work approximate in many cases closely to English; while for switch-room operatives, who are mostly ladies, the wages paid abroad are, if anything, higher than our English rates. It is clear, therefore, that there is no argument from these items that English exchange subscription rates should be more than a slight percentage above foreign; since the labour in erecting lines is nearly as much abroad as in England, while the cost of operating—the real criterion, as it is a continual charge—is even less in England than on the Continent.

Digitized by Google

As regards the price of instruments and telephone material, they are pretty much the same everywhere, and, if anything, the advantage should lie with England.

The rates of annual subscription on the Continent and in England are as follows, the amounts being taken to the nearest shilling to make the table clearer and afford a readier means of comparison :—

——	Annual subscription.	Capital payment (if any).	Distance.
	Shillings.	£ s. d.	
Austria	*83*	4 3 4	500 metres [extra for extension]
Belgium—Antwerp	200	...	3 kilometres
Brussels	200	...	3 kilometres
General State rate, (double wires)	...	...	...
Denmark—Copenhagen	166	...	...
Provinces	40 to 90	...	..
Germany	151	...	5 kilometres
Holland—Amsterdam	195	...	...
Dordrecht	84	...	...
Breda	66	...	..
Hungary—Buda Pesth	250	...	...
Other towns	100	...	...
France—Paris	320	...	...
Lyons	240	...	...
Co-op. Societies	*40*	£8 to £10	...
Italy	160 to 56	...	...
Norway—Christiania	90	...	...
Provinces	66 to 28	..	...
Sweden—Companies	*111*	2 15 7	...
Government	*89*	2 15 7	...
Switzerland—First year	96	*	...
Second year	80	*	...
Third year	61	*	...
United Kingdom—London	400	...	...
London, Five years	340	...	...
London, Private residents	240	...	...
Principal towns	200	...	¾ mile.
Few small centres	180	...	...

If, then, from what has been said above, a telephone line can be erected nearly as cheaply in England as on the Continent, if the materials for the line and the instruments at the subscribers' end and at the exchange are the same price, and if the line, after it is erected, can be operated quite as cheaply in England as on the Continent, it is clear that there must be some other reasons why a satisfactory telephone service can be provided at so much cheaper rates in many cases on the Continent than the National Company allege is possible in England.

* 800 calls per annum, extra has to be paid on additional calls.

MOTIVE POWER AND GEARING.†

BY E. TREMLETT CARTER.

(*Continued from page 317.*)

The Steam Engine in Relation to Electric Power.

In the introduction the general conditions attending the working of electric power plant were summarised. Two distinct cases were shown to exist, viz. : (1) in electric lighting and power supply ; and (2) in electric traction. In the subsequent parts of this treatise the principles of steam plant have been discussed, and the behaviour of that plant under various conditions examined. We have seen under what conditions steam plant will work economically, and under what conditions it cannot be economical. We have also studied the various auxiliary apparatus by which its economical working may, under stated conditions, be improved. We have noted the relation of steam plant economy to such various considerations as : (1) the character of the fuel and of the water ; (2) the amount of load imposed on the plant; (3) the suitability of the plant, &c. We are now, therefore, in a position to enter upon a study of the relation of steam plant to the actual conditions met with in electric supply, in the two cases already named. In other words, we shall endeavour, in so far as it is possible on general grounds, to show in what ways the problem stated at the outset may be solved, when steam plant is used.

† From a forthcoming work to be published by *The Electrician* Printing and Publishing Company. All rights are reserved.

Electric Lighting and Power Supply.

In the case of electric light and power supply works we shall make the following principal considerations, viz.: as to (1) the total amount of boiler and engine power which it is good practice to provide ; (2) the subdivisions of these total boiler and engine plants ; (3) the influence of storage plant upon the foregoing considerations ; (4) the initial cost of these works ; and (5) the working costs.

Total Capacity of Plant.—In all these considerations we cannot do better than examine the state of affairs at the best and most modern of electric supply stations throughout the world, and note the advice given by the most experienced engineers in the matter. For in this matter, experience is everything : mere theorising is useless. Table XIX. presents at a glance the provisions made at some of the most important London and provincial stations, and also compares these provisions with the actual demand made upon the machinery. As far as has been possible, the author has endeavoured to avoid including stations which are so new that a fair proportion of the steady demand has not yet arisen. It will be seen that at many of the stations the ratio given in the last column is less than unity; and it will be observed that in the majority of cases these stations are provided with storage plant. The explanation is that by the use of electrical storage the generating plant has been able to work more throughout the period of low lamp demand than would otherwise be the case ; the factor of underloading of the plant is consequently reduced, which implies that the same total daily output can be obtained from a smaller plant.

Table XIX.*—*Mechanical Equipment and Capacity of Some London and Provincial Electric Supply Stations.*

Sheffield	2,000	1,250	20,726	22,000	1·061

It must be explained that the ratio given in the last column of Table XIX. covers the loss of power due to distribution over the network of mains. In many cases it would be found that when the power thus lost was deducted, there would be absolutely no surplus of engine power or of boiler power. Such stations depend for reserve plant upon a curious fact, which it will now be necessary to explain. Fig. 2 (Vol. XXXII., p. 159) shows a typical load diagram at a station of the kind we are now considering. Had this diagram been supplemented by a horizontal line indicating the total lamp capacity of the station, it would have been found that the irregular curve always lay far below that line. Even at the point of maximum demand, it is rarely if ever that the diagram approaches

* The data upon which this and subsequent Tables in this chapter have been compiled have been taken principally from "The Electrician" Electrical Trades' Directory and Handbook.

† These Stations are provided with electrical storage plant.

Digitized by Google

closely to the maximum possible demand. Many lamps are wired, but comparatively few are used at the same moment of time. The generating plant, if there is no storage, must be capable of coping with the total possible demand. As it never has to do so, the balance of power constitutes a sort of reserve. It cannot be said, however, that this is good practice; and the most experienced engineers recommend a reserve plant of from 20 to 25 per cent. in excess of the plant required for the maximum of actual work, when the station is properly filled up to the normal number of lamps.

Choice of Types.—Before passing on to consider the subdivision of the plant, a few words may be said in regard to the choice of a type of boiler or engine. Practice in this respect is very varied, but tends to run in grooves. In America slow-speed geared horizontal and vertical engines are largely in use, and water-tube boilers, mostly of the Babcock and Wilcox type. In Germany and France and other European countries, the direct-coupled slow-speed horizontal engine is most commonly met with; and the various water-tube boilers of Continental firms. In this country there are two distinct lines of practice—the metropolitan and the provincial. The former includes London and large cities; the latter represents the practice in small towns and villages. Table XX. shows the proportion of various types of boilers in London and in the provinces, this latter including all cities outside of London. It is interesting to note the preponderance of the compact water-tube boiler in London, and of the more bulky Lancashire boiler in the provinces. Here is evidently a competition between smokeless and bituminous coals, modified by considerations of the price of land and the cost of coal haulage. Table XXI. represents in a similar manner the London and provincial distribution of steam engines.

Subdivision of Plant.—It is only necessary to compare a typical load diagram with the diagrams representing the law of steam economy at various loads, to deduce that the supreme guiding principle in the choice of engines for electric supply stations must be, to provide that the engines which will be in use at any one time shall be as nearly fully loaded as possible. Ideally, an engine ought to be either fully loaded or not running. Thus much is conceded everywhere; but on the matter of the amount of subdivision opinions are divided. Evidently, however, the unit of plant is not so much fixed at a certain horse-power as at a certain *proportion* of the full horse-power. In a large station the unit will be larger than in a small station; but in every case it must be small enough to carry the station through the hours of minimum demand without the engine being very much underloaded. It is not necessary, nor does it occur in many of the best designed stations, that every item of plant shall be equal to the unit of plant. In this country the practice of having multiple units of plant is largely in vogue; in other countries, especially where subdivision is not carried to any great extent, it is not so common, though in all the large Continental and American stations single and multiple units generally are to be found. An idea of the amount of subdivision of the plant in British and foreign stations may be gathered from Table XXII. It is scarcely necessary to remark that to a great extent the choice of the type of engine and the amount of subdivision of the plant are dependent upon one another.

Initial Costs.—Some difficulty is unfortunately met with in an attempt to obtain extensive information regarding the

Digitized by Google

initial cost of plant, owing to the non-publication of and the reluctance of contractors to publish the exact amount of plant and work represented by the actual sum paid. As a rule the original sum tendered for is modified on account of subsequent changes in the plant. Table XXIII. will, however, furnish a fairly accurate guide to the actual costs of steam plant supplied for electric supply stations.

Working Expenses.—The actual expenses incurred, in running a large steam-driven electric supply station in the United Kingdom, are tabulated in Table XXIV. The data here given are based upon the annual accounts published by the various electrical concerns, and they are condensed from the large and comprehensive tables published with *The Electrician* of June 28 and August 9, 1895. It may be briefly remarked that all the items of expense are considerably above the lowest possible limit which would be reached if the plant could be worked under the most favourable conditions. Prof. Kennedy has stated, as recently as in July, 1895, that the actual load factors of steam engines in electric supply stations do not generally exceed 80 per cent., but vary from that figure down to as low as 55 per cent., only the time of running being counted.

Table XXIV.*—*Table showing the Working (Generating) Expenses at Steam Engine Electric Supply Stations in the United Kingdom for the year 1894.*

	—	Expenses in pence per Board of Trade unit.				
		Coal.	Oil and waste, &c.	Salaries and wages.	Repairs and maintenance.	Total working (generating) expenses.
Maxima.	Maximum of provincial companies	1·99	0·43	1·18	0·82	4·22
	Maximum of London companies	2·11	0·39	0·94	0·73	3·85

Total expenses		1·32

* The stations included in this table are those only which are included in the two supplements to *The Electrician* published on June 28 and August 9, 1895. All stations having a lower output than 100,000 units for the year are, therefore, excluded from the above data.

COMPOUNDING DYNAMOS FOR ARMATURE REACTION.*

BY ELIHU THOMSON.

Considerable attention has recently been drawn to the subject of means for counterbalancing or preventing armature reaction in dynamo generators or motors. The valuable Paper† of Messrs. H. J. Ryan and Milton F. Thompson, read before the Institute at its meeting on March 20th, called forth considerable discussion as to the actual utility or need of added devices, which undoubtedly render a machine more complex, but which can certainly be made to obliterate armature reaction or overcome its effects. The opinion which seems to prevail amongst engineers is that, by taking advantage of the best principles of design, the output of our machines is not limited by armature reaction, but rather by heating, or the capacity to diffuse that heat which is sure to be produced during operation. The writer's views are in accord with the general sentiment indicated by the discussion of the Paper in question, excepting that he conceives that it may on occasion become desirable to possess a structure, either generator or motor, in which a load which would inevitably overheat the machine if continuous, may be borne without destructive results for short periods only. The development of engineering work may in fact demand, occasionally, machines which would be regarded as emergency machines, to be operated with the highest possible loads for short periods. It is sometimes desirable that a dynamo be adapted to driving at different speeds while maintaining the same potential at the terminals, as in the case of direct-driven dynamos coupled with engines of different makes and speeds. Such an adaptation would require a change in the armature turns, or in the field excitation, the former demanding a reconstruction amounting to the production of a special type, while the latter, change of field strength, might involve such a weakened field at the higher speeds as would be incompatible with proper commutation. In such cases means and methods for securing proper commutation and neutralising reaction may become quite useful. The subject itself has been worked upon by the writer as far back as 1879. At first a peculiar disposition of the field coils and pole-pieces was selected, unfavourable to armature reactions, and later in a patent applied for by the writer in the year 1885, the series coil of a compound-wound machine was so disposed as to add, under load, a magneto-motive force to the field in the region of armature opposition, and as a consequence to diminish somewhat the magneto-motive force of the field where the reaction of the armature was positive or assisting. In the present Paper, however, the writer desires to bring to the attention of the Institute a different type of dynamo, worked upon by him some three or more years ago, in which there is no series winding whatever, though the machine is in effect compounded, or over-compounded at will. It is expressly to be understood at the outset that the present Paper is not intended to advocate the disposition described as a desirable commercial structure, or even as one which will be likely to come into practical use on any scale. On the contrary, it is believed to be open to objections which would take it out of competition with ordinary types, in which the compounding effect is secured by the series coil or load circuit wound, as usual, as a part of the field-energising conductor.

The machine is, however, interesting as bringing out forcibly the capability of the armature current to neutralise its own effects in a proper structure and maintain, or even increase, the potential at the brushes under heavy loads. In fact, the current in the armature in the type of machine herein treated is made to react under load to magnetise a portion of the field structure which at no load is neutral, or nearly so. The reaction may thus be made to give rise to a magnetic flux sufficient, or more than sufficient, to compensate for its effect in diminishing the flux of the other or excited portion. The result is accomplished by dividing each field pole into a portion which is left unwound and a portion which is wound and excited in shunt or separately. At no load only, the wound polar portions act to generate the open circuit E.M.F. As the load is put on, the unwound or dead poles become active, in consequence of a magnetic flux developed in them by the armature currents themselves—that is, in consequence of the M.M.F. generated by the current in the winding of the armature itself. The disposition of the poles in a bipolar structure would be represented by Fig. 1, where A A are the excited poles, or wound field cores, under the fringe of which commutation is effected, while D D are the "dead" poles or sections of polar surface unenergised at no load. A dotted line, *a a*, may pass through the neutral or non-polar portion of the armature iron, threaded by all field lines on one side, while the lines *b b* may indicate the diameter of commutation on which the brushes rest. In such a structure, by choosing the

* Paper read before the American Institute of Electrical Engineers at Niagara Falls, 1895.

† See *The Electrician*, April 19, 1895, p. 765.

Digitized by Google

position and spread of the "dead" poles in relation to that of the wound or excited polar portions, and adjusting the M.M.F. of the initial field relatively to the turns on the armature and the speed of driving, the effect of compounding or over-compounding may easily be obtained. The "dead poles" may be made adjustable in position so as to vary the effective M.M.F. of the armature upon them, and various changes in relations of the parts are conceivable.

In Figs. 2 and 3 an attempt has been made to represent the magnetic flux under no load and under load respectively. In Fig. 2 the flux in the air-gap between the excited poles A A and the armature may be considered as of uniform density, except at the edges, while in Fig. 3 it is, under the same poles, somewhat diminished towards the diameter of commutation. In Fig. 2 the dead poles are without flux across the air-gap, while in Fig. 3 the density increases from one edge to the other in the direction of rotation.

A dynamo constructed on this principle was multipolar, having four wound poles and four dead poles alternating in position around the armature. The latter was of standard iron projection type, being in fact identical in construction and dimensions with the armatures used about three years ago in regular four-pole dynamos of the marine type of the Thomson-Houston Electric Company.

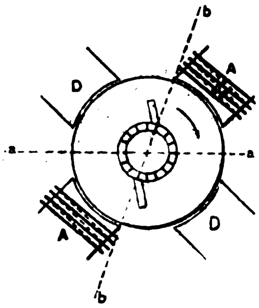

Fig. 1.

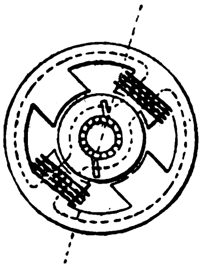

Fig. 2.

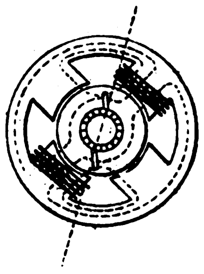

Fig. 3.

The principal data of the armature construction are as follows:—

Diameter over all	17 inches
Length (laminations)	8 „
Radial depth of laminations	4 „
No. of projections	87 „
Width of slots	0·34 inch
Depth of slots	0·75 „

The armature was series drum wound and had two conductors in each slot. The commutator had 87 segments. The new field system was constructed of two rings of cast open hearth steel having heavy lugs, four in number, projecting laterally from each ring on one side, and forming the dead poles when assembled in the machine. Separate castings for carrying the field coils and constituting the active poles were made, wound and bolted between the two ring castings of the field. The arrangement will be understood at a glance from an inspection of Figs. 4 and 5. Fig. 4 is a section of the field in a plane passing through the dead poles and the axis of the armature, and Fig. 5 is a similar section through the active or wound poles. The wound cores have a section of 3½in. × 8in. and are of steel. The field was bored to 17¼in., thus giving a clearance of ⅛in. around the armature. The excited or wound poles covered each about 5in., the dead poles each 5½in., leaving spaces between wound and dead poles of about 1½in. The face of each dead pole is 5½in. by 8in.

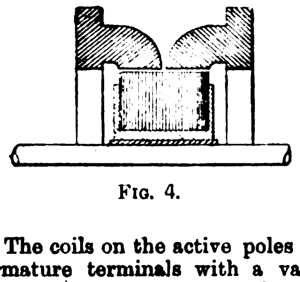

Fig. 4.

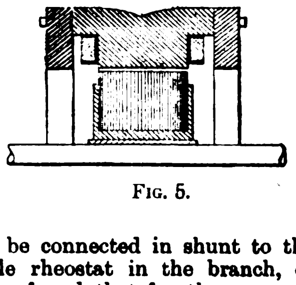

Fig. 5.

The coils on the active poles can be connected in shunt to the armature terminals with a variable rheostat in the branch, or separately excited as desired. It was found that for the purposes of test that the latter arrangement was most satisfactory, as the exciting current could then be adjusted to any given value, and would remain undisturbed by variations in the potential difference between the brushes or terminals of the machine.

Fig. 6 shows the relation of volts at the terminals to varying exciting current at no load (full line) and at 30 amperes load (dotted line) with a speed of 800 revolutions per minute. It will be noted that the load has caused an increase of voltage particularly at the relatively higher excitations. The normal current of full load for the armature, as constructed and used in the regular multipolar field, was 140 amperes, and it was found that as the load was increased steadily during a run, the potential was not only maintained but increased with each increment of load, thus showing an over-compounding effect. This effect was less marked when the initial excitation was weak, as when less than 3 amperes traversed the field coils. The over-compounding under load was, of course, still more increased when the field coils were connected in shunt to the armature. Thus, at a little over 750 revolutions per minute with an exciting current of four amperes, the open circuit volts were 84, rising to 104 when a load of 130 amperes was put on with an increase of the exciting current to 4·8 amperes.

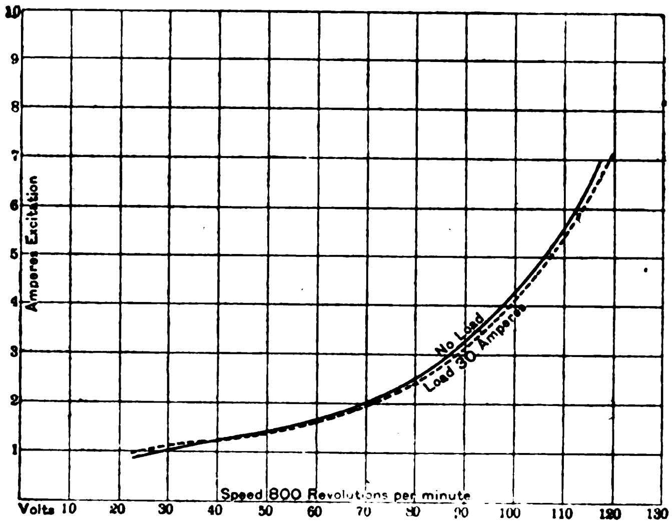

Fig. 6.

It was noticed that on any considerable increase of load being made, the potential rose in some cases as much as 5 or 6 volts above the point at which it would remain, or which it would reach after a short interval. Similarly it was found that the sudden taking off of load caused a temporary fall below the stable voltage under the new or diminished load conditions. This curious effect was traced to the difference of time between that needed to build up or cut down the flux in the dead poles, as compared with that required to cut down or build up the excited poles, which, being wound with wire, were naturally more sluggish under the conditions of use. Currents would be induced in the coils under each change of flux, which change itself would thereby be rendered more gradual. The dead poles being unwound could respond more rapidly. Any increase of load would, of course, tend to break down the wound poles and to increase the flux in the dead or unwound poles, and the taking off of load would have the opposite effect.

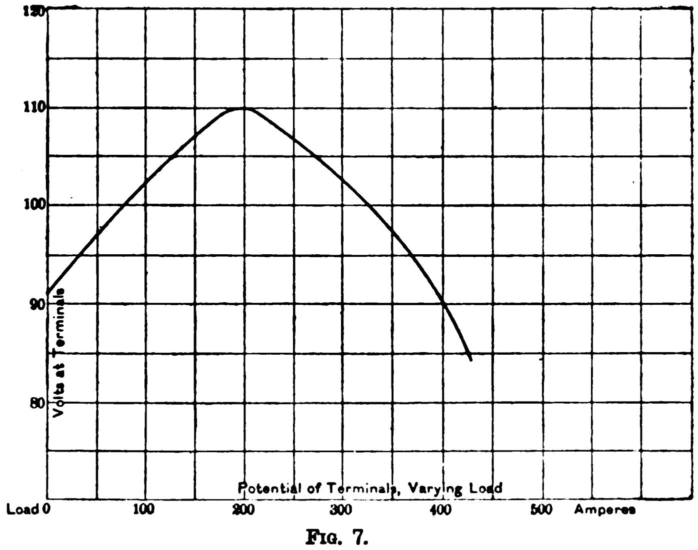

Fig. 7.

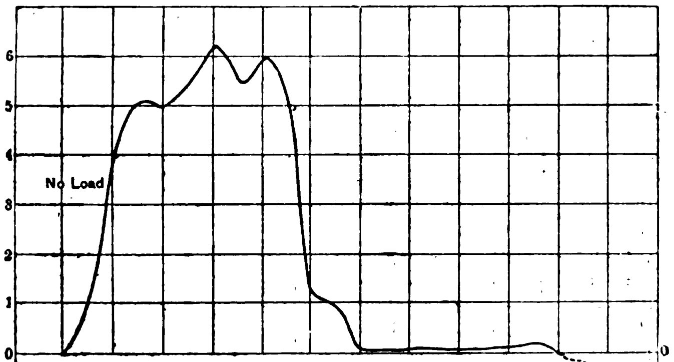
Fig. 7 shows a compounding curve obtained under a constant excitation of 4 amperes at a speed of 790 revolutions, the load being varied from 0 up to more than thrice the full load. It will be noticed that the potential at first increases, and only breaks down under extremes of load. The final breaking down is doubt-

Digitized by Google

less due to saturation of the forward portions of the dead poles, together with the armature core projections. Part of the drop was undoubtedly due to resistance at the brushes, which were of carbon, and by no means fitted to conduct off such heavy currents. Taking this drop and the drop over the armature conductor itself, it is not surprising that at the high loads the potential should fall off.

Fig. 8.



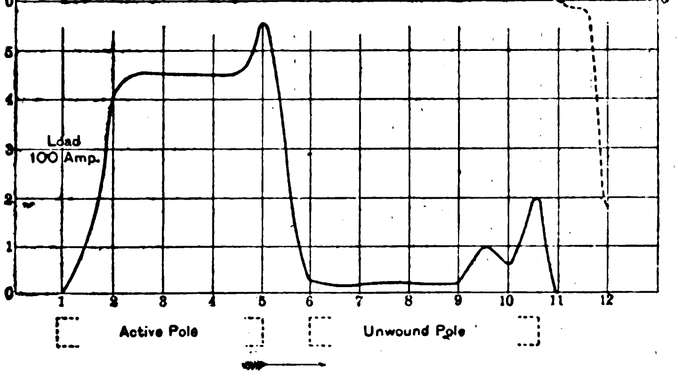


Fig. 9.

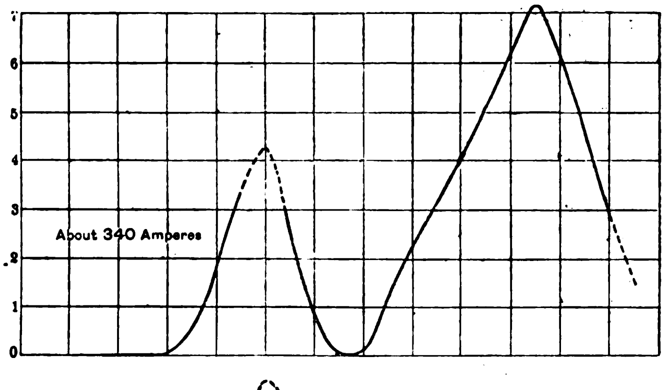
A horizontal plotting of the potentials generated in the armature coils under no load, obtained by the two-brush method of Dr. S. P. Thompson, is given in Fig. 8, the relative positions of the wound and "dead poles" being marked in dotted lines, and the arrow indi-

Fig. 10.



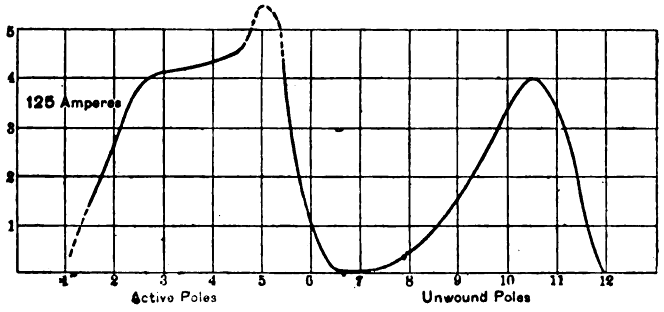


Fig. 11.

cating the direction of movement of the armature relatively thereto. Fig. 9 gives the same plotting under a load of 100 amperes, and accentuates the effect of the armature reaction in magnetising the dead poles. The curves are only approximate indications, owing to the fact that the number of points at which readings were taken was less than was desirable, and because in some cases it was difficult to maintain all conditions unchanged, particularly with the very heavy loads. Figs. 10 and 11 show a similar plotting for abnormal or extreme loads. The former shows how completely the wound pole has been broken down by armature reaction, and how the unwound poles have now become the chief working field poles, or rather how the armature winding itself has furnished the field for its own cutting. A calculation of the flux density at the forward edge of the unwound pole shows that the magnetisation has risen to saturation. The other parts of the pole are shown to be still susceptible of increase of flux, but their relation to the armature is far less favourable for its generation.

The machine described is probably chiefly interesting from a theoretical aspect. Still, it shows clearly that so far as the effect of the series field on compound-wound machines is concerned, the electrical engineer has other resources at his command giving similar results. It cannot be doubted also that the design of armature and field might be considerably improved with special regard for the particular feature of compounding. A feature of the machine which developed itself when carbon brushes were used, was that even at heavy loads the brushes could be set back from their maximum position, or true diameter of commutation in this case, and that the movement was attended with little, if any increase of spark, while the potential steadily went down. It was thus easily possible to adjust the potential by a backward movement of the brushes in the space between the unwound and wound poles, while the slight sparking under the carbon brushes was not increased thereby. The writer has never noticed this effect in so pronounced a degree in any other structures, but thinks that it may not be peculiar to this machine. A further interesting consideration is the effect of dispensing with the wound poles altogether, and either neglecting to employ any reversing or commutating field while maintaining the brushes near the forward edge of the field poles which now remain, namely, the unwound poles, or employing commutating arrangements similar to those used by Mr. Sayers, that is, returning the leads through slots in the armature under the strong induction of the forward edge of the pole as the armature leaves it. In such a case it would appear from theoretical considerations that the machine should, if it possessed any permanent magnetism, excite itself as a series dynamo entirely without any winding on the field and solely by the action of the armature winding itself. This fact was, I believe, first pointed out by Drs. J. and E. Hopkinson. In conclusion it may be stated that tests of the machine used to generate single-phase and three-phase alternating currents in its armature winding were made by dispensing with the commutator and substituting rings and connections common in such cases. The results indicated a substantially similar effect of compounding, but to a less degree, owing, no doubt, to the fact that the phase of the electromotive force generated by the wound pole flux would not coincide with that due to reaction on the dead poles, since the position of the poles with relation to any portion of the moving wire is different at the same instant.

THE NEW WESTINGHOUSE WORKS AT EAST PITTSBURG.

The Power Plant and Two-Phase System of Current Distribution.*

The power plant at East Pittsburg is almost identical with one that might be used for the supply of high-potential long-distance transmission circuits, but as all the energy generated at this plant is used within a few hundred yards of the station, the potential is restricted to only a few hundred volts. On account of the nearness of the points of distribution, polyphase currents have no advantages over the direct current in the way of transmission and distribution, but their superiority is quickly apparent when the simplicity and ease of handling the generators and motors is considered. A com parison, for example, of the direct and polyphase generators in the power house illustrates the point in question. Though the direct-current machines are of the most improved type, their commutators of necessity have daily required a certain amount of attention, while the polyphase machines have needed hardly a half-hour's care since they began operating some five or six months ago. Again, the motors require no starting box or controller when starting, as they are entirely self-contained, and it is only necessary to throw the short-circuit switch after they have gotten under way, in order to have them take up and carry their regular loads. The absence of commutators and starting boxes obviously makes the polyphase motors in every way preferable to direct-current machines for use by the average workman.

Another of the features in the operation of the East Pittsburg plant is the coupling of direct-connected alternators in multiple.

* Abstract from the *Electrical World* of New York, to whom we are also indebted for the blocks illustrating our abstract. For general description of these works see *The Electrician* of July 5th.

Digitized by Google

The power house is 206ft. in length by 76ft. wide. The building is of brick, resting on 16ft. stone foundations laid in concrete. All beams, girders, &c., are iron, and the roof of slate, so the building is completely fireproof. At present there are five batteries, each of 500 H.P., Pierpoint vertical water-pipe boilers. Steam is generated at 130lb. pressure, and is delivered through wrought-iron feeders equipped with Pratt and Cady valves to a 20in. main which runs along the west wall of the boiler house. The main passes into a 20in. Stratton steam separator, and is perhaps the largest separator ever made for low-pressure steam; the pipe then dips below the floor and passes up on the other side of the fire wall to the distributing pipes supplying the engines. The mains and steam pipes are all supported by roller bearings. The boilers are each fired by two Roney automatic stokers, fed with coal from cylindrical iron tanks suspended from the roof trusses. The stokers are all driven by a single Westinghouse standard 5 H.P. engine. The grates of the stoker form a series of steps, to which the coal is fed from the dead plate by a pusher having a vibratory motion; each step of the grates is given a rocking motion, the grate surface thus alternately forming a series of steps and an inclined plane with the grates partly overlapping like the shingles of a roof. In this manner the fuel is worked down, and at the same time broken up. The rocking motion is slow, being from 7 to 10 strokes per second, according to the kind of coal. Coal is brought to the power house by means of an elevated railway track, from which it is dropped through a shoot into bins located at the east end of the power house. On its way to the bins the coal passes through a crusher if necessary. From the bins the fuel is hoisted 60ft. by means of a chain-bucket elevator, which empties it into a conveyor that carries it to the tanks feeding the stokers. The capacity of each of these tanks is 8 tons, and the total capacity of the bins about 150 tons. A 15 H.P. electric motor drives the conveyor, and a 20 H.P. motor operates the lift and runs the crusher when required. The feed water for the boilers may be fed under reservoir pressure directly to the boilers, or run into the feed-water heater, from which it is forced into the boilers against pressure by means of duplex double-acting pumps. The pumps are each fitted with a counter, and there is also a water meter connected to the supply pipe, so that all water furnished the boilers is accurately measured. Part of the exhaust steam from the engine is used for supplying a Warren-Webster vacuum heater, which raises the temperature of the feed water to 200 to 210°F. Exhaust steam is also used for heating the buildings, and the condensed water from the radiators and heaters is returned to an elevated tank near the eaves of the boiler house by means of a Warren-Webster vacuum pump, which maintains from 10in. to 15in. vacuum on the heating system, thus relieving any back pressure on the engines. From the elevated tank the water flows by gravity into the feed-water heater, where the level is maintained by a float. When the returns of the heating system are insufficient to supply the demands, the float automatically admits cold water. There is also being put in the boiler house a 20in. by 12in. by 16in. Snow underwriters' high-pressure fire pump, which is to obtain its supply of water either from the city mains or from a large reservoir recently sunk just outside the power house. Furthermore, there are in the boiler room several Westinghouse air pumps for maintaining air pressure used in the manufacturing departments.

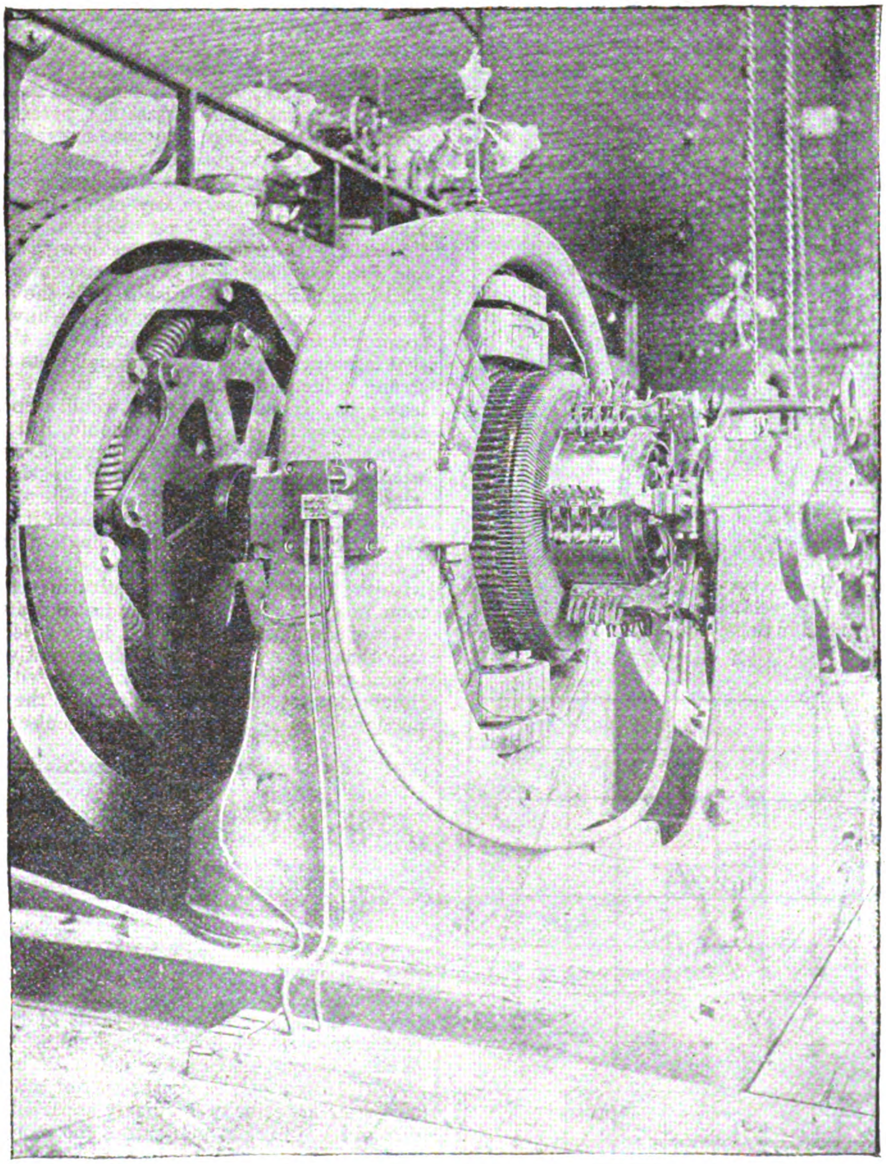

Fig. 1.—500 H.P. Direct-Connected D.C. Generator

The five engines already in operation are of the regulation Westinghouse compound type.

The dynamo room at the west end of the building is 76ft. by 70ft., and completely separated from the boiler room by an 8in. fire wall. The equipment consists of three 500 H.P. two-phase generators and two 500 H.P. direct-current machines, each connected to a 500 H.P. Westinghouse compound engine. These machines are already in

Digitized by Google

operation, and there is being erected an additional 500 H.P. direct-current generator, direct connected to a 500 H.P. steeple compound Westinghouse engine of a new type. Each of the generators rests on a bed-plate in common with its engine, to which it is direct connected by means of a flexible coupling. The space occupied by the steeple engine and its dynamo is only 17ft. by 8ft. 6in. ; the other five units occupy a space 22ft. by 8ft. 6in. There is also installed a revolving transformer, or two-phase motor, used for driving a direct-current arc lighting machine, and also for supplying the exciting current for the fields of the polyphase generators.

The direct-current generators (Fig. 1) are all of the Westinghouse standard type—that is, they have a slotted, ventilated armature and a cast-iron yoke with inwardly projecting pole-pieces of laminated steel. The general dimensions are 7ft. 10in. by 8ft. 8in. and 8ft. 3in. in height. The armature winding consists of bars of copper threaded through slots in the core, and so connected as to give a two-circuit winding, which at all times ensures equal distribution of current throughout the coils. The armature is 46in. in diameter, keyed and pressed to a 7in. shaft, which is 104½in. in length and 48⅞in. between journals. The commutator, 26in. in diameter, with a 10½in. face, is of the best grade copper, properly tempered, and built up with Canadian mica. The current is collected by means of a six-arm brush-holder carrying three carbon brushes per arm. The bearings have a spherical seat, so that they are at all times self-aligning. Below the bearings are large reservoirs for oil, which is carried up to the shaft by means of brass rings, thus affording automatic lubrication. The pole-pieces are built up of sheet steel punchings riveted together; thus constructed they are sent to the foundry and there have the yoke cast solidly about them. The lower half of the field yoke and the bearing supports are cast in one solid piece, thereby securing rigidity and strength. The field winding is, of course, compound, the series coils being copper strips of ¾in. cross-section. The machines develop 750 amperes at 500 volts when running at normal speed, which is 215 revolutions per minute. The points of commutation are constant under all loads, and the machines will carry, for short periods, as high as 75 per cent. over-load without damage or undue sparking.

The polyphase generators (Fig. 2) are of the same general form and dimensions as the direct-current generators. They have 14 laminated steel pole-pieces, built up and cast into the yoke in the same manner as described above. The exciting coils have but a single winding, as regulation is secured through a rotary transformer which supplies the total field current. The armature is very similar to the direct-current hub or spider, the whole design providing for thorough ventilation during operation. The periphery contains some 92 slots, in which the bar winding used is held in position by strips of rigid insulating material secured by grooves inside the slots. It is of the continuous type, and the four connections are brought out at points 90deg. from each other, to four collecting rings, where the current is collected by means of copper brushes. The collecting rings are 5½in. in diameter, with a 1½in. face. There are four brush-holder arms, two per circuit, which carry two brushes to each arm in order to ensure efficient contact. The polyphase machines run at the same speed as the direct generators—215 revolutions per minute. They generate current of 3,000 alternations (25 ∿) at a potential of 240 volts. Their normal output is 400 amperes on each of the two circuits. These generators are usually run in multiple, operating as perfectly and satisfactorily as any direct-current machines.

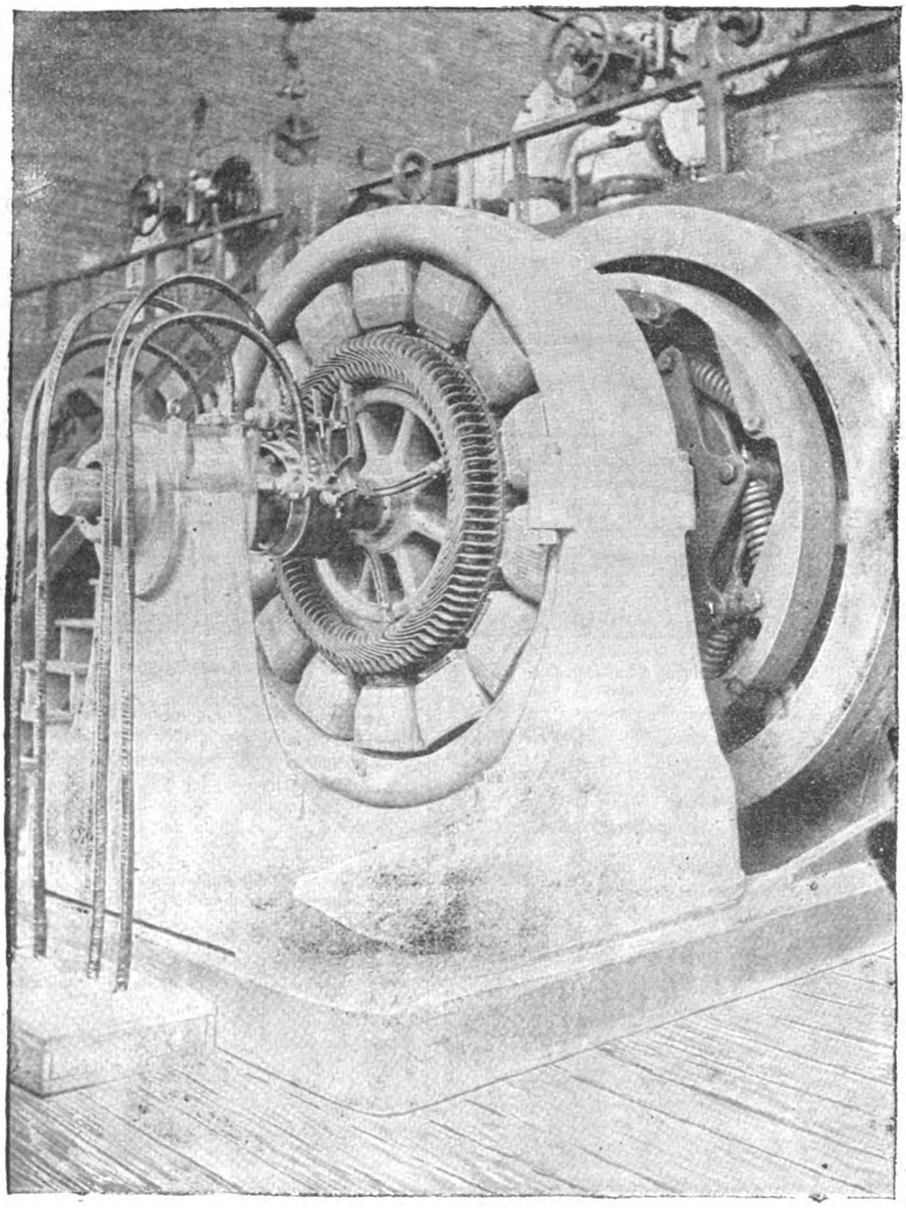

Fig. 2.—500H.P. Direct-Connected Two-Phase Generator.

Digitized by Google

At present there are installed two temporary switchboards, which will be replaced by handsome Italian marble incombustible boards, one for the direct-current and one for the polyphase system. These

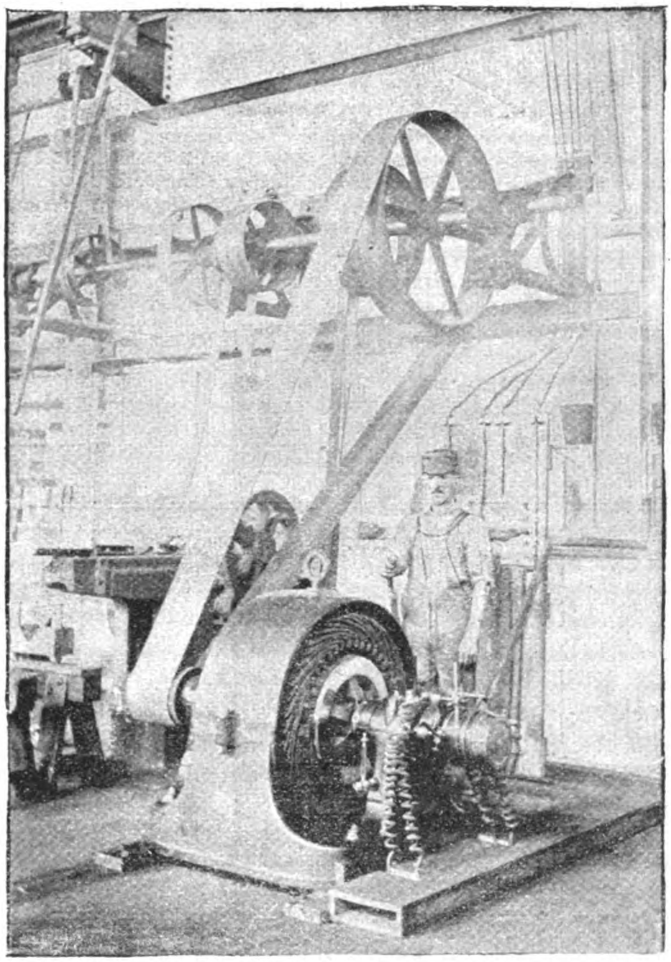

FIG. 3.—60 H.P. Two-Phase Motor Driving Shafting.

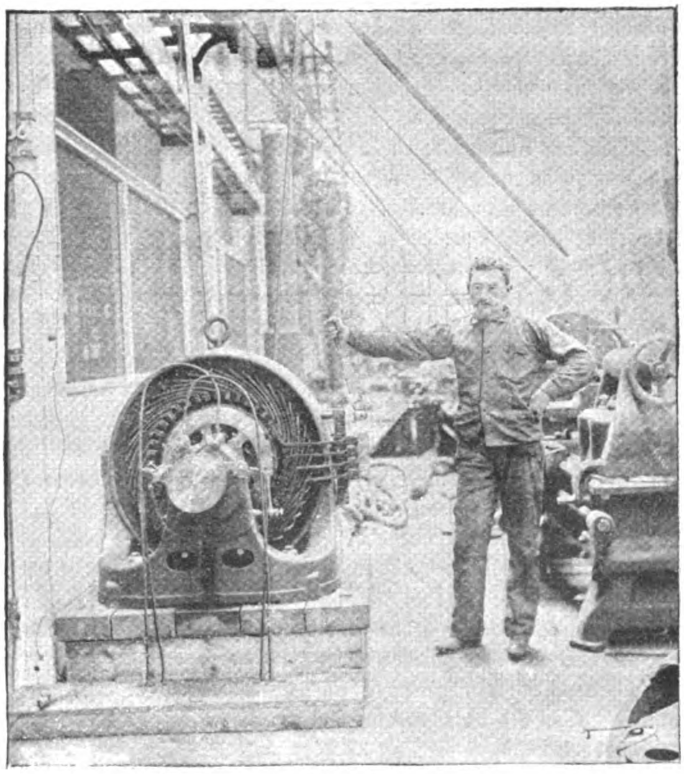

FIG. 4.—40 H.P. Two-Phase Motor Driving Shafting.

boards will be of a new and improved type, a single marble slab over 5ft. long, 2ft. wide, and $1\frac{1}{4}$in. thick, taking the place of a number of smaller units. The apparatus will be mounted directly on the face of the marbles, which will be supported by iron bracings against the wall. Each board will consist of one load, five generator and five feeder panels. The load panel will be equipped with wattmeters and voltmeters for measuring the total output of the machines in multiple. Each of the dynamo panels will contain signal lamps, main switches, voltmeter and ammeter switches, ammeters, rheostats, and synchroscopes or phase indicators on the polyphase board for throwing in multiple. The feeder panels will be equipped with lamps, ammeters, fuses or circuit breakers, switches, &c.

Up to the point at which the current leaves the switchboard for supplying the transmission circuits, the installation is identical with that which would be used for long distance work. If the energy were to be used, for example, at Johnstown, Pa., 75 miles distant, it would only be necessary to connect in converters and transform the potential from 240 to perhaps 10,000 or 15,000 volts. In the Westinghouse plant the current is distributed through copper cables covered with simple waterproof insulation. These are carried on heavy iron brackets. The wires are arranged to avoid mutual and self-inductive effects.

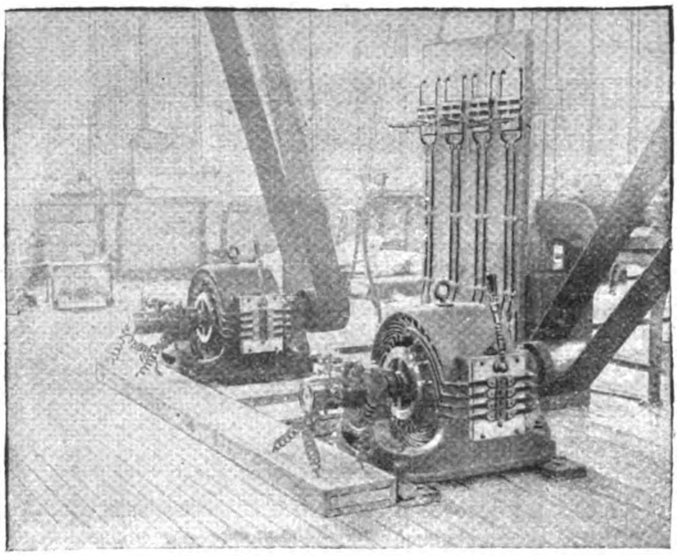

FIG. 5.—Two 30 H.P. Motors Driving Shafting.

As a rule the Tesla motors are belted, as shown in Figs. 3, 4 and 5, to short lengths of shafting from which the machinery is driven. The location of the motors and their horse-power is given in the appended table :—

220-volt Polyphase Motors.

Throughout the factory there are 17 electric, freight and passenger elevators which were at first operated by direct current; these are rapidly being replaced by multiphase motors. The elevators are all belt-driven, but there is no objection to their being direct connected whenever so desired. The motors vary from 20 to 30 H.P. capacity.

GRADUATION IN BUSINESS.

SOCRATES taught that the essence of knowledge is definition; and it has been said by more than one wise man in later times that the beginning of science, which is correlated knowledge, consists in measurement. Be all this as it may, it is certain that one of the earliest attempts of science or knowledge was to put a measure upon itself, to define the degree of success with which a votary may have mastered it. Indeed, long before science could claim to be "exact," in the modern meaning of the term, its students sought to proclaim their status by a series of carefully and exactly defined labels, commonly called degrees. In earliest times these degrees were few in kind, and they served rather to indicate the extent of a student's mental expansion than to represent his qualification for special practice. Nowadays, however, degrees are not only more numerous in kind, but there is distinct differentiation to be made between those of the ancient type and those which are a product of the latter-day utilitarian spirit. The former are the index of a man's education; the latter, the ostensible guarantee of his proficiency in some one or other line of business.

This important distinction between two classes of degrees, entirely opposite in their intention, is not always as carefully attended to as might be by authorities in educational matters. There is noticeable sometimes a tendency to give to the modern business degree that same wide latitude which is reasonable enough in degrees of a more purely ornamental character. When a man wishes to widen and deepen his general education by a course of study in the Arts, it matters little or nothing whether his mind is expanded by this or by that form of intellectual labour. To-day he may choose Latin and Greek; had he lived in ancient Athens he might with equal mental advantage have chosen Egyptian and Chaldean. But when it is the purpose of the man to practise the business of, say, administering drugs to his fellow man, the sublimest knowledge of the classics cannot compensate for ignorance of the effects of one single drug; or, if he intends to practise as a mining engineer, the utmost proficiency in chemical analysis cannot avail in place of a thorough knowledge of the practice of mining.

Digitized by Google

No doubt these things seem trite enough and perfectly obvious; yet our attention has recently been drawn to a "Prospectus of Elective Studies," issued by the Michigan Mining School, in which such trite and obvious things have been ignored. Far be it from us to seem to explain what is meant by "elective studies," when the exposition thereof fills a pamphlet of fifty pages, and is complicated enough to occupy the time of an intending student for the first month of his college tuition. But we cannot refrain from descanting upon one or two of the peculiarities of this elaborate educational device, which impressed us after we had successfully wrestled with the contents of the said pamphlet. In the first place, education at the Michigan Mining School is measured in terms of that *fin de siècle* thing, a unit. "The unit of the system is a study taken three times a week for 34 weeks"; which is very like making one *mauvais quart-d'heure* the unit of misery. That much settled, the next thing is to offer the student three degrees,—we will notice only one of these, viz., that of E.M., or Mining Engineer; and to affix the number of "units" which will qualify for a degree. There are numerous subjects, many not connected with mining, taught at the Michigan Mining School; and each is worth so many units, or fractions of a unit; and the game—for it is not unlike a species of game—is to "pass" in enough units to win a degree. To qualify as a Mining Engineer at the Michigan Mining School you must "pass in 22 full courses, including subjects 20 and 21," which means that you must get 22 units anyhow you please, except that decimal-two of a unit will have to be obtained by studying "elementary geology," and decimal-three of a unit by passing in "elementary principles of mining." And then you are a full-blown E.M., and may bore holes in the ground, and put up ricketty machinery, which will presently fall down and kill somebody.

It is folly to expect that a young man just entering college or a technical school can properly draw up a list of the subjects to qualify him for his intended profession. Yet, at the the Michigan Mining School he is required to do so before he enters, nor can he subsequently depart from his initially-chosen path of study without a great deal of fussy correspondence with the governors and staff. In one case out of every hundred a student, older and more experienced in worldly affairs than the rest, might be able to map out a line of work for himself; but the majority would certainly be ignorant both of the duties of their intended calling and of how they ought to prepare to discharge them properly. It is true that at this extraordinary institution a pupil may, if he likes, seek aid in drawing up his course of studies; but the error lies in giving him any choice in the matter. We do not wish to seem to imply that a student is at no time during his studies to select one or the other of two or more possible courses. In our opinion, it is necessary for every technical student to make such a choice, but not at the outset; not, in fact, until he has covered the essential groundwork of his profession. The first two years' work of a three years' course ought to be absolutely rigid; the student should have no power to alter it; its syllabus should be defined by competent teachers alone. The later and specialising studies will, of course, naturally be selected by the student himself.

It will be useful to inquire still further what it is that may reasonably be expected of a student before he shall be entitled to one of these modern business degrees. It may be assumed that the purpose of such a degree, whether in Medicine, Mining or Engineering, or any other business, is ostensibly to indicate that the graduate is competent to practise. Beyond doubt, the real value of a degree of this kind will be directly proportional to the truth with which it indicates the graduate's practical capabilities. However high sounding it may be, and however respectable the institution from which it may have emanated, the degree will sink speedily into discredit and become an object of scorn, if its only basis be a vellum certificate bolstered up by a pile of college note-books and a three-years' course of lectures. The recognition of this by the Faculty of Medicine has led to the invaluable requisition that the intending graduate shall gain a certain number of years' actual practical experience before he can qualify for the M.D. degree; and it would be well if a like restriction were imposed upon engineers wherever university or college engineering degrees are granted. The undergraduate in engineering should be called upon to leave his Alma Mater and go forth into the rough and tumble of actual practice; nor should he be permitted to return and graduate, until he can show by some years of experience that he is worthy of the name with which the degree would label him.

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(Continued from page 446.)

49. Clark's Fall of Potential Test (*continued*).—Mr. Herbert Taylor (of Messrs. Clark, Forde and Taylor) has devised the following method by which, without alteration to the usual ship and shore connections during submersion, the fall of

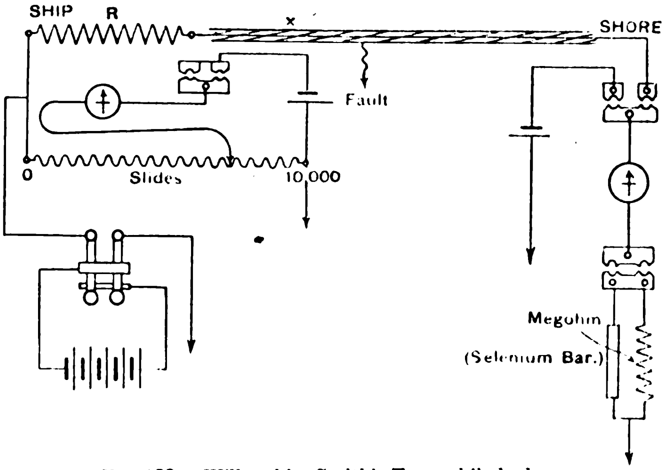

FIG. 152.—Willoughby Smith's Test, while laying.

potential test can be immediately applied in the event of a fault appearing in the submerged portion. The usual ship and shore connections are on Willoughby Smith's system, the apparatus, so far as affects the present test, being arranged as shown in Fig. 152. The slides are connected as in the bridge test, the current from the testing battery dividing between the fixed resistance R and cable on one side and the slides on the other. The galvanometer is connected as shown with one contact movable on the slides. The zero end of the slides is connected to the testing battery end, so that when balance is obtained the insulation resistance of the submerged portion is indicated continuously and is equal to

$$R\left(\frac{10{,}000}{s} - 1\right) \text{ ohms,}$$

where s is the slide reading. The ratio $\frac{10{,}000}{s}$ can be found at once by a table of reciprocals—that is by finding the reciprocal of s and moving the decimal point four places to the right.

Mr. Taylor adds a standard cell to each end and a megohm to the end on shore, with suitable commutators to plug them in as required (Fig. 153), without in any way altering the Willoughby Smith connections. Should a fault occur in the

* Copyright. All rights reserved.

Digitized by Google

submerged portion, ship's balance on the slides is at once thrown out and shore's galvanometer deflection falls, so that both ends are immediately aware of the fact. The potentials are distributed as in Fig. 154, the potentials P and p being measured on board and p_1 on shore. The ship then obtains a fresh balance, say of s divisions, equivalent to the potential

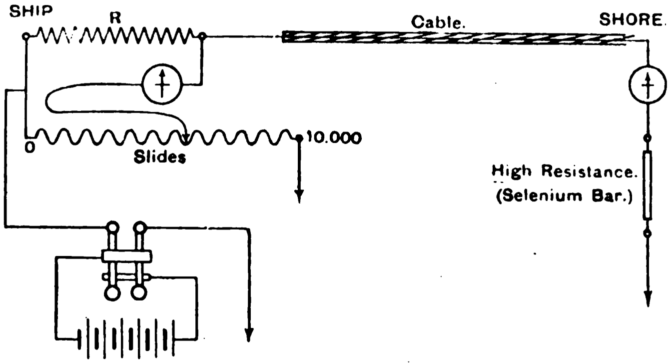

FIG. 153.—Herbert Taylor's Test for Localising Fault paid out while laying.

p, and then changes commutator plug over to connect the standard cell to slides. As the zero of the slides is at the battery end, the readings must be subtracted from 10,000. Say the reading with a standard cell of e volts is n divisions.

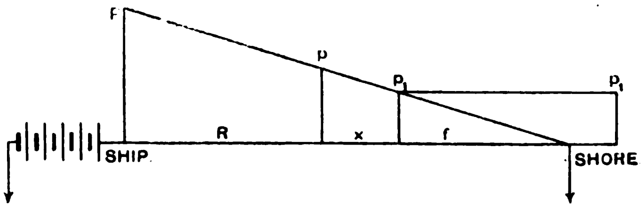

FIG. 154.

For convenience, let $10{,}000 - n = m$, then the potential per division is equal to

$$\frac{e}{m} \text{ volts.}$$

and the potential p is equal to

$$(10{,}000 - s)\,\frac{e}{m} \text{ volts;}$$

also the potential P is equal to

$$10{,}000 \times \frac{e}{m} \text{ volts.}$$

The values so determined are then used in the formula

$$x = \mathrm{R}\left(\frac{p - p_1}{\mathrm{P} - p}\right) \text{ ohms,}$$

where x is the cable resistance to the fault. Or the above values may be first substituted in the formula, which then becomes in its complete form

$$x = \mathrm{R}\left(\frac{10{,}000}{s} - 1 - \frac{p_1 m}{e s}\right) \text{ ohms.}$$

The shore simultaneously determines the potential p_1 in volts by comparing the deflections through one megohm produced respectively by this potential and by the known E.M.F. of a standard cell. Shunts must, of course, be allowed for if used. It will be noticed that the expression comprising the first two terms within the brackets multiplied by R is identical with that given above as representing the whole resistance in circuit, which, when a fault is present, is the resistance from ship to earth through the fault. And, since the whole formula represents x, the distance in ohms to the fault, it follows that the remaining term

$$\frac{\mathrm{R} p_1 m}{e s} \text{ ohms}$$

represents the resistance of the fault.

In the latest form of slides (by Kelvin and Varley) the contact stops, instead of being side by side on one circle, as in the usual form, are arranged as in Fig. 155, which allows more room, and therefore better insulation, between them.

The illustration shows the numbering of the coils, which in this form of slides is arranged for reading from the right-hand pointer b, instead of, as usual, from the pointer a. The terminals A and B of this box are connected to the contact stops numbered 100 and 99 respectively. As the pointers stand in the illustration the reading is 600. The improvements in the construction of the slides and the various uses of this important piece of apparatus are admirably treated upon in a work by Mr. W. A. Price, entitled "A Treatise on the Measurement of Electrical Resistance."

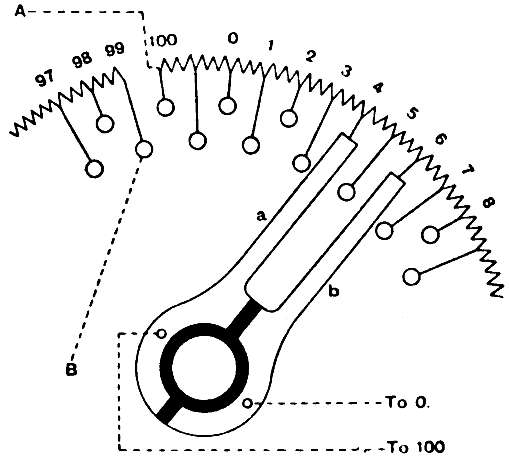

FIG. 155.—New form of Slides.

50. The Polar Test.—True as it is that improved protective covering on cables has led to a reduction in the number of faults with a corresponding increase in their resistance, rendering them difficult to localise, it is nevertheless the case that cables are as much as ever subject to fractures in shallow water. Ships' anchors are, in fact, the cause of more faults and breaks on the Atlantic cables than any causes at work in deep water. A comparatively large area of exposure is a general feature in such faults, and they are consequently much easier to deal with. Polarisation is small in amount and slow in action, and the ordinary bridge balance can be satisfactorily obtained, using

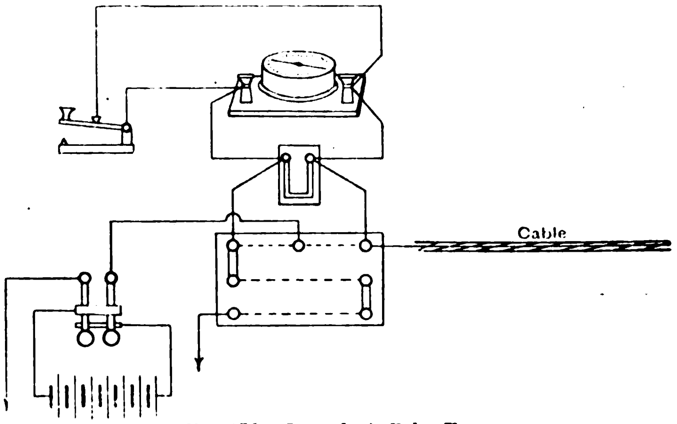

FIG. 156.—Lumsden's Polar Test.

both directions of current—that is, zinc continuously and copper for the short periods necessary. The negative or zinc current cleans the fault and lowers its resistance, while copper polarises it, or causes a deposit of salts (chloride of copper), which raises the resistance. Having balanced for copper, the spot moves off the scale in the opposite direction quicker or slower, according to whether the fault is of small or large area, and the rate of movement of the spot during the first second or two of polarisation is a guide to an experienced electrician what to allow for the fault.

On faults of this class the polar test, devised by Mr. Lumsden, is not infrequently adopted if time permits. The test is usually made with a horizontal galvanometer having

Digitized by Google

astatic pivoted needles, the connections being as in Fig. 156, and the distant end of cable being free (unless it is a fracture). The fault must first be thoroughly cleaned by a strong zinc current, using a battery as large as permitted by the rules. The time this should be kept on depends upon the behaviour of the fault. If it is noticed that the resistance no longer falls, but becomes steady, it shows the fault to be clean; but it may take several hours before this is observed. After the cleaning period, the fault is just sealed over by about one minute's application of copper current, and then the important part of the test begins. The zinc current is put on, causing a gradual fall in the resistance, and the plugs in the bridge are adjusted quickly to keep pace with the fall. This diminution of resistance arises from decomposition of the salts at the fault, and immediately a passage is opened through the coating, hydrogen is set free, the resistance is increased, and the needle moves rapidly away from its position of balance. At the moment before the evolution of gas occurs the resistance unplugged is that required, namely, the resistance up to fault plus the lowest resistance of fault obtainable. On repeating the test it is only necessary to apply the zinc current for a few minutes.

Other methods in use to which the reader is referred are Fabie's Test (Kempe's "Handbook of Electrical Testing"), and a method by Messrs. Harold W. Ansell and Julian E. Young in *The Electrician* March 15, 1889, entitled, "On the Localisation of a Partial Earth Fault in a Submarine Cable by the Fall of the Fault's Natural Potential."

(To be continued.)

ARMATURE REACTION.

In the course of the discussion which took place at the American Institute of Electrical Engineers on the Paper by Prof. H. E. Ryan and Mr. M. E. Thompson on "A Method for Preventing Armature Reaction" (see *The Electrician*, April 19, 1895, p. 765) Mr. E. A. Merrill suggested a method of graphically representing the nduction through a dynamo armature. Fig. 1 shows the relative

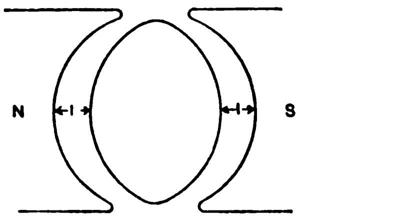

Fig. 1.

induction for every point at no load, the induction being uniform over a wide area and diminishing midway between the poles to zero, the distance I from the pole to the curve along the radial lines being proportional to the induction. If a strong current is passed through the armature the curve may assume the form shown in

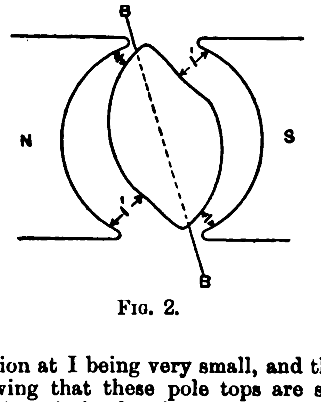

Fig. 2.

Fig. 2, the induction at I being very small, and the induction at I' very strong, showing that these pole tops are saturated. If, in addition, the position of the brushes and the line of commutation at B are indicated, the diagram graphically shows the strength of field where commutation takes place, and whether the voltage tends to be increased or diminished.

TECHNICAL RESEARCH.*

Every engineer is engaged in technical research, sometimes at his own expense, but oftener at the expense of his clients. The more important and commanding his position the greater is the proportion of his work that lies outside the boundary of assured knowledge. The ordinary everyday problems in construction are confided to the journeymen of the craft, who, out of the records of their experience, can generally find a fitting solution, or can even go one step in advance of what has been done before. But when not one, but many, stages have to be travelled into the unknown, there is needed something more than a general knowledge of the subject, and fair ability to reason by induction. Then it is that the real art of the engineer—an instinctive power in adapting the forces of nature to new ends—comes into play. If the matter be one dealing with machinery, it is generally possible to try small scale experiments in regard to a few, if not all, of the points of issue, and thus to eliminate some of the doubtful points in the subject. But there are many matters that are submitted to engineers the difficulty of which arises mainly from their magnitude, and which have to be treated entirely from a new standpoint. Only full-sized experiments would be of use, and therefore the whole affair becomes a gigantic piece of research work, for which the promoters find the funds, and on which the engineer stands to gain or lose reputation. Generally he gains it. It is perfectly wonderful with what a large measure of success new and difficult work is accomplished, and how exceedingly few are the serious failures. The mishaps that do occur are mostly connected with details that could be studied on a small scale if the engineer had time and money to investigate them. But while promoters will risk tens of thousands of pounds on a project, it is practically impossible to get them to provide a few thousands to be spent solely in acquiring knowledge on points that are apparently of subsidiary importance. They consider that technical research is no part of their business, and they decline to spend money in increasing the general stock of know ledge, although the first-fruits would be reaped by themselves.

Great advances in engineering practice wait more often upon details than upon principles. The conception of the compound marine engine is old enough, but it was not until a satisfactory surface condenser was produced that it became commercially possible. As long as the boiler was fed direct from the sea, 30lb. per square inch was the limit of practicable pressure, and compounding offered no advantage under this condition. The surface condenser, as now made, is a simple enough affair, yet it took many years to arrive at, because neither marine engineers nor shipowners were willing to spend the necessary money over a series of comparative experiments. Occasionally a sanguine individual ventured to try one, and when he found it unsatisfactory he generally preferred to face the known loss of abandoning it rather than enter into a series of experiments to perfect it. The triple-expansion marine engine furnishes another example. Up to about 1881 there was scarcely an engine of this kind constructed, and after that date there were very few built of any other kind. The deterrent cause in this case was a misgiving as to the possibility of finding a satisfactory material for boilers carrying 160lb. to 180lb. pressure, and complying with the requirements of marine service. Shipowners held back from making experiments for the benefit of the trade. For years they stuck to the compound engine, well knowing that a 20 per cent. economy was available, if only certain preliminary difficulties, by no means insuperable, could be overcome. But, naturally, no one was willing to pay for experience that would be immediately public property.

It is only under the protection of a patent that a manufacturer can afford to institute researches and pay the cost of experiments. It is a matter of common knowledge that some subjects which it would be advantageous to the public to have pursued are allowed to sleep because it is known to be impossible to secure a broad patent for any improvements that may be devised in connection with them. In years past attempts have been made to discover the best methods of bringing certain processes or materials into practical use, and, although success has not been attained, yet the way has been so far pointed out that it is hopeless to try and discover an entirely new means of attaining the end. The solution is a matter of degree rather than of principle, and as such does not lend itself to be secured under the provisions of the Patent Law. Superheating furnishes a case in point. It is generally believed that we are on the verge of a revival of superheating, and that it will be successful. But in years past there was a very determined attempt to use superheated steam. Apparatus was fitted in a large number of instances, particularly on board ship, and after extended trial was abandoned for several reasons. First and foremost, there was the difficulty of finding a lubricant that would not decompose under the influence of very hot steam. The introduction of mineral oils and vaseline has removed that source of failure without any effort on the part of mechanics. Then there

* From *Engineering*.

Digitized by Google

was the chance of the superheater becoming encrusted with salt carried over from the boiler with priming water. But salt in boilers is, or should be, a thing of the past, now that evaporators are so common, and thus a second source of failure has disappeared. The other difficulties were chiefly mechanical, and individually were not serious. But, taken in the aggregate, they are fairly formidable, and it is certain that they will take some time and a liberal expenditure of money to entirely overcome. As our columns have shown, attempts are now being made on a practical scale to introduce superheating. The attitude of the profession is one of expectancy; the majority are waiting to appropriate the result of other people's experiments, certain that nothing can be discovered that will furnish grounds for anything but a narrow patent.

It would be possible to adduce examples in many other departments of engineering to show that science languishes and progress is delayed because our predecessors advanced far enough to demonstrate the principles on which we should act, and yet fell short of attaining a commercial success. The last step, which they failed to take, often from not having the requisite material available, is capable of many solutions, and, therefore, seldom can be made the subject of a paying patent. A man may devise half-a-dozen means of attaining the end, and may fancy that he has closed every avenue to his competitors; but no sooner has he published his plans than alternative methods, of which he never dreamed, start forth like the ghosts at Macbeth's banquet. The man of business acumen waits and lets other people make his experiments for him, relying on his commercial ability to secure a fair share of the results, even if he be a little late in getting a start.

There is, however, one class of men who find it to their interest to make experiments without the hope of direct gain. We refer to professors in technical colleges. They are very favourably circumstanced for making researches, in that a large amount of apparatus is at their disposal, and that they have, to some extent at least, the command of funds for the purpose. Further, they generally have a considerable amount of leisure in the session, while the vacations are far in excess of what is necessary for physical and mental recuperation. They actually get more holiday than the school usher, who has not only to instruct his pupils, but who has also to undertake the formation of their characters and to join in their games. From morn till night, Sunday and weekday, the unfortunate assistant schoolmaster is boy-ridden. He eats with him, he walks with him, he plays with him, and often he sleeps with him. In spite of three intervals of rest per year, he grows narrow and petty, and his society is avoided by men of the world. But the professor is not subject to such contracting influences. He has his lectures to prepare and deliver, and then he is free. If he is to be something more than an animated text-book—a retailer of other men's ideas—he must experiment to furnish himself with original matter, or at any rate with novel illustrations. Further, if he have ambitions beyond the teaching of youths he must provide for a larger audience than that contained in his class-room. We once heard a civil servant say, "The way to make a reputation in the office is to make a reputation outside it," and that is true of others than those that work for the Crown. The engineering professor, until he has made himself a name by original work, is like a figure set up in a fair for every clown, who has learned to chip and file, to have his fling at. He is a mark for the cheap gibe of the man who has never attempted enough to find the depths of his own ignorance. If he would meet the world with a smiling face, untouched by such petty annoyances, he must be sustained by the esteem of the profession. The only way to earn this is by practical work, either in the way of construction or of research. The former avenue is often closed, and even if it be open, it is difficult of entrance to a man who has a permanent engagement which cannot be set aside at will. But at research the professor is on his native heath, and the profession is deep in his debt for much valuable information that has been evolved by a great expenditure of time and thought. Possibly all of it is not immediately applicable in daily life, but that which cannot be used to-day will be available at some future time, as the scope of our knowledge increases. If the total amount of engineering data that has been evolved in scientific colleges and schools could be separated from that obtained from other sources, and presented to us in bulk, we should be amazed to find how great and wide-spreading it is.

The powers of the technical laboratory are, however, distinctly limited. Full-sized experiments are beyond its scope. If no other consideration intervenes, there is always expense to be considered. In spite of the constantly rising fees charged for tuition, educational establishments share in a marked degree in that "eternal want of pence" that troubles the greater part of humanity. The available funds have to be spread over the largest possible area, like boarding-school butter. Investigations on a really large scale can, therefore, not be attempted. There is very little chance of getting these done elsewhere in a systematic manner if, as we have already pointed out, the results cannot be secured to the experimenter under the patent laws. One notable exception, however, is found in this country to this rule. We refer to the researches undertaken by the Institution of Mechanical Engineers. On these there have been spent hundreds—possibly thousands—of pounds, and the results have been freely given to the world. The researches made by the Institution on riveting, on friction, on steam engine economy, and on alloys, are splendid monuments of the large-mindedness of the Council. We know that certain Continental societies have carried out similar inquiries, but not, we believe, with the same completeness. It is doubtful if any private person could obtain similar results, since, were his purse ever so deep, he would not be able to command the harmonious and zealous assistance of a number of men of equal ability to those serving on the research committees. He could not offer them such an honourable position as that of being the chosen representatives of a large and influential professional body. He would be obliged to content himself with the services of one man of the first rank, assisted by others of less eminence.

It is strange that such a splendid example should be almost solitary. There is ample scope for other societies to undertake work of this kind without incurring the reproach of being imitators, or of trenching on each other's territory. Next to the necessary work of holding meetings and publishing their *Transactions*, there is no purpose to which their funds could be applied so directly valuable to their members and so remunerative to the profession. It is not necessary that a scientific body should have great accumulated resources. It is prudent, of course, to have something in hand to tide over a few years of bad trade, but that is quite a different matter to accumulating a vast estate. Engineers are not usually men with a long tale of ancestors, whose memory bids their descendants repay the benefits they inherit by making an ample provision for posterity. On the contrary, they have usually made their own way in the world, and are but little indebted to their forefathers. It is contrary to their instincts to make elaborate provision for those that will come after. If the next generation cannot maintain an institution for themselves in average times, they are not likely to derive much benefit from one existing on endowments. If a father have but a moderate sum to bestow on his family, it is far better that he should spend it in setting them up in life with all the advantages of education, rather than he should leave them in comparative ignorance with a limited fortune which is less than a competence.

On all sides we hear the cry for technical education. But if it be good for the youth to have knowledge gathered up for him, and carefully tabulated and codified, surely it is also advantageous for the grown man to have the knotty points of science unravelled for him, so that he may lay out his clients' money with advantage. Economists tell us that cheapening of production increases demand, and this does not apply only to manufactured goods. Scores of pieces of engineering construction are left unattempted because it is known that the cost so often exceeds the estimate. The reason is that the engineer has not the necessary data to guide him, and has largely to guess at his figures. The capitalist naturally declines to pay for the necessary research, since it is not his business to instruct the profession he employs; the private engineer has neither the time nor the money to undertake it; the professor finds the means at his command inadequate for the task. And so matters stand still, waiting till the investing public forget the smart of their last loss, and gather confidence for another plunge. In the meantime the average technical society reads Papers, distributes its sessional volumes, and congratulates its members on their wealth. It is a pity it does not do something to enable them to increase their individual incomes, by enabling them to furnish positive categorical assurances to their clients as to the efficiency of their designs and the reliability of their estimates.

It is easy, we know, to raise a host of objections to research work being undertaken by societies. It may be suggested that some departments of the profession will be aided and others will be neglected; that the council will consider the needs of their own practices and neglect those of the rank and file; that reputations will be created at the general expense and so on. It is so much easier and so much pleasanter to find objections than to undertake the work. But the fact remains that the Institution of Mechanical Engineers has now pursued its experiments for years, on a very extensive and liberal scale, and that no complaints have been made. A large amount of most valuable information has been gained, and there is the prospect that more will be added. But, we ask, why should it be left to one society to furnish funds and time and labour for the entire profession? The possibility and success of these researches have been demonstrated, and it is time that other bodies undertook them as well.

Crystal Palace Old Students' Society.—An association of old students of the Crystal Palace Engineering School, with the above name, has recently been formed.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July 27, 1895.*

Electric Railway Depreciation.—An officer of the principal electric street railway company of Brooklyn, while recently giving testimony in proceedings instituted to reduce the tax assessment of his company, stated that since January, 1892, its electric railway plant had depreciated to the extent of $5,000,000. This depreciation was explained to be due partly to natural wear and tear, partly to the rapid superannuation of electrical machinery necessitating the purchase of new types, and partly to the fact that a power house costing $700,000 had been abandoned on account of unfavourable location. In answer to a question as to the usual percentage of depreciation of electric street railway plants, he stated it to be from 60 to 70 per cent. While this testimony was *ex parte*, a reduction of taxation being the end in view, yet the exaggeration is not so startling as might be thought. Though few electric railways were installed previous to 1890, very many of our present roads are already suffering from serious depreciation, both of the track and of car and power house equipments. It has been found that the track suffers apparently out of all proportion to the increased speed of electric over horse cars, and many of the latest roads have adopted steam railway track construction. In the power house the wear and tear on the boilers and engines has also been very great, and the earlier roads have besides found it necessary to go to the expense of installing new types of engines and generators. The result of this is that the large returns so confidently expected through the substitution of electric for horse traction, and which in the first years were realised, are found to be illusory, and street railway investors are commencing to pass through the same process of disenchantment to which central station stockholders have in the past been subjected.

The Two-Carbon Arc Lamp Patent.—Judge Showalter, of Chicago, a few days ago rendered a decision denying the broad claims of the Brush patent on two-carbon arc lamps; but as the patent in question will expire in September of next year, the decision lacks the great force it would have had even a few years ago. It recalls, however, the singular monopoly the two-carbon lamp has had in this country, and which resulted in huge returns to the Brush Company, which collected $5.00 from every such lamp made by other manufacturers. Being the earliest arc lighting concern in the field, this Company set the fashion, and the public in time came to believe that all night lighting with single-carbon lamps would be an absurdity to attempt. Though a number of attempts were made to introduce the single-carbon lamp, at the present day its use in this country is practically unknown, and even with the fear of litigation gone, it will doubtless take some time to overcome the prejudice in favour of the double lamp for street lighting.

Electrical Method of Determining the Velocity of Projectiles.—Prof. A. C. Crehore has recently been conducting some interesting experiments at Fortress Monroe on the measurement of the velocity of projectiles, in which the principle of the magnetic rotation of the plane of polarisation of light is employed. The method consists in connecting the usual electrical gun screen in circuit with a closed coil, within which is a tube containing carbon bisulphide. As the screen is shot out of circuit, the intensity of the current is changed, with a corresponding change in the magnetic strength of the field of the coil, and a consequent change of the plane of polarisation of light passing through the tube. The apparatus is so arranged that when the circuit is broken a ray of light passing through the tube is extinguished by polarisation, by means of which a photographic record is enabled to be secured much more correctly than by the employment of a mechanically moved camera shutter.

NEW YORK, *August 3, 1895.*

Polyphase Electric Railway System.—It is rumoured that one of the large electrical manufacturing companies will before long put on the market a polyphase electric railway system. Polyphase-current street railway traction is a subject to which little or no attention has been given in this country by the general electrical engineering profession, doubtless for the reason that the action of induction motors has been much mystified by a treatment which has been almost exclusively mathematical. Engineers, therefore, were somewhat surprised some months ago when Dr. Bell asserted that such motors were entirely adapted for street railway use, and more recently Steinmetz, in an Institute discussion, went even further, saying that polyphase motors were much superior to continuous-current motors for electric traction.

Public Franchises.—Before the advent of the present reform government in Brooklyn the majority of the Council of that city, which became known as the "Cold Thirteen," carried on a very profitable traffic in street railway franchises. Among the franchises which they disposed of to their own personal gain was one to a clique of professional politicians, who received it gratis, though an existing street railway company had offered the sum of $250,000 in payment for the privileges which it conferred. The Flynn Grant, as it is known, was quickly disposed of to capitalists, who, after expending about $3,000,000, were thrown into consternation by a decision from a Court declaring the franchise void on account of the improper means by which it had been secured. After a lapse of some months, during which all work was stopped, another Court has just reversed this decision, and work is again proceeding. The loss of money through the stoppage of work would have been much more than sufficient to have, by honest means, secured the franchise by purchase from the city, and we cite the case as an example of many others in which it has been found that corrupt means of securing public privileges do not pay.

CORRESPONDENCE.

MAGNETIC UNITS AND NOMENCLATURE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Engineers will look with dismay at the six columns of new electrical units proposed by the Electrical Standards Committee of the British Association, and printed in your current number. One of the new units proposed is the "weber." Practical men are accustomed to use the C.G.S. or absolute unit of magnetic quantity, and have found it quite sufficient for their wants. This unit has, however, had a variety of names. It is often called a "line" or "magnetic line." Swinburne called it a "scot," and Evershed a "gauss." Other writers have used the terms "thom" and "hop," presumably abbreviations of the names of two distinguished electricians. I generally use the term "mag," which is short for "magnetic unit."

If the British Association would adopt a short and simple name for this unit, instead of new complications in the way of nomenclature, they would, I am sure, earn the gratitude of electricians, both practical and scholastic.

It has always appeared to me to be a doubtful compliment to take the name of a distinguished engineer or scientist, spell it with a small initial letter, as "watt" or "weber," and, in addition, may be, mutilate it like "farad," and use it to denote a perhaps extremely insignificant quantity. It is well known that one distinguished living electrician has declined the honour of having a unit named after him; and I venture to ask if Prof. Lodge would consider it a compliment to find mathematicians using the "lodge" as a unit of permeance or some equally abstruse quantity?—Yours, &c.,

London, August 2, 1895. J. A. KINGDON.

BELFAST GAS ENGINE ELECTRIC SUPPLY STATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read with much interest your description of the above station appearing in *The Electrician* for July 26th. It was, however, disappointing to myself and probably others to find that no official test of the gas engines taken at Belfast

Digitized by Google

is given in your article; although we are given to understand that a six-hours trial was carried out at the contractor's works, and it was found that the consumption of Kilmarnock gas did not exceed 24 cubic feet per electrical horse-power-hour. This has, however, nothing to do with the conditions of the contract, as it was most distinctly put that the engines must undergo a six-hours test running continuously at full power, and that the consumption of Belfast gas per electrical horse-power at the terminals of the machines must be less than 26 cubic feet per hour.

To take Kilmarnock gas as the test is unfair to the other firms who tendered for this work, as Kilmarnock gas, according to the "Gas Engineers' Annual," is of 28 c.p., and that of Belfast 17½ c.p., which would make the consumption of the engines at Belfast nearer 28 than 26 cubic feet per electrical horse-power per hour.

It would also be interesting to know how much cooling water is consumed when the engines are working at full power, as the provision for running the water directly through the cylinder jackets, and the use of a circulating pump, in addition to the ordinary cooling tank, point to a rather large consumption of water, and consequently increased expenditure in the working of the engines.

It would be most interesting to know something more about the points I have raised, as it is on these that the success or otherwise of electric supply stations driven by gas engines greatly depends.—Yours, &c., J. Robson.

August 2, 1895.

STANDARD SCREW THREADS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Mr. Elphinstone, in a letter in your current issue, has brought forward a subject that certainly is of immense importance not only to manufacturers, but to *purchasers* of apparatus.

That not only no two makes of B. A. threads are alike, but that consecutive deliveries by the same maker differ considerably, has been and is a source of constant annoyance and loss, which is only lessened by rigorous examination and rejection. This should not be; and not only users, but the manufacturers themselves would welcome the construction of accurate standards for comparison, as at present each user as well as manufacturer has one of his own, which is supposed to be *absolutely true*.

Mr. Crompton has had the subject in hand for some years, as the majority of makers are aware, and it is his intention to bring the matter before the British Association at their forthcoming meeting. It is to be hoped, therefore, that he will, as Mr. Elphinstone suggests, receive the support not only of those who, like himself, are interested in high-class work, but also of the manufacturers themselves in the solution of what is at present an anything but satisfactory state of things.—Yours, &c., W. Clark Fisher.

August 13, 1895.

INDIRECT ELECTROLYSIS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your number of to-day you have a "Note" on what is called "indirect electrolysis." Is this anything more than the well-known fact that if a metal plate be interposed between the poles in any electrolyte its two sides are respectively + and –, metal being deposited at the latter and oxygen or its equivalent set free at the other?

It is probable that in the case of a carbon plate being immersed in the central compartment gold would only be deposited if the impressed E.M.F. were sufficient both to decompose the solution of salt and the gold cyanide; below this point, although the salt might be decomposed, the energy would be insufficient to decompose the gold cyanide, and no gold would be deposited. The fact observed by Mr. Andreoli is taken advantage of in a well-known copper refining process, and also in Prof. Crookes' gold amalgamating process by reversing currents, every minute particle of gold between the two poles being alternately cleaned at the + side, and amalgamated by deposition of mercury on the – side.—Yours, &c., W. Stepney Rawson.

August 9th.

LEGAL INTELLIGENCE.

Consolidated Telephone Construction and Maintenance Company (Limited).

In the Chancery Division on Saturday last an application was made to Mr. Justice Chitty to sanction an alteration in the Memorandum of Association of this Company, which was incorporated in 1881 with a nominal capital of £300,000, in £1 shares, but owing to various alterations, the present nominal capital was £234,938, divided into 47,363 Six per Cent. Preference shares of £1 each, 224,850 Ordinary shares of 10s. each, and 75,150 Ordinary shares of £1 each. All the Ordinary 10s. shares had been issued as fully paid. There was now a prospect of profitable trading in matters which were not considered to be covered by the Memorandum of Association, and it was proposed to alter them so as to give the Company power "to manufacture, buy, sell and deal in articles, apparatus and inventions in connection with electricity or to which electric power may be applied, and to manufacture and deal in mechanical apparatus and inventions whether connected with electricity or not," and to alter the title of the Company to "The Consolidated Telephone Construction and Manufacturing Company (Limited)." The petition stated that owing to the expiration of patents belonging to the Company, and to the extensive importation of telephonic apparatus, the manufacture of telephones and apparatus connected therewith had become less lucrative than formerly, and the plant and appliances of the Company were only partially employed. The Company, therefore, proposed to engage in the manufacture of scientific and mechanical instruments, &c.

His Lordship sanctioned the proposal.

British Insulated Wire Company (Limited) v. Prescot Urban District Council.

In the Court of Appeal, before the Master of the Rolls and Lords Justices Kay and A. L. Smith, an appeal by the plaintiffs from the judgment of the Divisional Court (Mr. Baron Pollock and Mr. Justice Wright), on a special case stated in this action, was heard. Particulars of the action will be found in our issue of the 2nd inst., where it will be seen that, without calling upon defendants' counsel, the learned Judges gave their verdict in favour of the District Council, and declared the agreement entered into by the parties in November, 1892, as not binding, owing to the absence of a penalty clause.

During the course of the argument in the appeal, it was announced that defendants were willing to make the payments, but that the district auditor and the Local Government Board had refused to sanction such payments.

The MASTER of the ROLLS said that, this being the case, it was just and right that the arrears should be paid, and that the Local Government Board would doubtless allow this to be done. A new contract could then be entered into containing a penalty clause.

The case was adjourned to enable the parties to appear before the Local Government Board, and it was subsequently stated that the Board would sanction the payment of the arrears. It was further arranged that a new contract should be entered into in substitution for the present one, its terms to be settled, in case of disagreement, by some third party. Upon these terms the appeal was dismissed.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

SPECIAL NOTICE.—The 1895 (thirteenth) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. In addition to the old well-known features of the book, which are brought up to date, a quantity of new and useful matter has been added, rendering the book more than ever indispensable to the Electrical, Engineering, and Allied Trades. Price, 7s. 6d., post free 8s. 3d., abroad 9s.

The following New Books and Editions of "The Electrician" Series *can be obtained of the Booksellers or direct from the Publishing Offices:—*

Laboratory Notes and Forms.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett (*now ready*). Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"Electric Lamps and Electric Lighting," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

Digitized by Google

A Large-Sheet Table, giving full particulars of the Electricity Supply Stations throughout the Kingdom, can now be supplied mounted on stout board, with cord for hanging. Price: Varnished, 3s. 6d.; Unvarnished, 3s. —each post free. A Map showing positions of Supply Stations throughout the country is mounted on the back of the Table, and a Coloured Map of Metropolitan Electric Lighting Areas and a large sheet of Electricity Supply Statistics are also mounted on some copies, the price of which complete, post free, is 5s.

A Sheet Table showing Total Capital Outlay and Receipts and Expenditure for the year 1894 of the Statutory Electric Supply Undertakings of the Metropolis is now ready, printed on thick paper, price 6d. each.

A Sheet Table giving similar particulars in relation to Provincial Statutory Electric Supply Undertakings is now ready, printed on thick paper, price 6d. each.

"The Work of Hertz."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"Electric Motive Power."—A new work, by Mr. Albion T. Snell, with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"Electrical Engineering Formulæ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"Drum Armatures and Commutators."—By Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"The Incandescent Lamp and its Manufacture."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application

"Practical Notes for Electrical Students."—By Messrs. A. E. Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

"The Art of Electrolytic Separation of Metals."—A second issue of Dr. Gore's book is now ready, price 10s. 6d. post free.

"Electro-Chemistry."—This useful work, by Dr. G. Gore, is still on sale, the price being 2s., post free.

Tenders Invited.—Tenders are invited by the Vestry of Hammersmith, London, W., for complete schemes for public and private lighting, and for the supply of motor power in the compulsory area of the Vestry's Provisional Order. Particulars can be obtained of Mr. H. Mair, Surveyor to the Vestry. Tenders have to be sent in by 6:30 p.m. of Wednesday, Sept. 4th.

——— The Vestry of St. Mary, Islington, London, N., invite tenders for the wiring of the Vestry Hall and municipal offices. Particulars can be obtained from the electrical engineer to the Vestry (Mr. Albert Gay), 50, Eden-grove, Holloway, N., to whom tenders must be sent by 12 noon on Tuesday, 27th instant.

——— The Commissioners for the Control of Lunatic Asylums, Dublin, invite tenders for wiring the Killarney District Lunatic Asylum for the electric light. Plans and specification may be seen at the Asylum or at the Office of the Engineer, Mr. W. Leake, 30, Victoria-buildings, Manchester, and tenders, addressed to the Secretary, Board of Control, Custom House, Dublin, must be in by 10 a.m. on the 30th instant.

——— The Electric Lighting Committee of the Wakefield Corporation invite tenders for the supply and erection of (*a*) boiler and fittings, mechanical stokers and engine, economiser, feed pump, injector, &c.; (*b*) steam alternators, condensers, oil filter, fittings, &c., steam, exhaust, feed, blow-off and sundry pipes, valves and water tank, &c.; (*c*) main switchboard and instruments; (*d*) cables, junction boxes, culverts, and trenching, &c.; (*e*) transformers and switchboard, &c.; (*f*) arc lamps and posts; (*g*) meters, and (*h*) overhead crane. Tenders, addressed to the Town Clerk, must be in by 2 p.m. on August 24th.

——— The Portsmouth Town Council invite tenders for wiring the police stations at Buckland, Southsea, Portsmouth and Portsea, for the electric light. Tenders by the 27th inst. to the Town Clerk (Mr. A. Hellard), Town Hall, Portsmouth.

——— The Selby District Council require tenders for the erection of three lightning conductors for the water tower and chimney at their waterworks. Tenders to the Surveyor, Town Hall, Selby, Yorks, by the 19th inst.

——— The Municipal Authorities of Braila, Roumania, invite tenders for the concession for (*a*) lighting about 64 kilometres of public streets by both electricity and gas, and (*b*) 64 kilometres of public streets by electricity alone, and also for the concession for the construction and operation of a network of electric tramways in the principal thoroughfares. Tenders to the Maire, Hôtel de Ville, Braila, by October 2nd.

——— The Municipal Authorities of Strasburg invite tenders for an electric travelling crane. Tenders by the 24th inst.

Tenders Accepted.—The Walsall Town Council have accepted the tender of the Walsall Electrical Company for wiring, supplying and fixing 82 incandescent lamps at the Town Hall, for £139. The tender of Messrs. Fallowes and Wheatcroft, for wiring and fitting up the police station for the electric light, has also been accepted.

Tender Accepted.—The Bradford Town Council have accepted the tender of Mr. G. A. Steinthal, of Bradford, for the supply of two switchboards for their electricity works, for the sum of £185.

Tenders Received.—Eight tenders in all were received by the Ministre des Chemins de Fer, Postes et des Télégraphes for the supply and erection of plant for the electric lighting of the Schaerbeck-Nord railway station. The lowest was that of MM. Mulmann and Forkel, of Brussels (£2,012), the highest being £4,564.

Appointments.—The Stafford Town Council have appointed Mr. J. S. Highfield, of Clifton, Manchester, electrical engineer at their supply station. The salary is only £120 per annum. Mr. T. D. Clothier, of London, has been appointed electrician at a salary of £80 per annum.

——— The Bradford Town Council on Tuesday last adopted the report of the Gas and Electricity Committee recommending that Mr. A. H. Gibbings, electrical engineer to the Hull Corporation, be appointed electrical engineer at their electricity works at a salary commencing at £300 per annum, and that the salary of Mr. Dalton, assistant engineer to the same department, be advanced from £150 to £180 per annum.

——— Lieut.-Col. Petroff, Director of the Russian Police Department, has been appointed Director-General of Posts and Telegraphs in place of Gen. Besack.

——— The Islington Vestry (London, N.), have appointed Mr. C. H. Yeaman assistant electrician at their electricity works, Eden-grove, Holloway.

——— The Tunbridge Wells Town Council have appointed Mr. E. J. Stuart-Menteath assistant engineer at their electricity works.

Appointments Vacant.—The Governors of the Woolwich Polytechnic are willing to receive applications for the posts of lecturer in physics (salary £110 for a session of about eight months) and lecturer in mechanics (salary £70 for a session of about eight months). Some further particulars are given in our advertisement columns, and applications must be sent in by the 23rd inst.

——— The Governing Body of the Northampton Institute, Clerkenwell, E.C., are prepared to receive applications for the appointment of a principal. The salary attached to the office has been fixed at £600 per annum. Applications must be sent in by September 4th to Mr. J. J. Lambert, 8, Dowgate-hill, Cannon-street, London, E.C.

——— Messrs. Drake and Gorham invite applications for the post of head clerk in their goods department, with a commencing salary of £140 per annum.

Removal.—Owing to pressure of business Messrs. Russell and Lennard have removed from 22, Charing Cross, to more commodious premises at 135, Victoria-street, Westminster, S.W.

——— Messrs. Conze and Simon, "wholesale purveyors to the electrical trade," have removed their offices from 37, Queen Victoria-street, to 52, Queen Victoria-street, London, E.C.

Dissolution of Partnership.—Messrs. Roberts, Adlard and Co., who have hitherto carried on business as makers of slate switchboards, &c., at 47, Eastcheap, E.C., and 26, Bermondsey-wall, S.E., have dissolved partnership.

Partnerships.—Mr. G. L. Addenbrooke informs us that he has taken Mr. Ernest Scott into partnership. Mr. Scott served his time with Messrs. John Fowler and Co. (Leeds), and was afterwards with Messrs. W. T. Goolden and Co. and the Brush Company, while for the last year he has been chief of the drawing office department at the Electric Construction Company's works, Wolverhampton. Messrs. Addenbrooke and Scott request that letters to the firm be addressed to 21, Lichfield-street, Wolverhampton. Mr. Addenbrooke will, as hitherto, be frequently in London.

——— Mr. William Heath Merriman, A.I.E.E., has joined the firm of Slade, Templeton and Co., telegraph and electrical engineers and contractors, and the firm intend shortly to greatly enlarge and extend their business.

Liquidation.—It was resolved on July 4th that the Electric Trust (Limited) be wound up voluntarily. This resolution was confirmed on July 29th, and Mr. F. Cross, of 9, Bridge-street, Westminster, S.W., was appointed liquidator.

Iron and Steel Institute.—The annual meeting of this Institute is to be held in Birmingham next week, under the presidency of Sir David Dale, Bart. Arrangements have been made for visits to be paid to (amongst many others) the works of the Electric Construction Company, Thomas Parker, Tangyes', Elkington's, Osler's, and the station of the Birmingham Electric Supply Company. A number of interesting Papers will be read on subjects of interest to the iron and steel industries, including a Paper on "The Production of Iron by a New Process," by Mr. R. A. Hadfield; on "The Thermo-Chemistry of the Bessemer Process," by Prof.

Digitized by Google

W. N. Hartley; on "Tests of Cast Iron," by Mr. W. J. Keep (Detroit, U.S.A.), and Mr. T. D. West (Sharpsville, U.S.A.); on "The Estimation of Oxide of Iron in Steel," by Mr. A. E. Tucker; and on "The Use of Nickel in the Metallurgy of Iron," by Mr. H. A. Wiggin.

AGENCY.—Messrs. Hodges and Todd, electrical instrument makers, &c., of 30, Hampstead-road, London, N.W., have appointed Messrs. Wm. McGeoch and Co., Argyle-street, Glasgow, their sole agents in Scotland. A stock will be kept in Glasgow of Messrs. Hodges and Todd's well-known specialities.

THE LESSING DRY BATTERY. — Messrs. Krupka and Jacoby, of Queen-street, London, E.C., are now supplying an improved form of Dr. Lessing's dry battery. The new form is shown by the accompanying illustration. The battery is having a large sale.

ELECTRIC CLOCKS.—Mr. F. Hope-Jones notifies us that after some years of study and experimental work by himself and Mr. G. B. Bowell, these gentlemen claim to have succeeded in "dispensing with the complicated mechanism of the ordinary clock," and at the same time have secured reliability and time-keeping qualities never before attempted. The Synchronome Company has been established to work this system, and has issued a price list, which can be obtained of the Company, whose offices are at Birkenhead. The Synchronome system consists of one pendulum, kept in motion by means of two wheels and an electromagnet, which derives its energy from a small dry cell, the object of the pendulum being to transmit electrical impulses at regular periods along a single wire to any number of clock-faces. Amongst the advantages claimed by the system is that the only attention necessary is that the batteries alone require attention.

ASYLUM LIGHTING.—The various buildings and departments of the new Newcastle City Lunatic Asylum at Gosforth are to be lighted throughout by electricity. Electric motive power is also to be adopted for driving the domestic machinery, ventilating vans, &c. The work is to be carried out by the Corlett Electrical Engineering Company.

BLANTYRE (GLASGOW).—A discussion arose at the last meeting of the District Council on the lighting question. A proposal to light the district by electricity was defeated by the casting vote of chairman, and it was finally decided to adopt gas lighting.

BUXTON.—A letter to the District Council from the Brush Provincial Company, notifying their intention to apply for a Provisional Electric Lighting Order for this district, has been referred to a committee.

COVENTRY.—At their meeting on Tuesday the Town Council, on the recommendation of the Electric Light Committee, decided to adopt the Brighton method of charging for electric current.

CROYDON.—The Town Council have decided to purchase some three acres of land in Factory-lane to serve as a site for an electric supply station.

DERBY.—At the last meeting of the Town Council the report of the Electric Lighting Committee was presented, recommending the Council to make application to the Local Government Board for sanction to borrow £3,490 for building an annexe to the electricity supply station, and £524 for completing extensions of the electric light mains already undertaken. From the statement of the borough accountant, recently presented, it appears that the total capital expenditure on the electric lighting works to date is £49,657. 14s., and the total ordinary expenses for a period of eight months, from August 1, 1894, to March 31st last, amounted to £4,257. 3s. 1d. This sum, however, includes interest and repayment of loan for a whole year. The receipts for the same period amounted to £4,127. 12s. 1d., or a net loss of £129. 11s. (after the said repayment of interest, &c.). If the figures for the complete year's working were to hand, it is estimated that, instead of a loss, a profit of about £170 would be shown. A long discussion ensued, and Mr. Hart proposed an amendment, that the Council decline to authorise further expenditure until the existing arrangement with their consulting engineers (Messrs. Bramwell and Harris) was terminated, and that the Committee be instructed to dispense with the services of Messrs. Bramwell and Harris as soon as the boilers and coal sheds were completed. He thought that would be a suitable time to take the management of the works into their own hands. This amendment was, however, lost, and the Committee's report adopted.

DUBLIN.—The new Bar Library at the Four Courts is to be lighted by electricity. It is also intended to put the Library in telephonic communication with the various Courts. A deputation of ratepayers residing in the neighbourhood of Earl-street recently waited upon the Corporation to urge upon them the advisability of allowing the tramway company to extend their electric tram system from Annesley Bridge to North Earl-street and Nelson's Pillar. Mr. Nagle, who introduced the deputation, strongly supported the petition, and pointed out the inhabitants and frontagers along the line were unanimously in favour of the extension. The Lord Mayor, in reply, said that the Corporation were not in the slightest degree opposed to the introduction of the electric tramway system, and he himself was much in favour of it, but it was their duty to see that proper conditions were imposed upon the owners.

DUNDALK.—At the last meeting of the Town Commissioners a discussion arose on the unsatisfactory condition of the street lighting. It seems that the gas company, under the terms of their contract, do not light the street lamps on certain nights when the moon is at the full. When the moon happens to be obscured the terms of the contract are strictly adhered to and the town is left in total darkness. It will be remembered that the Commissioners obtained an Electric Lighting Provisional Order in 1885, and an unsuccessful attempt was made to introduce the electric light into the town. The Provisional Order expired in 1892, but a renewal was obtained, and the terms of the Order somewhat extended. The renewed Order will expire in about 12 months, and the Town Clerk has called a special meeting to discuss the electric lighting question.

ELECTRIC NOVELTIES.—A standard intended for night use has just been delivered from the Kiel dockyard for use on the German Imperial yacht "Hohenzollern." The flag is four metres square, and the design is traced in coloured electric lamps. The device is stated to work very satisfactorily.

ELECTRIC TRACTION IN FRANCE.—Two new electric traction companies have recently been formed in France, one by the Banque de Paris et des Pays Bas and the Société d'Eclairage Electrique du Secteur de la Place Clichy. The capital of this Company, which is to exploit the Siemens electric traction system in France, is 2,500,000fr. The second is the creation of the Paris branch of the Société Anonyme Bouckaert of Brussels, who are the representatives of the Elektricitäts Aktiengesellschaft vorm. Schuckert and Co. The Société Anonyme des Tramways Mécaniques de Paris et des Environs (St. Germains to Poissy) has increased its capital to 300,000fr. The Raincy Montfermeil Electric Tramway (25 kilometres from Paris) was inaugurated on the 15th inst. The contract has been carried out by the Compagnie Française pour l'Exploitation des Procédés Thomson-Houston, which has also received an order to electrically equip the tramways of Enghien, Montmorency and St. Gratien, small towns to the north of Paris.

ELECTRIC TRACTION IN THE MIDLANDS.—It is proposed to construct an electric railway between Ashbourne and Derby. The line is to pass Mackworth, Kirk Langley and Brailsford, a distance of more than 13 miles. The estimated cost is expected not to exceed £62,300. The line would be worked on the overhead system, with a generating station near the Brailsford Brook, about 7½ miles from Derby.

ELECTRIC TRACTION IN RUSSIA.—A contract for the construction of a network of electric tramways in the town of Nijninovgorod has, it is stated, just been placed with the Maschinenfabrik Oerlikon.

GLOUCESTER.—The Great Western Electric Light and Power Company have notified the District Council of their intention to apply for a Provisional Order. The matter has been referred to the Finance Committee.

HAMPSTEAD.—The Library Commissioners have decided to light the Public Library by electricity. The contract for wiring and fitting up the building has been entrusted to Messrs. S. Newton and Co.

LINCOLN.—The Brush Provincial Company have notified the City Council of their intention to apply for a Provisional Electric Lighting Order for this city.

MIDDLESBOROUGH.—The Town Council, on the recommendation of the Electric Lighting Committee, have decided to engage the services of an electrical engineer (at a fee of £50) to prepare a report on the question of the introduction of the electric light into the town.

NEW SUBMARINE CABLE.—It is stated that the French Government has given a contract to the Société Industrielle des Telephones, Paris, for the supply and laying of a telegraph cable between Obok and Djibonti, the contract price being £13,600.

NEWPORT (MON.).—The Town Hall and clock are to be lighted electrically.

NOTTINGHAM.—The electric light continues to grow in favour in Nottingham. The Town Council have decided to extend the electric light mains along Friar-lane for the purpose supplying

Digitized by Google

current to the Castle Museum and to the Mechanics' Hall, where the billiard and reading rooms are to be lighted electrically. Some small extensions have also been made in the Theatre Royal quadrant, and the mains have been extended as far as University College along Goldsmith-street. The adoption of the electric light for the Masonic Hall is under consideration.

PRIVATE HOUSE LIGHTING.—The Tayler Smith Electric Company are carrying out an installation of the electric light at 6, Bowland-houses, London, W., for Admiral Sir Windham Hornby, K.C.B.——Messrs. Rashleigh Phipps and Co. are fitting Lord Dudley's new house in Carlton-gardens, London, for the electric light.

PORTSMOUTH.—It is stated that a scheme for the introduction of a system of electric traction on some of the existing tramway lines in Portsmouth is under consideration.

QUEENSTOWN.—At a special meeting of the Town Commissioners on Tuesday it was decided to prepare an advertisement inviting tenders to light this town by electricity.

SANITATION.—Engineers, in common with the rest of the public, are interested in all that affects the perfect sanitary condition of our homes and workshops. The Sanitas Company, who are well known as proprietors of a number of valuable sanitary preparations, have just issued a pamphlet entitled "How to Disinfect," which is a guide to practical disinfection under all circumstances, and which gives a large amount of very useful information and particulars how to use the Sanitas preparations The pamphlet can be obtained from the Sanitas Company, Three Colt-lane, Bethnal Green, London, E.

SOUTHBOROUGH.—The District Council have declined to give their consent to the application of the Guildford Electricity Supply Company for a Provisional Order for this district.

SOUTHPORT.—The principal streets are to be lighted by electricity for the first time to-day (Friday).

SPAIN.—An electric supply station is in course of construction at Hellin (Albacete). The plant is being put down by Messrs. Levi and Kocherthaler, of Madrid. A small station is also being erected at Herrera (Caceres). A station has just been completed and put in operation at Orense, Galicia. Plans have been prepared for the establishment of a supply station at Tarazona, a fortified town in Aragon. A contract has just been given to a Barcelona firm for the establishment of a supply station at Puigcerda.

THE ELECTRIC LIGHT AT WESTMINSTER ABBEY.—The organ loft at Westminster Abbey is to be experimentally lighted by electricity, and, if the light is approved, the Abbey will be fitted throughout for the electric light. The organ loft is at present lighted by gas. The success of the electric light at Westminster will probably induce the authorities of St. Paul's Cathedral to make another attempt to light that noble building effectively by electricity, a previous attempt having failed owing to the use of arc lights, which were found to be unsuitable for the interior of such a building.

THE EMPLOYMENT OF THE TELEPHONE BY THE CONSTABULARY.—The West Riding (Yorkshire) Joint Finance Committee have been considering two important schemes for installing a private service of telephones for the use of the West Riding Constabulary. The larger scheme provides for divisional headquarters at Wakefield, Barnsley, Rotherham, Doncaster, Pontefract, Goole, Sheffield, Tadcaster, Knaresborough, Otley, Leeds, Keighley, Bradford, Halifax, Saddleworth, Huddersfield, Dewsbury, and Todmorden, with sectional stations at Normanton, Penstone, Rawmarsh, Mexbro', Castleford, Hillsborough, Ripon, Harrogate, Ilkley, Bingley, Shipley, Pudsey, Cleckheaton, Brighouse, Elland, Holmfirth, Honley, Batley, Heckmondwike, Morley, Mirfield and Hebden Bridge. The smaller scheme only provides for the connection of the divisional headquarters. The cost of the larger scheme is estimated by Mr. W. E. L. Gaine, General Manager of the National Company, at £8,140, and the smaller scheme at £6,080, for labour only. The lowest annual charge which the National Company can make is £1,436, or £1,400 on a 15-years contract, in respect of the larger scheme, and £1,059, or say £1,000, on a like contract in respect of the smaller scheme. The sub-committee recommend the adoption of the larger scheme, subject to certain conditions, which it is suggested should include a clause that the wires and other connections shall be the property of the County Council at the expiration of the 15 years. The National Company agree to the County Council extending the system to other police buildings than the divisional head-quarters and the principal sectional stations named in the scheme. The Joint Committee have adopted the sub-committee's recommendation.

THE PACIFIC CABLE.—The very various Governments, firms, and persons who are about to lay or finance the Pacific cable have had a quiet time for quite a month past—probably enjoying seaside repose. According to Reuter's agency "it is stated here (Victoria, B. C.) that Mr. F. W. Mackay, the Canadian Pacific Railway, and a number of San Francisco capitalists are co-operating with a view to securing the contract for laying the projected Pacific cable." The name of the makers of the cable is not given this time.

THE PROPOSED JUNGFRAU ELECTRIC RAILWAY.—The preliminary surveys for the proposed railway up the Jungfrau will, it is anticipated, be completed as far as the Eiger station before the winter, and the construction of the section between Scheidegg and the Eiger glacier is to be commenced in the spring. Tenders are shortly to be invited for the laying of the permanent way, for the construction of the stations and other surface works, and for the supply of the necessary electrical appliances and rolling stock.

WALSALL.—The Town Hall and borough police station are being fitted for the electric light, and the Town Council have decided also to light the borough offices electrically, at an estimated cost of £62. 10s. The Council have decided to borrow money for extensions to their gas works, although Mr. Clare (a member) urged that the matter should be postponed for a year to enable them to properly judge of the progress made by the electric light.

WEYBRIDGE.—Electric lighting matters are in a somewhat confused state in this village. A public meeting was held last week which, however, arrived at no decision, but adjourned for another week. At the last meeting of the District Council a lengthy discussion arose on the subject, the members discussing a report from the sub-committee appointed to consider the subject, and a further report from Messrs. Spagnoletti and Crookes, who had been called in to give expert advice to the Council, but no decision was arrived at.

WIGAN.—The Local Government Board having sanctioned the borrowing by the Wigan County Council of the required sum for extensions to the gas works, the Chairman of the Gas and Electric Lighting Committee, at the last meeting of the Council, in reply to a question, said he was afraid the introduction of the electric light would have to be postponed for a time. He thought the Sub-committee appointed to consider the matter were making a mistake, and he wished them to be unanimous before any electric lighting proposal was placed before the Council for consideration. Mr. Fyans said that, although the Sub-committee could not agree, the ratepayers desired that the matter should be pushed forward. Owing to the injurious effects of gas the priceless treasures on the shelves of the Library were deteriorating steadily, and were they to understand that because one or two gentlemen on that Committee could not see the expediency of adopting the electric light that the Council in general were not permitted to express their opinion on the matter? He believed that the Council were almost unanimous in their support of it. Electric lighting would be of immense benefit to the local institutions, and if the question were delayed much longer they would only be giving other people the opportunity of doing what they had now the power to do themselves. Other equally strong opinions in favour of adopting an electric lighting scheme for the town were expressed by Ald. Phillips, Mr. Johnson and Mr. Laycock.

YORK.—At their last meeting the City Council once more considered the report of the Electric Light Sub-Committee, which recommended that the tender of the Electric Construction Company for supplying the necessary plant for the electric lighting of the city, and the working of the same for seven years, be accepted. The amount of the tender was £8,650. Mr. Ald. Agar moved the adoption of the report. After various opinions had been expressed as to the practicability of the proposed scheme, Mr. Scott, who favoured a continuous-current low-tension system, moved an amendment that Prof. Kennedy's opinion be obtained as to which system he considered best for the city. This was lost by 23 to 7. A motion for the adjournment of the discussion was then made and defeated, when a further amendment by Mr. Shaftoe, "That the matter be referred back to the Committee, with instructions to select an expert to advise them which system is the best, the Committee then to ask for tenders on the selected system, and to report fully to an early meeting of this Council," was adopted by 15 to 11.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

July 16, 1895.

13,618. S. F. BEEVOR. London. Improvements in or relating to electrically-actuated mechanism.

13,619. J. WETTER. London. Improvements in and connected with underground conductors for electric railways and tramways. (The Electrizitäts-Aktiengesellschaft vormals Schuckert and Co., Germany.)

13,635. H. G. GRIER, A. G. GRIER, and A. S. HOTTLE. London. Improvements in electric gas lighters.*

13,636. L. S. CRANDALL. London. Improvements in electric signalling apparatus.*

July 17, 1895.

13,663. J. PESCHEK. London. Improvements in connecting plugs and switches for electric lighting and power purposes.

13,670. H. COOPER. Manchester. Improvements in and connected with electrical incandescent lamps.

13,689. A. V. NEWTON. London. Improvements in the manufacture of incandescent electric lamps. (A. Nobel, France.)

13,702. H. PIEPER (FILS). London. Apparatus for regulating or measuring electric currents.*

July 18, 1895..

13,727. J. A. KINGDON. London. Improvements in or relating to combined alternators and dynamos and the like, and to the distribution of electricity thereby.

13,730. W. ROWBOTHAM and H. LEVETUS. London. Improvements in and relating to primary batteries.

13,760. C. RALEIGH. London. Improvements in and in connection with the working of electric tramways on the accumulator system.

July 20, 1895.

13,872. J. A. KINGDON. London. Improvements in or connected with steam alternators and the like, and in the mode of operating them for the distribution of electricity.

13,900. R. W. GORDON. London. Improvements in galvanic batteries, [Date applied for under Patents, &c., Act, 1883, Sec. 103. January 31, 1895, being date of application in United States.]*

July 22, 1895.

13,934. F. GRAY. London. Improvements in the method of generating electricity for lighting or motive power.

13,956. A. G. NEW. London. Improvements in trolley systems of electric propulsion and in apparatus therefor.

13,957. A. G. NEW. London. Improvements in trolley systems of electric propulsion and in apparatus therefor.

13,958. A. G. NEW. London. Improvements in trolley systems of electric propulsion and in apparatus therefor.

13,961. H. H. LAKE. London. Improved connector for the rails of electric tramways and railways. (The Compagnie de l'Industrie Electrique, Switzerland.)

July 23, 1895.

13,978. A. K. BONTA. Manchester. Improvements in the method of and means for stopping electrically-propelled cars.*

14,019. W. ACKROYD and W. BEST. London. Improvements in or connected with apparatus for electrically lighting miners' safety lamps.

14,021. E. SMITH. London. Improvements in and relating to phonographs and the like.

14,023. P. A. NEWTON. London. Improvements in writing telegraphs. (T. Ewing, jun., United States.)*

14,033. G. K. B. ELPHINSTONE, of the firm of Elliott Bros. London. Improvements in galvanometers. (H. Rowland, United States.)

14,049. D. HIGHAM. London. Improvements in electric arc lamps.*

14,051. B. PELL. London. A method and apparatus for electrically transmitting writings or drawings.

14,066. The Hon. C. A. PARSONS. London. Improvements in winding armatures for dynamos and electro-motors, specially applicable to alternators and alternate-current motors.

July 24, 1895.

14,114. J. HESSBERGER. London. Electrical apparatus having movements determined by variations of the electrical resistance of bismuth in a magnetic field.*

14,134. C. LANGDON-DAVIES. London. Improvements in rapid telegraphic transmission on cable lines.

July 25, 1895.

14,142. M. W. W. MACKIE. London. Improvements in apparatus for the recovery of gold by electrolysis from the sea.

14,147. R. C. SAYER. Bristol. Improvements in electric and other railways and in vehicles therefor.

14,158. W. ROWBOTHAM. Birmingham. Improvements in and relating to primary batteries.

14,160. E. W. LANCASTER. Birmingham. Improvements in conduits for electric wiring.

COMPANIES' MEETINGS.

Crompton and Co. (Limited).

The seventh annual general meeting of the members of this Company was held on the 9th inst. at the Cannon-street Hotel, under the presidency of Viscount Emlyn.

The SECRETARY (Mr. Francis R. Reeves) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, there is a foot-note to the accounts in the auditors' report, which is as follows: "We have examined the foregoing balance sheet, with the accounts and vouchers relating thereto, and certify it to be in our opinion correct, with our letter of this date." I will ask the Secretary to read that letter, so that the shareholders may know what it is.

The SECRETARY read the letter, which was dated the 31st ult., and was addressed to the Chairman and Directors of the Company. It was as follows:—"Gentlemen, we beg to report having audited the accounts of your Company for the year ended March 31st last. The stock and work in progress have been certified to us as before by the Works Manager, and the additions to capital by Mr. Crompton, one of the Managing Directors. The depreciations have been taken at the same rates as previous years. The reduction in the capital by the surrender of £20,000 Ordinary shares by the vendors, and sanctioned by the Court of Chancery on June 25th last, has been given effect to in the accounts, and the amount written off the value of investments. With regard to the trade debtors and remaining investments, we are informed that in the judgment of the Board, arrived at after careful examination, the amount to be set aside to reserve fund will be a sufficient provision to meet any loss."

The CHAIRMAN: I have now to propose the first resolution, and in doing so would say a few words as to the report and accounts. With reference to the unfortunate reduction of profits, as shown by the Directors' report: while this result is much to be regretted, there is a satisfactory feature in connection with the business not mentioned in the report, which is, that although there have been considerable reductions in prices during the period covered by the report, still, probably, the principal reason for the falling off of profits is attributable more to the falling off in orders during the earlier period of the year under review than to the reduction of prices, for it is a fact that during the first six months of the year business was so slack that practically no profit at all was made in that period. That means that our standing charges, of course, were high, and we could not get sufficient profit by the work we had to do. The whole of the £7,000 profit shown in the balance sheet was practically earned during the latter half of the year, when the order book was well filled and the works were kept extremely busy. This satisfactory state of affairs still continues, and several good contracts have recently been taken at higher prices, which justify the Directors in looking forward to better results in the current year. There is no doubt that a healthier tone prevails in business generally, and particularly in the electrical branch. During the year the Directors effected several changes in the working of the Company with a view to future economies, and one of the most important of these was the removal of the accountants' department of the Company from Chelmsford to London, and the enforcement of a stricter system of departmental work, whereby the Directors are able more accurately to gauge the results of the working of the different departments, and so to retain a better control over them. This change entailed for a time some considerable delay in the keeping of the accounts, but happily this is now all at an end, and the Directors will be able in the future to be supplied earlier and more accurately with particulars of the working of the departments than they have hitherto been. From an examination of the statement of accounts accompanying the report, the shareholders will see that the Court of Chancery has sanctioned the resolutions passed last year for the reduction of capital, and this order was obtained without the usual corresponding order to add the words "and Reduced" to the title of the Company. The Directors had hoped that the debentures issued in January last would have been fully subscribed, but in this they were disappointed. The amount, as will be seen from the report, actually taken up by the public and the shareholders was £32,850. With this the Directors were able to reduce the loans from the bankers, and a small amount of additional working capital was brought into the business. On the other side of the balance sheet it will be seen that the stock-in-trade has been slightly reduced from the previous year, while the trade debtors have increased some £7,000; at the same time the work in progress on contracts is nearly £4,000 less than in the previous year, and consequently by that much the trade debtors have been proportionately increased. The investments in the subsidiary and other companies have been, of course, reduced by the sum of £20,000 written off in accordance with last year's resolution, but although this amount is written off the investments remain for what they are worth in the coffers of the Company, and some of them might hereafter improve in value. In turning to the profit and loss account it will be seen that the reduction in gross profits brought forward is about £5,000, while on the other side the trading and office expenses have been reduced by £730. The repairs and depreciation have naturally increased with the larger amount of the Company's property in plant, tools, &c., but there is one item in connection with this account which should be mentioned, viz., that a sum of nearly £600 which in former years had been debited to capital account as an expenditure on plant and tools has this year been debited to repairs account in profit and loss, and by this amount, of course, the profits are apparently reduced. The item in question is for the purchase of small tools, which the Directors feel should more properly be charged to revenue, since the amount of depreciation annually written off the plant and tools account, while more than sufficient to meet the proper depreciation on large tools, is practically not sufficient to provide for depreciation and loss on small tools, and they have thought it better, therefore, to charge the amount to profit and loss rather than to capital. There is one other item which may be mentioned as explaining somewhat the reduction of profits, and that is, that a loss was made on one of the contracts carried out during the year, a loss entirely arising through the misreading of a specification, from which it appeared afterwards it was intended to provide for more work than the manager of the department entrusted with the work had estimated for. The engineer for the contracting company insisted upon his reading of the specification, and the Company had to submit and carry out the work. These two items account for a substantial proportion of the deficiency in profit and loss account. In the previous year's report a statement was made that the Directors considered the cooking and heating department would be likely to prove a valuable addition to the Company's business, and this anticipation seems likely to be fulfilled, inasmuch as since the closing of the accounts the Directors have granted a licence to a firm in France to manufacture and sell the cooking appliances under which the licensees have to pay a substantial royalty on every article made and sold, and in addition—what is rather unusual in such cases—the Company has received the sum of £1,000 for granting the licence. The licensees have the option of purchasing the patents for France within two years for a substantial sum, and it is very likely that they will take advantage of this option. The Directors have also during the last week concluded arrangements for licences for Switzerland and Austria-Hungary, and in the latter case the licensees have the right of acquiring the patents within a fixed period. With a view to concentration and economy, the Directors have decided to close the works at Lillie-road, which were taken some years ago in consequence of the large London contracts, and in a short time the whole of the work now done at Lillie-road will be carried on at Chelmsford. There is no doubt this will effect a considerable saving, and the Directors hope either to let or sell the lease of the Lillie-road works. In my remarks last year mention was made of the satisfactory amount of the orders received from Sydney for the Australian Company, it having been apparent at that date that the Australian business would be likely to show a considerable improvement during the year: unfortunately, however, it subsequently transpired that the contracts which the manager of the Australian Company had made were of a most unsatisfactory character, in that they entailed upon the Company receiving payment by instalments deferred over several years, and in consequence the Australian Company very soon found itself in difficulties, and the debenture holders decided to take steps for the appointment of a Receiver. This Company being the largest creditor and debenture holder, the Directors were able to secure the appointment of the Secretary as Receiver, so that the work of realising the assets will be carried out under their immediate supervision. As to the shares held by this Company in the Australian Company, these were written off in the depreciation of assets last year, consequently the Company have only debentures and the balance of the trading account, for which they also hold debentures as security. It is hoped, although the realisation may take some considerable time, that the result will prove so far satisfactory that the debenture holders and secured creditors will be paid in full. There is undoubtedly a considerable amount of business to be done in Australia, and since the stoppage of the Australian Company, offers of contracts at good prices, and for cash payments, have been received by this Company, and in consequence it has been thought advisable that Mr. Albright, one of the Managing Directors, should proceed to Sydney with a view to investigating these contracts and making arrangements, if the result of his investigation should be satisfactory, for a continuance of the Company's business there. Mr. Albright sails to-morrow, and advantage will be taken of his presence in the Colony to assist in the realisation of the Australian Company's assets at the same time. Reference was made last year to the arc lamp department, which was then reported to be doing well; it is satisfactory to be able to state that this department continues to show very excellent results, and the lamps are sold practically as fast as they can be made. When the Company was first formed arrangements were made, as was natural and proper, that the two partners in the firm of R. E. Crompton and Co. should consent to give their services to this Company for a period of years as Managing Directors. This period having now expired, the Directors have made arrangements whereby the Company will continue to have the benefit of the services of Mr. Crompton and Mr. Albright, who, besides being by far the largest shareholders in the Company, Preferred and Ordinary, have had the building up of the Company's business, and presumably, therefore, should be the best able to continue its management. The Directors, while regretting that the last two years' reports should have been unsatisfactory reading, have reason to believe that the period of depression in the Company's business is passing away, and that the future promises considerable and satisfactory improvement, resulting, it is to be hoped, in better reports and a return to a dividend-paying position. I wish I had a better report to give you as far as the question of dividend is concerned, but I think there are a good many cheering signs in the future. We are full of work now. We are economising in all departments as far as we possibly can, and I hope that the next report of the Directors may be one of a satisfactory character. I have endeavoured to tell you the whole story, and you know all the facts that I could put before you. I now move—

"That the report and audited statement of accounts for the year ended March 31, 1895, be and the same are hereby received and adopted."

Mr. R. E. B. CROMPTON: I beg to second the Chairman's motion, and I do not propose to add many words. I will not prophesy as to the future for I think we have had enough of prophesying. We will do our level best to pull the thing round, and I think that that process commenced about six months ago, and that, as your Chairman has said, things are much more hopeful now. I can only assure you that, as far as the Managing

Digitized by Google

Directors are concerned, they will do their utmost to improve the position of the Company, and I need hardly say that there is no shareholder among you who suffers so much as I do from the present state of affairs.

Mr. EVANS asked various questions respecting certain items in the accounts, and maintained that some of the assets ought to be written down—such as the goodwill and the patents, and in this was supported by Mr. KITCHIN, who urged that they must face the position which was shown by their assets, and if the Directors were not prepared to face it he urged the shareholders to appoint a committee of investigation, and see what the assets were worth.

Col. WOOD expressed a desire to hear more about the contract which had been entered into and which had not paid.

Mr. CROMPTON said it was a very small affair. In spite of all Mr. Kitchin had said it was very difficult for any firm to get profitable contracts unless they took financial risks; in all ordinary cases the profit was very small indeed. In the particular contract in question the wording in the specification was fairly clear, but a mistake was made, which wiped off just the possible profit that would have been made on the job.

The CHAIRMAN: I am glad to answer the other observations which have been made. In reference to Mr. Evans's remarks, I do not know in what way it is suggested that we could give further details. It is true that we might do so, but I do not know that it would be any advantage to the shareholders. With regard to the goodwill, I think it is placed at a fair figure, and it is justified. Our business has very largely increased since that figure began at £30,000. I am certainly not prepared to say that it should be written down by sixpence. As to the suspense account, Mr. Evans says that we ought to write off a part of it. We write off £1,000 this year, as mentioned in the report, from the £9,777. With regard to the patents, a remark was made that it was monstrous that we wrote nothing off them—but we write 10 per cent. off them. The amount against the item of patents is always increasing, but we write off from the total sum 10 per cent. I was asked why we had not got the £1,000 to which I referred from the French contract we have just made. The reason that sum is not in this year's account is that it does not belong to the present account, but it will come into the accounts next year. Then we are asked whether we are satisfied as to the doubtful debts account. That account stands at £277, but, as mentioned in the report, we are adding a further sum of £1,000 to it. Our experience in past years has shown that that is sufficient. The Chelmsford Electric Lighting Company is now beginning to pay its way, and is doing very good work. It has been of enormous value to the Company as a training ground for the staff, and we believe it has now become a paying concern, and that we are fully justified in keeping it at this figure. With respect to one other point, we have been told that the more business we do the worse our position is, but if Mr. Kitchin had arrived at the meeting earlier he would have heard me state that the reason for our loss this year was that in the first half of it we had not sufficient work to do, while our standing charges remained the same. Since then we have had a large amount of work, with the result that we are going on better. I believe that if a very large business came to us we should do very well. I do not think it is of any use my going into the question about Crompton and Co. being one of the worst of the "cutting" firms. I will merely say that I think any one concerned in this particular work would find it impossible to get any business unless he tendered at a very low price. If we had not had the business which we had in the last six months we should be in a far worse position now than we are.

After a few further questions had been put and answered, the motion for the adoption of the report was carried.

Resolutions were afterwards passed re-electing the retiring Director, Mr. Bernard Gibson, and the auditors, Messrs. J. H. Duncan and Co.

The CHAIRMAN then intimated that in the course of the last five weeks he had been appointed to the Chairmanship of the Great Western Railway Company, an office which he had held for just a month. He need hardly state that the duties of that position were not a sinecure, and he found, in fact, that the pressure of work in connection with it was so great that he did not think he could undertake any other business. The result, he feared, was that that would be the last time that he could be among them. It would not be fair for him to remain unless he could attend to the work, and he really found that all his time was now taken up with the business of the Great Western Railway Company.

This announcement was received with great regret, and a cordial vote of thanks was afterwards passed to the Chairman and Directors, after which the proceedings terminated.

Liverpool Overhead Railway Company (Limited).

The half-yearly meeting of this Company was held on Tuesday at Liverpool, Sir W. B. Forwood presiding.

The Directors' report for the year ended June 30th, which was given in our last issue, was taken as read.

The CHAIRMAN said the accounts were of a satisfactory and encouraging nature. Their traffic for the first six months had always in their experience been considerably less that that of the second half-year. Therefore they compared their figures with those for the corresponding period of last year. They would notice that their number of passengers had increased from 2,861,437 to 3,460,060 in the past half-year. There had been a very satisfactory increase in the number of first-class passengers from 277,653 to 400,260, and also in second-class passengers from 1,246,975 to 2,114,462. Some remark had been made as to the decrease in the number of workmen's special return tickets during the past half-year; the decrease had been from 1,336,809 to 945,338. This meant a decrease of 391,000. That was no indication of any less traffic by workmen, but it arose from the fact that they now did not issue workmen's tickets after eight o'clock in the morning, and were also charging 3d. for a workman's return ticket instead of 2d., which was their charge a year ago. Therefore, what they were losing in the cheap return tickets by workmen they were getting by the increase in the second-class traffic. There were 391,000 fewer workmen's tickets, but in second-class passengers alone there was an increase of 868,000. Their gross receipts amounted to £28,082, against £20,011 in the corresponding half of last year, an increase of £8,071. The gross expenditure had been £18,658, against £14,947, an increase of £3,711; they had therefore earned an increased revenue of £8,071, of which they had spent in earning it £3,711, part of the expense having gone in increased mileage. The increase in the running was 45,000 miles, and they had worked 16 stations instead of 14, consequently they had had the additional expense of two stations. He was glad to say their traffic had continued to progress since the accounts were made up. During the six weeks which had elapsed since June 30th they had increased their traffic by 55,000 passengers, and had taken £1,568 more money than they did during the corresponding six weeks of last year. The net available profit for dividend was £8,076, and they proposed to declare a 5 per cent. dividend upon their Preference capital, and a dividend at the rate of 2¼ per cent. on the Ordinary shares, leaving a balance of £1,302 to be carried forward. Their receipts for passengers had averaged 1·92d. per passenger, as against 1·65d. This increase, which meant nearly one-third of a penny per passenger, was due to the advance they had made in the workmen's tickets and to the increased first-class traffic upon the line. The ratio of expenditure to their revenue had been 66·43 per cent., as compared with 74·69 for same half of last year. The ratio of the cost of their locomotive expenditure to net revenue was 24·26d., as against 21·28d. That was an increase of nearly 3d. This was due to their having had more repairs to effect to their motors than they had at the similar period last year. The long frosty winter was particularly trying to the motors. The proportion of their travelling expenses to their revenue was 37·54d. against 41·99d. That was also a satisfactory feature, as showing that in proportion to their revenue their expenses had gone down. Their revenue per train mile had increased from 18·10d. to 21·65d, or 3·55d. per cent. The expenditure per train mile had gone up from 2·88 to 3·49, or 0·61 of a penny. With regard to punctuality, he found that during the past half-year 96·8 of their trains were up to time, against 95 per cent. in the previous half-year, and he believed that since they had closed the half-year they had touched a record, that was to say, last week every train on the line was up to time. In reference to the physical condition of their line, it had never been in a better condition than now. The permanent way was in a most excellent state, better in fact than it had been at any time since the line was opened. The contract for the Southern extension, from the Herculaneum Dock, the present terminus, to a point in Park-road near the Dingle, had been let at a figure within the estimate made by their engineers, and the contractors were already very busy at work. The Directors had every reason to anticipate that this new extension would be completed within the twelve months as stipulated by the contract. The thanks of the Directors were due to the shareholders for the way in which they had come forward and taken up all the Ordinary and Preference shares offered them for the purpose of defraying the cost of the extension. The subscription was considerably more than double the shares they had to allot, and they were glad to think they would be able to construct their extension without issuing any bonds whatever. There was every prospect of their traffic being considerably increased by that extension. They were very much indebted to Mr. S. B. Cottrell, their engineer and general manager, and also to his very efficient staff, for the excellent and very satisfactory manner in which they had done their work during the past half-year.

The report and accounts were then unanimously adopted, and a cordial vote of thanks to the Chairman terminated the proceedings.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1895, pages *304-332, &c. &c.*]

KEIGHLEY ELECTRICAL ENGINEERING COMPANY (LIMITED).—This Company was registered on August 12th with a capital of £5,000, in £1 shares, to take over the business carried on by the Keighley Electrical Engineering Company (Limited), at Keighley, Yorks, to undertake the liabilities of the old Company on certain terms and conditions, and to carry on the business of electrical and mechanical engineers, electricians, suppliers of electricity for the purposes of light, heat and power, and manufacturers of and dealers in every description of electrical apparatus. The subscribers, with one share each, are: Messrs. L., J., and J. C. Ickringill, A. D. Smith, J. S. Naylor, C. H. Seed, and C. J. Garnett, electrical engineer.

MACHINERY INSURANCE COMPANY (LIMITED).—This Company was registered on August 8th, with a capital of £200,000, in 195,000 Ordinary and 5,000 Deferred shares of £1 each, to purchase and take over the business of machinery insurance and maintenance now carried on by James R. Fawkner, and to carry on the business of insurers of machinery, ironfounders, mechanical and consulting engineers, manufacturers of agricultural implements and other machinery, tool makers, brassfounders, metal workers, boiler makers, millwrights, machinists, iron and steel converters, &c.

SMELTING COMPANY OF AUSTRALIA (LIMITED).—This Company has been registered with a capital of £500,000, in £1 shares. The Company

Digitized by Google

recently acquired the benefit of an agreement to grant the sole licence to use in the colony of New South Wales the electrolytic process of Messrs. Siemens Brothers and Co. (Limited) for the production of metallic zinc, patents for which are to be obtained by Messrs. Siemens Brothers and Co.

ACME AND IMMISCH ELECTRIC WORKS (LIMITED).—The annual return to July 3rd has been filed. The nominal capital is £25,000, in 20,000 Ordinary and 5,000 Preference shares of £1 each. 19,042 Ordinary and 4,140 Preference shares have been taken up, and the former have been issued as fully paid. A call of 15s. per share has been made on the Preference shares.

CHESHIRE ELECTRIC AND STEAM YACHT COMPANY (LIMITED).—An agreement just made with J. L. Gordon, merchant and contractor, of Liverpool, provides for the sale to this Company of three launches propelled by electric power, fully equipped and furnished, and ready for immediate use for passenger and goods traffic.

DISTRICT MESSENGER SERVICE AND NEWS COMPANY (LIMITED).—The annual return to July 23rd is filed. The capital of £275,000 is divided into 39,800 Ordinary and 200 Founders' shares of £5 each, and 75,000 Preference shares of £1 each. 17,939 Ordinary, all the Founders' and 23,937 Preference shares have been allotted, and of these 12,653 Ordinary, all the Founders' and 182 Preference shares have been issued as fully paid, while 14,818 Preference shares have been issued with 13s. 4d. per share considered as paid. The full amount has been called on the remaining 5,286 Ordinary and 8,937 Preference shares, and 6s. 8d. per share has been called on the 14,818 Preference shares.

MILVER PORTABLE ELECTRIC BATTERY SYNDICATE (LIMITED).—An agreement recently made by this Company with H. Levetus, electro-plate manufacturer, of Birmingham, W. Rowbotham, electrician, of Manchester, and Mrs. Sarah J. Levetus, the vendors, provides for the acquisition of their rights to provisional specifications Nos. 106, 107, 231, and 2,394 of 1895 for "improvements in primary batteries," and No. 7,600 of 1895 for "improvements in and relating to primary batteries," in consideration of £750 in cash, and the allotment of 3,020 fully-paid £5 shares.

OSWESTRY ELECTRIC LIGHTING AND POWER COMPANY (LIMITED).—The annual return to April 9th has been filed. The nominal capital is £10,000, in £1 shares, and 2,021 shares have been allotted. On each of these 2s. 6d. has been paid.

RAND CENTRAL ELECTRIC WORKS (LIMITED).—An agreement recently made with Messrs. Siemens and Halske, of Markgrafenstrasse, Berlin, filed July 5th, provides for the acquisition by the Company of a certain licence or grant from the Transvaal Government, and the benefit of various arrangements with John H. Davies, who is to act as sole agent of the Company for supplying the material and apparatus and erecting the plant requisite for the equipment of the power installations at the various mining companies' works; with the Transvaal Trust Company, for the purchase of an electric generating station site at Brakpan, and with Edward Lippert. In consideration of such transfer the Rand Central Electric Works has agreed to pay £1,000 as a repayment of the deposit to the Transvaal Government, and to allot 19,000 fully-paid shares to Messrs. Siemens and Halske and 1,000 fully-paid shares to John H. Davies or his nominees.

CITY NOTES.

BELFAST STREET TRAMWAYS COMPANY (LIMITED).—At the meeting of this Company on Tuesday the Chairman (Mr. Wm. M. Murphy, J.P.), referred to the question of the adoption of a system of mechanical traction on their lines. He strongly favoured an electrical system, and predicted that in 20 years' time horse trams would be a curiosity. The Belfast Company had only a 12 years' lease, and it would therefore be impossible for them to convert their present system, but they were willing to discuss the matter with the Corporation at any time.

BRIGHTON AND ROTTINGDEAN SEASHORE ELECTRIC TRAMROAD COMPANY.—An extraordinary meeting of the shareholders of this Company will be held at the offices, Madeira-road, Brighton, on 30th instant, to consider the question of an issue of debentures.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended August 11th were £860, against £897 in the corresponding week of 1894, a decrease of £37. The total receipts for the half-year amount to £5,084, against £5,203 for the corresponding period of 1894, a decrease of £119.

GAS COMPANIES' ACCOUNTS.—The sanguine views taken by the chairmen at some gas shareholders' meetings are exhilarating. Mr. E. J. Phillips, who presided over the Newport Gas Company's meeting on Monday, did not think the proprietary had any cause to feel alarmed at the electric light, "as business premises can be better illuminated as a whole by the incandescent gaslight than by electricity." The Chairman of the Chester Company, Mr. J. Gamon, is perhaps not quite so sure that the incandescent gas will prove a saviour. He said the Directors of the Company had not felt justified in incurring expense in the direction of introducing incandescent gas burners, in view of the fact that it was the intention of the Town Council to undertake the lighting of the streets by electricity. If this intention were carried out it would throw on the Company's hands a quantity of valuable plant, and so render unremunerative considerable capital expended for the purpose of public lighting.

GREAT NORTHERN TELEGRAPH COMPANY.—The coupons falling due on September 1st on this Company's 1883 Debentures (Series B) should be presented for payment at Messrs. C. J. Hambro and Son's, 70, Old Broad-street, London, E.C., where lists may be obtained.

GUILDFORD ELECTRICITY SUPPLY COMPANY (LIMITED).—The prospectus is issued locally of this Company. The Board of Directors consists of gentlemen who have substantial interests in the borough, and have been prominently identified with its commercial enterprise. The total share capital of the Company is £20,000, of which £1,500 has been already subscribed by the Directors and their friends. There are 3,900 Ordinary shares of £5 each, and 500 Founders' shares of £1. The subscription list closes on the 19th inst. Figures are given showing an estimated profit available for dividend of about 9 per cent. on the present issue.

IMPERIAL TRAMWAYS COMPANY (LIMITED).—The half-yearly report of this Company, just issued, states that owing to various stoppages of traffic on certain sections of the Dublin Southern District Tramways Company's lines, in which the Imperial Company are greatly interested, and to the disorganisation naturally caused by the introduction of a system of electric traction, the past half-year's figures cannot be compared with those for any previous half-year. The contract for the electrical reconstruction of the tramways provided for the completion of the portion from Dublin to Kingstown by May 1st, and from Kingstown to Dalkey by July 1st, but the contractors have been unable to complete the works within the stipulated periods. The Company has, therefore, been debarred from securing the summer traffic, and the contractors have agreed to contribute a specified sum in satisfaction of the Company's claim to June 30th. The permanent way reconstruction and electrical equipment of the lines between Dublin and Kingstown are well advanced, and work on the Dalkey section will shortly be commenced.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended the 11th inst. amounted to £1,578. The amount for the corresponding week last year was £1,257; increase, £321.

MANCHESTER EDISON-SWAN COMPANY (LIMITED).—The Directors of this Company have declared a dividend at the rate of 5 per cent. per annum for the past year. The gross profit amounted to £5,877, and the net profit to £1,590. £591 has been placed to the credit of the depreciation account, and a sum of £287 carried forward.

MACHINERY INSURANCE COMPANY (LIMITED).—This Company has issued its prospectus inviting applications for 95,000 Ordinary and 5,000 Deferred shares of £1 each, payable 2s. on application, 2s. on allotment, and the balance in 2s. calls at intervals. The nominal capital is £200,000, divided into 195,000 Ordinary shares and 5,000 Deferred shares of £1 each. The Company has been formed for the purpose of developing a system of machinery insurance and maintenance. The Company's prospectus includes the machinery employed in the following branches of industry as coming within the sphere of its operations:—Electric lighting, engineering tools, brass finishing, metal working, chemical works, pumping, hoisting, &c. The Company's scheme does not include the insurance of boilers. The consulting engineer to the Company is Prof. A. B. W. Kennedy, and the general manager is Mr. J. R. Fawkner, whose original business forms the nucleus of the Company's undertaking. The secretary is Mr. W. E. Duncan, and the offices *pro tem.* are 19 and 21, Queen Victoria street, London, E.C. The subscription lists opened yesterday (Thursday), and will close on Monday for town and country. With careful management and a moderate scale of premiums there should be a useful and fairly profitable future before the Company.

MERSEY RAILWAY COMPANY.—At the half-yearly meeting of this Company last week the chairman (Mr. A. K. Kitching) stated that since the date of the last meeting the Directors had made inquiries as to the working of the railway by electricity or other motive power, and had decided to proceed with the Company's Bill in Parliament for the necessary powers. This Bill had passed the Committee of the House of Commons. What the Board originally proposed in the Bill in relation to the finances of the Company had been very materially modified owing to the action of the debenture-holders, and the Act only now asked that the Company should be allowed to work the line by electricity.

MORECAMBE ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—An extraordinary general meeting of the shareholders of this Company was held on Saturday last to receive and consider a statement of the Company's affairs. After this had been discussed it was unanimously resolved that the Directors be empowered to treat with and enter into an agreement with the District Council, or any other intending purchaser, for the purchase and transfer of the Company's undertaking and property.

NORTH STAFFORDSHIRE RAILWAY COMPANY.—At the meeting of the shareholders on Monday Mr. T. Salt, the Chairman, stated that the Directors had recently introduced the electric light at Stoke, their principal station. They had lighted up a large goods yard and warehouse, and the electric light had proved the very best light they could use, both for convenience and for the safety of the men who were employed at night. The light had been very successful, and the result was that they not only got a much better light, but also a cheaper light. He was not prepared with the exact figures of cost, but he was assured that these which were being prepared would prove convincing as to the wisdom of the course taken by the Directors.

SMELTING COMPANY OF AUSTRALIA (LIMITED).—Letters of allotment and regret in the recent issue of capital of this Company have, it is stated, been issued.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended 9th inst., after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,725.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 901. [No. 17. Vol. XXXV.] FRIDAY, AUGUST 23, 1895. PRICE SIXPENCE.

NOTES.

"PRACTICIANS" who may have been sufficiently courageous to glance at and sufficiently persevering to master the contents of Dr. LODGE's Report to the Electrical Standards Committee, which we published in our issue of August 2nd, will, we think, agree with the opinions expressed by Prof. SILVANUS THOMPSON with characteristic lucidity and point, in his letter to be found this week in our "Correspondence" columns. Prof. THOMPSON's dictum that the adoption of units likely to be used by practical electrical engineers is more important than names, and a common agreement between theorists and "practicians" more important than a scientifically ideal system, is instinct, to use his own phrase, with "elementary common sense." To us, the hankering after names evinced by so many on either side of the Atlantic is somewhat of a puzzle. N = 1,000,000 conveys, one would have thought, quite as much as N = 1,000,000 "thoms"; and there is no need to remember which mutilated surname we ought to apply. However, be this as it may, we trust dynamo-designers and others will follow Prof. THOMPSON's advice, and either discuss the many *pros* and *cons* of this question in the columns of the technical journals, or put in an appearance next month at the British Association, and take part in the proposed discussion. Above all things let us hasten slowly, but adhere doggedly to whatever is once definitely decided on in the matter of magnetic symbols, nomenclature, units, and definitions. Practical men cannot be for ever discarding what is good enough for what is better still.

A NEAT and useful piece of work has been done by Prof. IHLE on the conditions governing the action of nitric acid as a depolariser in a cell of the Grove type. The method of experimenting and the conclusions arrived at will be found in another column, and it is sufficient to say here that the views put forward are consistent with what is known of the behaviour of nitric acid towards oxidisable metals when no question other than those purely chemical is raised. It is now recognised that the presence of nitrous acid is necessary for the attack of a metal such as copper by nitric acid, and the case has been duly covered by the blessed phrase "catalytic action." The voltage given by a Grove cell is reduced to that of a plain zinc-platinum couple without a depolariser (such as our venerable friend the Smee cell), when for any reason, the nitric acid in the platinum compartment is free from nitrous acid. This merely means that whereas the high voltage of a normally-working Grove cell is due to the oxidation of the hydrogen which would be liberated at the platinum plate were nitric acid absent, nitric acid free from nitrous acid is incapable of oxidising that hydrogen, and the voltage is, in consequence, diminished by a quantity represented by the non-oxidation of the hydrogen. The hydrogen acts precisely in the way characteristic of metals which resist nitric acid *per se*, but succumb when nitrous acid is also present. It would have been interesting if Prof. IHLE had recorded the appearance of hydrogen on the platinum plate whenever the voltage fell to the lower limit, but no direct observation appears to have been made.

IN another column will be found M. ANDREOLI's reply to Mr. STEPNEY RAWSON's letter on the subject of "Indirect Electrolysis," which we published last week. From M. ANDREOLI's account of his experiments we should not have supposed that any phenomena had occurred which could not be accounted for by the ordinary modern theories on the subject of electrolysis; but as no data as to the resistance of the bath, or the current density, or the E.M.F. employed are given, it is not possible to form any definite opinion. M. ANDREOLI accepts, we understand, the ionic hypothesis of the transfer of electricity through an electrolyte, and he is aware of the text-book statement that if a plate of metal is suspended in an electrolytic vessel when the current is passing, the current enters the plate on one side and leaves on the other. This being so, it is natural that the side facing the anode should act as a cathode. It would appear to us that this is just what happens in the case of the experiments described by M. ANDREOLI. As we have stated before, the data on which to form an opinion are incomplete, but as the process described forms the subject of Eng. Pat. 4,393, 1895, doubtless we shall hear more of the matter.

WHEN an electric supply station is situated in a residential district, and its chimney persistently belches forth injunction-raising smoke, it will be conceded that, for the time being, the suppression of the nuisance, in a manner which will not hamper the working of the station, is of more importance than mere economy. Either the smoke alone, or smoke and station altogether must be stopped. In such a predicament engineers have been put to the trouble of trying all manner of smoke-consuming apparatus; some, of these grossly uneconomica

Digitized by Google

and unsatisfactory; some the former but not the latter; and and some which, with special coals, however, will not only remove the nuisance, but, happily also augment the dividends.

INVENTORS of smoke-consuming devices are not, as a class, content merely to whisper the merits of their wares; and it is not uncommon to hear one man proclaiming as his triumphant remedy the very thing which another will tell you is the chief cause of the trouble. With all this, we are still troubled with smoky chimneys; and, indeed, are likely to be to the end of the chapter, or as long as bituminous coal is burned in boiler furnaces. The latest remedy proposed consists in a device for removing solid matter from the products of combustion, by means of a cold water spray at the base of the chimney. The soot goes away in the water and is afterwards collected, while the gases are cooled to about 150°F. As this temperature is too low to give a natural draught, a fan is placed at the bottom of the chimney; and the water spray, directed on to the fan, serves to keep the apparatus comparatively cool and clean. Since, as we have already said, questions of economy are occasionally of secondary importance, it is perhaps hardly fair to ask what the working of all this is going to cost. We understand that the apparatus is the invention of Mr. J. PATERSON, of Glasgow; and we feel quite safe in saying that with a sufficiently copious spray of water all the soot will be taken out of the gases. But, for the rest, we await the results of the forthcoming tests.

OF the feats performed on American electric railways there is no hearing the end. The latest is the performance of the cars on the Nantasket Beach branch of the New York, New Haven and Hartford Railway. Accounts differ as to what the cars actually did do; some papers stating that a speed of 80 miles an hour was attained "with the juice not fully turned on," while others more moderately limited it to from 30 to 50 miles. Naturally we should expect to find this performance took place on a long length of good and fairly straight railway. But no; the entire length of the track was only 6·91 miles—the second place of decimals is convincing—and of this "there are 4·4 miles of curves in about 20 curves, the sharpest being one of 10 degrees." And the track was laid with mere 70lb. rails, about which nothing special is to be noticed, save the absence of anything special. Yet, we are assured, it has been calculated—for actual speed measurements do not seem to have been made—that during the tests single motor cars have been run at 80 miles an hour; while a train of 40 trailers drawn by one 4-motor car attained a speed of 40 miles an hour "past the visitors." We do not know if the visitors made the calculations, nor whether a slide rule was used in the process; but we humbly suggest that possibly there is something wrong with the decimal place.

Electric Traction in Genoa.—The necessary approval having been given to the plans, work is about to be commenced at Genoa on two lines of electric tramway.

Tory Island Cable.—It is stated that the Government have entered into negotiations for the purchase of the cable laid some years ago by Lloyd's Committee between Tory Island and the mainland.

Cable Interruptions and Repair:—

	Date of Interruption.	Date of Repair
Accra-Kotonou	August 9th.	August 17th
Accra-Lagos	August 12th.	—

Electric Light on German Lighthouses.—The authorities for lighthouses in the Bremerhafen district have resolved to provide the lighthouse on the island of Wangeroog with an electric light installation. It is also under consideration to run a submarine cable to the lighthouse of Rothensande, at the mouth of the river Weser, for the purpose of lighting the same electrically. A survey of the place is now being made by the steamship "Weser."

Lightning.—Yesterday morning a heavy thunderstorm passed over London. There were also severe storms in other parts of the country. At Hampton a man, sheltering beneath a tree, was killed, and two children appear to have been struck down, but without serious injury. Near Loughborough a man and horse were killed, the man having been driving the horse in a cart. On Saturday last lightning fired a haystack in a field near Dover.

Electric Traction in the Suburbs of Berlin.—According to the latest reports from Germany the Allgemeine Elektricitäts Gesellschaft is about to erect extensive electric plants for lighting and traction purposes in the districts of Teltow and Niederbarnim, in the vicinity of Berlin. It is intended to build a whole network of tram lines connecting about five villages with each other, and also with the German capital. The preparatory work has already commenced, and the completion is expected in 1896.

Utilisation of Water Power in Italy.—Plant is being established at Castellamontel (Ivrea) by Messrs. Siemens and Halske, of Berlin, for the utilisation of the water power of the Chinsella torrent. The plant, when completed, will include three turbines of 750 H.P., constructed by Messrs. Riva, Monneret and Co., of Milan, and three alternators. The electrical energy generated will be transmitted to Strambino, Ivrea, St. Georgio, Rivarolo, Canavese and Brellà, the latter town being 37 kilometres distant from the station, for lighting and power purposes. The plant has to be in operation by July 1, 1896.

Stellar Gaseous Elements.—Mr. Norman Lockyer has reported to the Académie des Sciences that upon heating minerals of various kinds in vacuum traces of gas are given off, which exhibit, upon spectroscopic examination, lines not hitherto observed in any of the terrestrial elements. He finds, for example, lines which have hitherto only been found in the spectrum of parts of Orion and of the chromosphere of the sun. Evolution of gas takes place in this way in every mineral yet experimented upon.

The Municipalisation of Tramways.—The accounts of the Tramways Committee of the Glasgow Corporation for the eleven months ending May 31st last showed a net profit enabling £8,260 to be transferred to the "common good." In *The Times* of Tuesday Mr. Joseph Ebbsmith points out in a letter of some length that on the figures submitted by the Tramways Committee themselves, the Glasgow experiment in Municipal Tramways must result in an average net loss of not less than £20,000 per annum. Here are some of the allegations:—

> Out of a stud of 3,694 horses purchased up to May 31, 1895, 250 had died or been sold during the 11 preceding months, and the loss upon them had been £6,427. The value of the stud stood at £117,337. The average life of a tram horse is five years. The provision for depreciation on horses made by the Tramway Committee was £4,145! Again, a reference to capital account shows that the expenses of preparing horses for work were more than £13,000, but no part of this sum—or, indeed, of the general preliminary charges, amounting to £38,992—was, so far as I can trace, charged against the revenue account.

The Salford Municipal Station.—The following particulars with regard to the electric light works of the Salford Corporation, which were formally opened on the 7th inst., may be of interest. The Council have spent, or shortly will have spent, a grand total of £34,338 on the works, acting on the advice of Messrs. Kincaid, Waller and Manville. The high-pressure alternating system has been adopted, the current being supplied, at a pressure of 3,000 volts, through concentric cables laid in cast-iron pipes to house transformers. There are three sets of

Digitized by Google

engines and dynamos at the generating station, each set capable of supplying 2,500 8 c.p. lamps. The engines are of the slow-speed horizontal compound-condensing type, working at 160lb. pressure, and running at 85 revolutions. These engines drive Mather and Platt alternators by means of cotton ropes. There are three Lancashire steel boilers, fitted with mechanical stoking appliances, economisers, &c. The fuel to be used in them is coke from the Corporation gas works. From trials that have been made it has been found that not only has gas coke the great advantage of being a clean, smokeless fuel, but it is a very economical one for steam boilers. At the present time the Corporation have 19 customers, who have altogether about 1,000 lamps, and there are applications from others for a supply for about 500 additional lamps. The charge for current is at present 7d. per unit.

Self-Propelled Road Carriages.—The following important notice appeared in the editorial column of the *Engineer* of the 16th inst.:—

"We have offered for competition prizes to the value of one thousand guineas for self-propelled road carriages, believing, as we do, that the construction of such carriages may very well constitute a new branch of manufacture at least as important as that of cycles, which in a very few years has attained to enormous proportions. But it is obvious that unless the use of vehicles propelled by steam, oil, gas, or electricity is sanctioned by the Legislature, no progress can be made in this direction. It will be remembered that an alteration in the existing Highways (Locomotives) Act was prepared and met with favour in the late Parliament, and would probably have become law but for the dissolution. It is most desirable that the existence of a demand for such a change should be brought to the notice of the new Government, and to that end we have prepared the subjoined memorial, a copy of which lies at our office for signatures. We may add that those of our readers in the country who are interested can have a copy of the memorial forwarded to them for signature on application to our publisher. Energetic action at the present moment will be of far more value than at a subsequent period when Parliament becomes engrossed with matters which, however important for the nation in general, have scant interest by comparison for engineers."

Then follows the text of the petition, which is addressed to the President of the Local Government Board, and which requests that the Bill introduced to Parliament under the late Government, or some similar Bill, "may be presented to Parliament with the least possible delay."

Magnetic Units.—Commenting upon the Report by Dr. Oliver Lodge on "Magnetic Units," published in *The Electrician* of August 2nd, our contemporary the *Electrical World* of New York says:—

"Though the question of scientific units is essentially an international one, the English writer proceeds to consider it as if its geographical boundaries were those of the British isles and that, perforce, all other countries would, willy nilly, have to accept the English solution. Notwithstanding the adoption and definition by the Chicago International Electrical Congress of the henry as the unit of inductance, and its legalisation by act of Congress in this country, the Paper merely states that 'It has been practically decided in America that this unit shall be named after Prof. Henry, of Washington, but the precise definition has not yet been agreed upon.' This is the only reference in the Paper to any non-English action on the question of units, and 'Prof. Henry, of Washington,' is the only non-English name mentioned. Though recognising the name 'henry,' the Paper suggests as a value for unit inductance, 10^9 times the C.G.S. unit, the present value of the henry being 10^8 C.G.S. units. It very fortunately happens that the suggestions of Prof. Lodge will have to stand criticism before the B.A., and, still more fortunately, that final action in the question of units will rest with Kelvin, Rayleigh, J. J. Thomson, Ewing and others, who will be inclined to take the liberal view of the subject which its nature demands. Prof. Lodge in his Paper states that, 'It need hardly be said that in the last resort it rests with practical men to employ or decline any suggested system of units.' What fate, at the hands of the 'practical men' of the United States, France and Germany, would be met by a system of units devised in a spirit of insular 'jingoism' and promulgated as by a lordly estate to an inferior order?"

Electricity in Parliament.—According to an American technical journal, the present system of voting in the House of Representatives will be abolished before long, and electricity will take its place. The first step toward such a plan already has been taken in the abolition of the old method of calling pages in the House. Hitherto the member who wanted a page had to clap his hands until a boy came. This kept some 10 or 15 boys always waiting on the edge of the speaker's dais. This had proved to be a nuisance long enough, and it has been done away with. Each congressman's desk is now provided with an electric button which communicates with an ordinary hotel annunciator in the lobby. As it was impracticable to attach the wires to the desk permanently, an improvement has been made which permits of the removal of every desk in the place without trouble. Brass plates have been let into the floor, and upon these the legs of the desk stand, being provided with metal contacts. Connection is made through the plates. The new plan will keep the boys out of the House and insure better service than under the old plan. It will also act as the entering wedge for the idea of voting by electricity. It would be easy enough to put buttons upon the desk of each member which would electrically record his vote. Those who favour the plan say that the recording board could be in full view, and that fraudulent voting would be impossible.

The British Association.—The arrangements for the meeting of the British Association at Ipswich are, says *Nature*, making rapid progress. The reception room will be located in the Town Hall, the council chamber being the room actually set apart for the purpose, whilst the library will be the writing room. The President's address and the evening discourses will be delivered in the public hall, as will also the lecture to working men. In the matter of Section rooms, there are fortunately a number of suitable rooms and halls in the town within a very short distance of each other, and all are close to the reception room. The two halls at the Girls' High School, which were formerly the New Assembly Rooms, will be allotted to Section A and Section B. About 200 yards distant is the Co-operative Hall, in which Section G will meet. The proceedings will commence on the evening of Wednesday, Sept. 11th, when the Marquis of Salisbury will retire from the presidential chair, and Sir Douglas Galton will take his place. The new President will then proceed to deliver his address. On Friday evening Prof. Silvanus Thompson will deliver a lecture on "Magnetism in Rotation." The lecture to working men will be given on the Saturday evening by Dr. Alfred H. Fison, who takes "Colour" for his subject. The hon. local secretaries for the meeting are Messrs. S. A. Notcutt, G. H. Hewetson, and E. P. Ridley. All communications to them should be addressed to the Museum, Ipswich.

Magnetic Observations.—The results of some observations on declination made by M. Ch. Lagrange, which, if unaffected by some unsuspected error, are most unexpected, are, says *Nature*, given in a recent number of the *Comptes Rendus* (June 17, 1895). During the last three years the author has been making observations of declination at the Uccle Observatory at Brussels, using for this purpose magnets having very different magnetic moments. He finds that systematic differences occur in the values obtained; but what is most astonishing is that diminution, within certain limits, of the magnetic moment of the magnet causes an amplification of the observed changes in declination. In one set of observations, lasting for six months, one of the magnets consisted of the almost astatic magnetic system taken from a galvanometer. By comparing the readings obtained with this system of magnets with those obtained on the self-registering magnetometers, it was found that the amplitude of the movements of the galvanometer needle was from 15 to 25 times as great as that of the magnetometer needle. Another set of observations has been made with a large steel magnet, only feebly magnetised, however, so that its magnetic moment was only about $\frac{1}{10}$th of that of the magnet of the magnetograph. This magnet was suspended by a fine platinum wire, and here again the amplitude of movement of the feebly magnetised bar was greater than that of the more strongly magnetised one.

The Ohm Statue at Munich.—On July 5th, during the third annual meeting of the Verband Deutscher Elektrotechniker at Munich, a statue of Ohm was unveiled in presence of a large number of members of the Verband. The statue is of white marble, and stands in the square in front of the Technical High School. Around the pedestal there are figures in relief. There is also an inscription to the effect that the statue has been "erected by his admirers and disciples." Funds were raised by subscriptions, the first appeal for which was made six years ago, on the occasion of the 100th anniversary of Ohm's birthday, to which England, France and America liberally responded. In all £2,000 was subscribed. The statue was designed and cut by Profs. von Thiersch and von Ruemann after an old photograph and a painting of Ohm

Digitized by Google

in the possession of the Academy of Science, and from description furnished by still living friends. Ohm was born at Erlangen on March 16, 1789. He was the son of a master locksmith, who was able to teach his sons mathematics. Ohm's first post was that of teacher of mathematics and physics in Gottstadt and Neuenburg in Switzerland. Thence he returned to his native town and acted as *privat-docent* at the university there for a short time. From there he went to Bamberg, and later to Cologne, where he published his chief work, "The Galvanic Circuit Mathematically Elaborated." Later on he became a professor at, and ultimately rector of, the Polytechnic at Nuremberg. He was 60 years of age when he came as professor to Munich, where he worked until his death on July 6, 1854.

The Hodgkins Fund Prizes.—*Nature* publishes the reports of the committee appointed by the Smithsonian Institution to award the Hodgkins Fund Prizes. The report states that 218 Papers were submitted in competition. The first prize, of £2,000, for a treatise embodying some new and important discoveries in regard to the nature or properties of atmospheric air, is awarded to Lord Rayleigh and Prof. William Ramsay for the discovery of argon. The second prize, of £400, is not awarded, owing to the failure of any contestant to comply strictly with the terms of the offer. The third prize of £200 is awarded to Dr. Henry de Varigny, of Paris, for the best popular treatise upon atmospheric air, its properties and relationships. The following receive honourable mention, with silver medal, for their Papers:—Mr. A. L. Herrera and Dr. Vergara Lopez, of the city of Mexico—"La Atmosfera de las Altitudes y el Bienestar del Hombre"; Mr. C. L. Madsen, ("Geo") Helsigór, near Copenhagen, Denmark; Mr. F. A. R. Russell, of London, vice-president of the Royal Meteorological Society of Great Britain—"The Atmosphere in Relation to Human Life and 'Health.'" Among the other awards Mr. Hiram S. Maxim receives honourable mention, with bronze medal, for his Paper, "Natural and Artificial Flight"; and Mr. E. C. C. Baly, University College, London, is awarded honourable mention for his Paper, "The Decomposition of the Two Constituents of the Atmosphere by means of the Passage of the Electric Spark."

Electrolytic "Parting" of Gold and Silver.—The German Gold and Silver Separation Works at Frankfort are using an electrolytic method of "parting." According to ordinary modern practice, the separation or "parting" of gold and silver is effected by boiling the granulated alloy with strong sulphuric acid, in which silver is soluble, while gold is unattacked. This method has almost entirely displaced the time-honoured process of parting with nitric acid, its smaller cost being a tangible advantage, even when dealing with raw materials as valuable as the precious metals. It has now a competitor, actually working on a commercial scale, in the electrolytic process about to be described. The auriferous silver to be parted is cast into plates, which are enclosed in linen bags and made the anodes in a weak solution of silver nitrate made acid with nitric acid. The cathodes, which are thin plates of fine silver, are suspended, without covering, in the bath, and below them is a tray, the bottom of which is of linen. Seeing that there is no difficulty in melting finely-divided silver into an ingot without loss, there is no need to endeavour to precipitate the metal upon the cathodes in a coherent form; thus it happens that a high current-density can be used and the silver deposited pell-mell, scrapers being employed to sweep it down from the cathodes into the tray at the bottom of the bath, and prevent the occurrence of a short circuit. The linen bags containing the anodes are emptied of their residual gold once or twice a week, according to the richness of the alloy treated. Copper which may be present in the original alloy, remains in solution as nitrate, provided a little fresh nitric acid be added to the electrolyte from time to time.

Electric Power in a Hungarian Mine.—At the Kremnitz Mine, belonging to the Hungarian Government, a plant, says the *Engineering and Mining Journal*, has been put down for the electrical transmission of power to be utilised for the operation of a winding engine and a stone-breaking machine. A turbine is used to furnish motive power, and some difficulty was experienced owing to the variation of the load on the turbine. The winding engine had to lift a net load of 15cwt. at a speed ranging from 3ft. to 5ft. 6in. per second, and it was required to drive this engine by means of an electric motor having a normal performance of 45 H.P., and to simultaneously actuate the stone-breaker by a second electric motor. The greatest demand for power is at the moment of taking up the load, and the power required attains various values according to the relative positions of the two ropes, ceasing the instant the cage reaches the surface. After the cage has been brought to rest after the lift has taken place, it has to be lowered a few centimetres upon a given signal. Then, before lowering the empty cage, it has to be raised the same distance, be stopped, and then, on the signal being given, it is allowed to descend. Therefore, within a comparatively short space of time, very wide changes in the load upon the electric motor take place, and these variations were very noticeable in the generating station. The turbine runs at 150 revolutions a minute, under a head of 67ft. water, and it drives a countershaft, from which a dynamo is belt-driven at 500 revolutions. The dynamo has an output of 150 amperes at 350 volts. The turbine was regulated by a centrifugal regulator. It was found when there was no load upon the generating dynamo the turbine raced, the regulator only coming into action when the demand for power reached 12 H.P., and then was not sufficiently precise. An artificial load was therefore inserted so as to keep the speed of the turbine practically constant under variable loads. The idea was that the dynamo should be loaded artificially in such a manner that this artificial load would diminish as the useful load came on and increased, and that it would be entirely taken off when the useful load reached or exceeded the value of the artificial load. For the latter a liquid resistance was selected on the ground of cheapness and sparklessness. The whole arrangement is automatic.

An Electrolytic Forge.—A recent number of the *Electrical Engineer* of New York contains an account of an electric forge, worked on the principle first utilised by Messrs. Lagrange and Hoho, which has recently been put into operation at a blacksmith's shop at Niagara Falls. The principle referred to consists in the heating of the metal to be worked, by immersing it in acidulated or salted water while forming part of the circuit of a powerful continuous current dynamo. It is found that it takes from eight seconds for a piece of iron one quarter of an inch square cross-section, to one minute for a piece one inch square; the latter required 26 amperes at 220 volts, which costs, it is claimed, less than a quarter of a cent. for current. The cost of preparing a horseshoe with a coal forge, with coal at £1 per ton, is 5·58 cents; with the electric forge, and current at 15 cents per unit, it is 2·32 cents. The forge consists of a rectangular wooden tank, with a float controlled by a handle and rack-work for raising or lowering the surface of the liquid. The positive wire is attached to the lead plate suspended from the edge of the tank. The negative wire is connected to three work rests; two of these are used for heating articles held by tongs, such as horseshoes, bolts, rivets, &c., and the other for heating particular points on a long bar of iron. This last is accomplished by laying it in a trough on two pieces of movable firebrick, which can be separated to any required distance. The space between the two bricks determines the length of the part of the rod that will be heated, and can be regulated so as to heat a space on the rod from one-fourth of an inch in length up to the full width of the tank. When the piece of iron is in position, and the bricks are adjusted, the clamps are brought in contact with the iron; on depression of the float the solution is brought in contact with the iron; electrolysis takes place, and the heat due to the high resistance is imparted to the iron. By moving the float up and down, the circuit can be made and broken at will, and in an irregular-shaped piece of iron this gives the heat a chance to distribute itself throughout its mass. The solution used in this forge consists of washing soda 10lb.) borax 1½lb., in 45 gallons of water. The burning hydrogen has the colour of burning sodium, indicating that some of the constituents of the electrolyte are gradually consumed; these must be replaced, and cost about 10 cents per month.

PHASE DIFFERENCE IN ALTERNATE-CURRENT ELECTROLYSIS.

BY W. R. COOPER, M.A.

Theories of electrolysis by alternating currents have from time to time been put forward by Mengarini and others, who have shown that a difference of phase between current and E.M.F. should result by the introduction of a voltameter into an alternating-current circuit, and certain experimental evidence has been brought forward in favour of this view. In the *Elektrotechnische Zeitschrift* for June 6, 1895, Herr Peukert describes some experiments carried out with the object of directly investigating whether any such phase difference does exist.

For this purpose a current of 3·3 amperes was passed through a voltameter, containing acidulated water, in series with a hot-wire ammeter and a carbon resistance, free from self-induction. The current was supplied by a Siemens alternator, separately excited, and was maintained of the same strength throughout the experiments by varying the excitation. A constant speed was also obtained, with a frequency of 96 ∿, by employing an electromotor to drive the alternator. The values of the potential difference at the terminals of the voltameter and the current at any time were found by the well-known method of a Joubert disc revolving with the shaft of the alternator. The potential difference was measured directly, and the current by the fall of potential along a non-inductive resistance. The deflections of the Wiedemann galvanometer employed for the purpose were plotted without further reduction.

Platinum electrodes, each 5·5 x 9cm. were first employed. In order to determine the effect of varying the current density, a platinum strip 11 x 9cm. was used as one electrode, whilst a platinum wire 1mm. in diameter, of which 9cm. were immersed in the electrolyte, was used as the other. Carbon electrodes, in the form of arc-light carbons, one being cored and the other uncored, were also made use of.

From the curves which are given in illustration of the results, it appears that practically no difference of phase was introduced in any of the three cases.

That the experiments are insufficient to disprove the existence of phase difference under all conditions is pointed out in the *Elektrotechnische Zeitschrift* for June 20th by Herr Dolivo-Dobrowolsky, who contributes an article dealing somewhat fully with the matter, which we will here briefly reproduce. It may be shown in a simple manner that a phase difference must theoretically exist where polarisation takes place. If a current, in traversing a circuit, creates an E.M.F., a certain amount of energy is absorbed, apart from that due to ohmic resistance; and, if the current is changed in strength or is reversed, a part of this energy is restored. Thus in the case of an alternating current a definite amount of energy becomes oscillatory. The smaller the resistance the more nearly will the energy given to the circuit be equal to that which is returned; and, in the limiting case, when the resistance is zero, there will be no loss of energy: the current will be wattless, and therefore in quarter phase with the potential difference. If, in the usual manner, the potential difference is resolved into two components, viz., the watt component due to the ohmic resistance and the wattless component due to the E.M.F. created by the current, these components being at right angles, the phase difference ϕ will be given by the relation

$$\tan \phi = \frac{\text{wattless component}}{\text{watt component}}.$$

This formula is known to hold good for coils and condensers, provided we deal with simple sine functions.

In the case of a voltameter, polarisation sets in as soon as a current passes; energy is absorbed, the cell acting as a condenser or a coil, and the potential difference may again be resolved into a watt component due to ohmic resistance, and, at right angles to this, a wattless component, due to the E.M.F. of polarisation. The latter has a limiting value, which for platinum electrodes in acidulated water amounts to about 2·5 volts. To obtain the pure phenomenon it is therefore necessary to keep below this limit, just as it would be necessary to keep below the saturation limit of iron in a corresponding experiment with the self-induction of a cored coil.

In his experiments Herr Peukert mentions the strength of current employed; but he gives no information about the value of the potential difference, or the resistance of the cell—data of far greater importance, since the phase difference directly depends upon them, and may have a very small value unless the conditions are suitable. For example, suppose the impressed potential difference at the electrodes amounted to 50 volts, and that due to polarisation had a mean value of 1·5 volts, then $\sin \phi = \frac{1\cdot5}{50} = 0\cdot03$. This corresponds to so small an angle that it would not be observed by direct curve measurements. In order that a large phase difference should result, the potential difference loss due to ohmic resistance must be small compared to the E.M.F. of polarisation. Now, to produce a certain value of the polarisation, a definite mean-current density in the electrodes is necessary. The resistance must not, therefore, be diminished by increasing the size of the plates, since the current would then require to be increased to obtain the same polarisation, and the ratio of the two potential-difference components would remain unchanged. Any diminution of the resistance must be effected by bringing the electrodes nearer to one another.

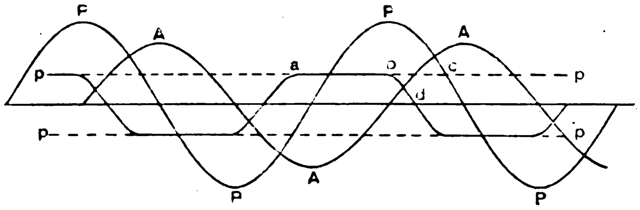
Having regard to these precautions, Herr Dobrowolsky mentions, in conclusion, that he has obtained a phase difference of over 80deg. with batteries of iron plates in solutions of soda, and has also reproduced the capacity phenomenon of the Lauffen-Frankfort conductor with low-voltage currents. For example, if a weakly-excited alternator is put in circuit with a polarisation battery, a rise of potential difference takes place of from 50 to 100 per cent. Self-induction has also been balanced against polarisation by Stanley; and Brown has employed a polarisation cell for the production of a phase difference required in starting his alternate-current motors. Thus both theory and practical experience indicate that a phase difference is always produced.

It is scarcely necessary to remark that such investigations have a practical bearing upon the testing of alternators, for which purpose a water resistance is often made use of on the assumption that it is equivalent to a non-inductive resistance. Barrels and sheet lead are generally at hand, so that such a method is particularly convenient for a trial run after the erection of an alternator. But does the product of volts and amperes give the power expended as accurately as may be required? In certain cases it evidently does so, and indeed it does not appear probable that serious error would arise in practice, provided the electrodes are so placed that the loss of potential difference through ohmic resistance is large compared to the polarisation. In other words, the number of tubs in series should be as small as possible, and the electrodes should be far apart with a high current density.

Alternate-current electrolysis presents a field for experimental research, which, under favourable conditions, should yield results of considerable interest, though perhaps not of much commercial value. Mengarini placed polarisation in the same category as self-induction, but there seems very little doubt that it acts in a way analogous to capacity, as pointed out by Herr Dobrowolsky, though in a less simple manner. A good deal must depend upon the magnitude of the impressed potential difference. If that is below what is required to effect decomposition, then a voltameter would be expected to act simply as a condenser. If it rises above this critical value, but does not exceed the limiting value of the E.M.F. of polarisation, there would be a condenser effect followed by a polarisation effect every alternation, giving rise to a potential difference in quarter phase with that due to ohmic resistance. Lastly, if it exceeds the E.M.F. of polarisation, the changes in the last case are followed at the end of each alternation by a period during which the products of decomposition are readily evolved, if gaseous; but in this case the resulting potential difference is not simply in quarter phase with the other component. Disregarding, for the moment, capacity and the critical value of the potential difference necessary to break up the electrolyte, let us suppose that a current, represented by the curve A in the usual manner, is flowing through the voltameter. If the impressed E.M.F. does not exceed the limit of polarisation, the latter gives rise to an opposing E.M.F. which may be represented by the curve P, in quarter phase with A and with

Digitized by Google

the component due to ohmic resistance. Now let the impressed E.M.F. be greater than the limit of polarisation, which limit we will suppose to be given by the lines *p p*. The curve *p* in this case cannot rise above *p p* on either side of the axis of time. There are therefore periods during which the polarisation has a steady value, as indicated by the continuous parts of *p p*, such as *a b*. But this does not continue to the point *c*, where *p p* cuts the curve *p*. As soon as the current falls to a zero value the polarisation will begin to diminish. It will become zero when the quantity of electricity passing, since the reversal of the current, is equivalent to the products of decomposition upon the electrodes; and the polarisation curve will cut the



axis at a point *d*, after which it will pass on to a steady maximum of opposite sign. Thus a wave is produced which is displaced from the position of *p*, the extent of the displacement increasing as the current density in the electrodes increases. The resulting component of the potential difference is no longer in quarter phase with that due to ohmic resistance, and, in the limit, when the current density is very high, the phase difference between current and impressed potential difference vanishes, the two components being in opposition.

THE ACTION OF NITROUS ACID IN A GROVE CELL.

A Paper on this subject was recently read before the German Electrochemical Society by Prof. Ihle, who touched upon the following interesting points:—

A Grove cell having in the platinum compartment nitric acid of a strength corresponding with a content of 38 per cent. of HNO_3 possesses a voltage which is that characteristic of a nitric acid cell (about 1·8 volt), and is sensibly constant. If the nitric acid be further diluted, the cell exhibits, if only for a very short time, a voltage proper to a cell of the Smee type, viz., 0·7 volt. As the strength of the nitric acid is decreased, the time during which the cell retains the lower voltage increases, until at a strength of 27-28 per cent. HNO_3 the lower voltage is permanent.

The observation of this alteration of voltage may be conveniently made by filling a battery glass with dilute nitric acid, and placing two small porous cells therein, the one containing an amalgamated zinc rod in a solution of zinc sulphate, and the other a platinum plate in nitric acid of the required strength. Working with an arrangement of this kind it can quickly be demonstrated that the voltage of the cell depends upon the nitrous acid originally present in the nitric acid or formed during the action of the cell while the circuit is closed. For example, using nitric acid of a strength below that represented by 28 per cent. HNO_3, so that the cell gives the voltage proper to a Smee, the addition of a small quantity of potassium nitrite to the compartment containing the platinum plate, at once causes the development of the higher voltage characteristic of a nitric acid cell. On removing the nitrous acid thus introduced, by the addition of potassium permanganate, hydrogen peroxide or urea, the voltage drops again to the lower limit. In performing this experiment with potassium permanganate, a voltage still higher than that of an ordinary Grove cell is noticed for a moment, on account of the presence of permanganic acid acting as a depolariser. This, however, is quickly reduced, and the aforesaid drop takes place. On adopting the reverse method of experimenting, and removing nitrous acid (by treatment with urea or potassium permanganate) from nitric acid of a strength (38 per cent. HNO_3) such that it is capable of acting as a depolariser, the voltage proper to a Grove cell is diminished to that characteristic of a Smee, in spite of the fact that the acid is of adequate strength to act in its customary manner under normal conditions. It appears, therefore, that nitrous acid, rather than nitric acid, is the true depolariser in a Grove cell, or, to be more precise, that nitric acid is capable of oxidising the hydrogen which would otherwise be liberated at the platinum plate only in the presence of nitrous acid. The function of the nitrous acid is precisely similar to that which it assumes in the action of nitric acid on metals, the presence of the former being frequently essential for the activity of the latter.

ELECTRIC FURNACES AND THEIR APPLICATION TO THE TRANSFORMATION OF CARBON INTO GRAPHITE.*

BY CH. STREET.

Gentlemen, the honour of reading this Paper belonged of right to my colleague M. Charles Girard, and I have to thank him for having allowed me to give you an account of our labours.

Before describing our methods of transforming carbon into graphite, methods which are founded upon the employment of special electric furnaces, we thought it would be a good thing to review for your benefit the interesting attempts that have been made in the direction of applying electricity to metallurgy, by making use of the extremely high temperatures placed at our disposal by the electric current. We thought it appropriate for the Société Internationale des Electriciens to record the results obtained, in order that it might assist progress towards the distant goal which we shall certainly reach in the future. The limited scope of this communication and the fear of tiring you by a too detailed *exposé* obliged me to limit the number of inventions to which I shall call your attention.

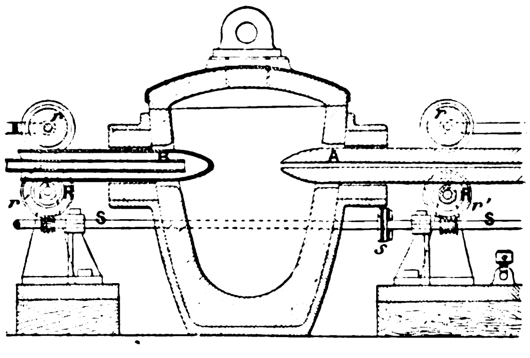


FIG. 1.—Siemens Furnace exhibited at the International Electrical Exhibition of 1881.

Apparatus in which heat is produced by means of electricity may be divided, like electric lighting apparatus, into two large classes; some furnaces are based on the incandescence of a resisting portion of the circuit, the others on the use of the electric arc. The latter are those which enable us to obtain the most powerful effects and which it would seem are destined to yield the most valuable results.

The International Electrical Exhibition of 1881 acquainted us with the two first electric furnaces which may be regarded as the starting point of all apparatus of the kind. The apparatus exhibited by Messrs. Siemens consisted of a carbon crucible heated by an electric arc in the interior (*see* Fig. 1). The carbon crucible containing the substance to be heated had two apertures through which the electrodes passed. A carbon lid enclosed the contents. The electrodes were either both of carbon or the positive was of carbon and the negative was of metal and kept cool by circulating water. The electrodes were fed forward automatically as they were consumed by means of a device which I will not stop to describe. The Siemens electric furnace could be arranged in another way when the material in the crucible was a good conductor of electricity. The current was brought to the bottom of the crucible by a platinum screw *a* (Fig. 2) and transmitted to the conducting substance A, which was thus placed in connection with the positive pole. An arc was established between A and the negative pole B, which was cooled by circulating water.

The second piece of apparatus to which I will allude is that of our colleague M. Louis Clerc. This consisted of a block of magnesia or carbonate of lime (Fig. 3), in which a cavity was hollowed out where the arc played. The electrodes consisted of two 20mm. carbons. In this furnace its inventor volatilised silica and lime. If my memory serves me aright M. Clerc, who publicly

* Paper read before the Société Internationale des Electriciens.

Digitized by Google

repeated his experiments every evening before the visitors to the Exhibition, sent M. Daubrée some very curious specimens of crystalline lime, products of the condensation of the substances volatised in his furnace.

In 1885 Messrs. Eugene and Alfred Cowles took out a patent for an electric furnace which was the starting point of their interesting work on the production of aluminium. In this furnace the heat was produced by bringing the material to be treated to incandescence by means of the electric current, the charge being

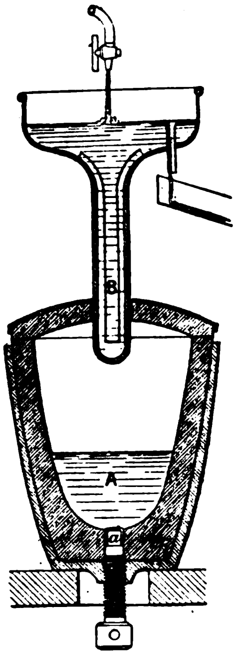

FIG. 2.—Siemens Furnace: Another form.

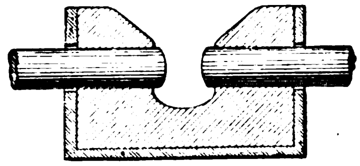

FIG. 3.—Clerc Furnace.

previously pulverised and mixed with powdered retort carbon (Fig. 4). The first apparatus which was made was intended for the reduction of zinc ores, and its use was extended to the reduction and fusion of other ores, especially aluminium, silicium, magnesium, and boron ores. This furnace consisted of a cylinder A, made of silica or any other non-conductor of electricity. This cylinder was surrounded with powdered charcoal B, or any other bad conductor of heat. One end of the retort was closed by a plate of carbon

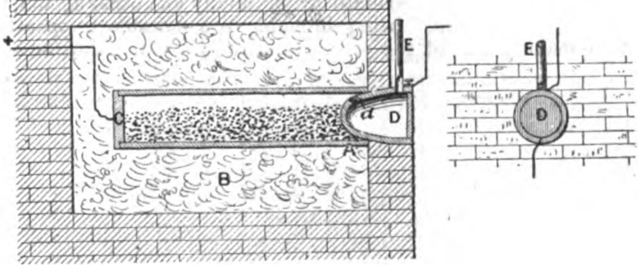

FIG. 4.—Cowles Furnace (1885).

C, which formed the positive electrode. The other end was closed by a graphite crucible D, which formed the negative electrode. This crucible, at the same time as it served as a negative electrode, formed a gas-tight plug for the retort and a condenser for the zinc vapour. The charge, a mixture of ore and carbon, was introduced through the aperture closed by the crucible.

In 1886 Messrs. Cowles patented a furnace (Fig. 5) in which the material to be treated was packed around two carbon electrodes, in close proximity at first, but gradually separated as the electric resistance of the furnace fell. At the start the electrodes were 25mm. apart; at the end of the operation they were 1·2 metres apart. This pattern of furnace shows considerable similarity to that which later on was made use of by Mr. Acheson for the production of carborundum, with the difference that the carbons in the latter furnace were maintained permanently in contact. The difficulties encountered by Messrs. Cowles in following the progress of the process going on inside their furnace, and estimating the separation to give to their electrodes, led them in the same year (1886) to take out a patent in which they claimed the simultaneous use of an ammeter and a resistance interposed in the circuit of an electric furnace with a view to the control of the process (Fig. 6).

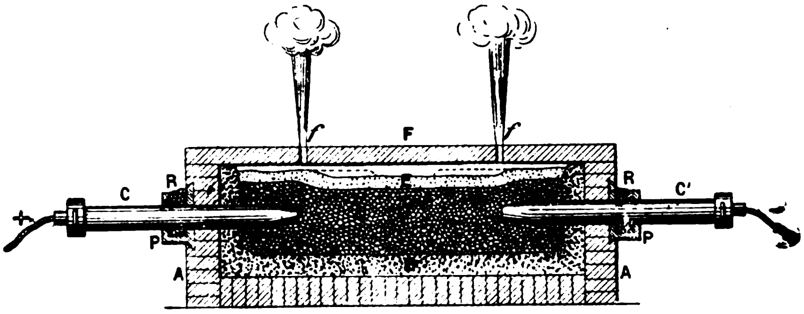

FIG. 5.—Cowles Furnace (1886).

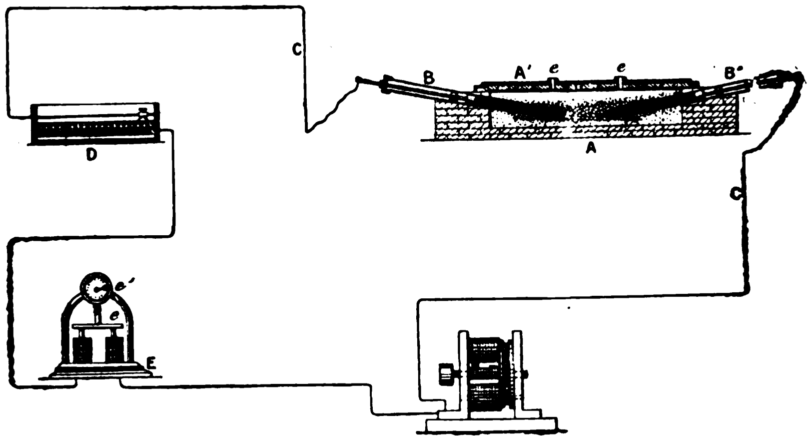

FIG. 6.—Cowles Patent 2403 of 1886.

In 1886 Messrs. Rogerson-Statter and Stevenson took out a patent, the object of which was the utilisation of electromagnetic attraction and repulsion to control the path of the electric arc when employed to produce the heat of a furnace. There is often an advantage in keeping the arc in a fixed position, either at a distance from or close to the material to be heated. In this patent the desired attraction or repulsion was produced by means of a permanent magnet, an electromagnet, or a solenoid. One of the arrangements employed is shown is Fig. 7. A is the body of the furnace, B and C are the two electrodes. On either side of the furnace are the two poles D of the electro-magnet. The polar

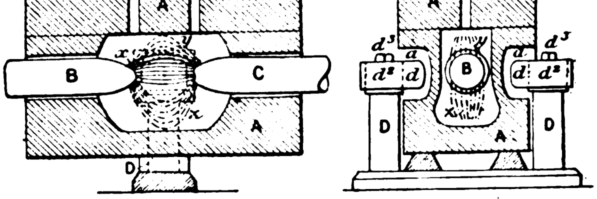

FIG. 7.—Rogerson-Statter and Stevenson Electromagnetic Device for Deflecting the Arc (1886).

expansions are movable in order to permit of the air-gap being varied. The effect of the electro-magnet is to deflect the arc towards the top or bottom of the furnace, according to the direction of the current circulating around the electro-magnet coils.

In 1887, MM. Bernard Frères patented the furnace shown in Fig. 8. Inside the furnace there was a carbon crucible, C, containing the substance to be treated. This crucible was inside a second crucible, C′, made of refractory material, and resting on a carbon support, p, connected to the positive pole of the source of electricity. The carbon electrode a was connected to the negative

Digitized by Google

pole. The crucibles C and C′ were first heated by fuel burnt on the bars G, and when the charge had attained a suitable temperature the heating was completed by an electric current, which at the same time electrolysed the substance contained in the crucible.

In 1887, M. Héroult patented a furnace intended for the production of aluminium. The crucible *a* (Fig. 9) contained the bath of cryolite (double fluoride of aluminium and sodium). This crucible was placed in a second crucible, *b*, made of graphite or plumbago, and resting on stand *c*, which was interposed between it and the fire bars. The electrodes *e* and *e′* were of carbon. The anode was

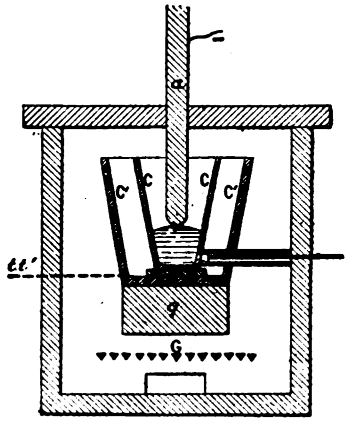

Fig. 8.—Bernard Compound Furnace (1887).

placed in the axis of the crucible, and the cathode was formed by the crucible itself, which was closed by the lid *g*.

In 1887, Messrs. Cowles took out a patent, the subject of which was an electric furnace in which the charge was introduced in a continuous manner. The positive electrode A (Fig. 10) is formed by a carbon tube. B is a feed-hopper, having its lower end fixed to the top of the electrode A. C is the negative tubular carbon electrode, fixed to the plate D arranged at the bottom of the furnace. The containing walls E are of refractory and silica bricks. A packing F of charcoal, or of lime and retort carbon mixed, surrounds the negative electrode C, and insulates it electrically and

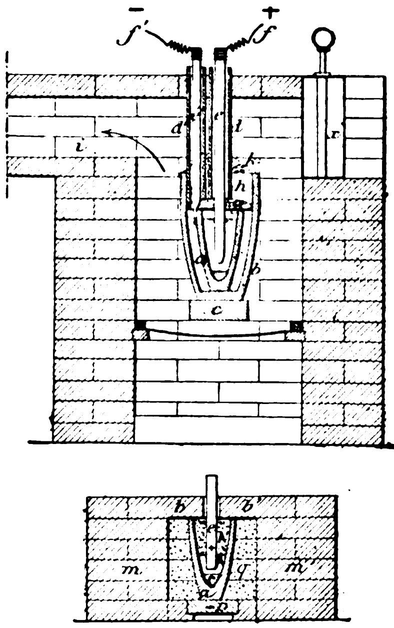

Fig. 9.—Héroult Furnace.

thermally. A packing, G, similar to the above, surrounds the zone of fusion between the two electrodes. The grain of this packing is, however, coarser, in order to allow the gases which result from the reactions of furnace to escape by the tube T which leads them to the condenser *t*. The upper part of the furnace is closed by the plate H, provided with an aperture *h*, through which the positive electrode slides freely. An arm, I, pivoted at *i*, enables the electrode A to be raised or lowered by means of a screw, in order to increase or diminish the zone of fusion or compensate for the consumption of the electrodes.

In 1888 Mr. Readman took out a patent for a furnace (Fig. 11) intended for the production of phosphorus. The furnace A consisted of refractory material, the heating chamber receiving two electrodes, K, which brought an arc to bear either above or in the vicinity of the material from which the phosphorus was to be extracted. In 1888 M. Reuleaux took out a patent for an electric cupola. This consisted of a piece of circular masonry (Fig. 12),

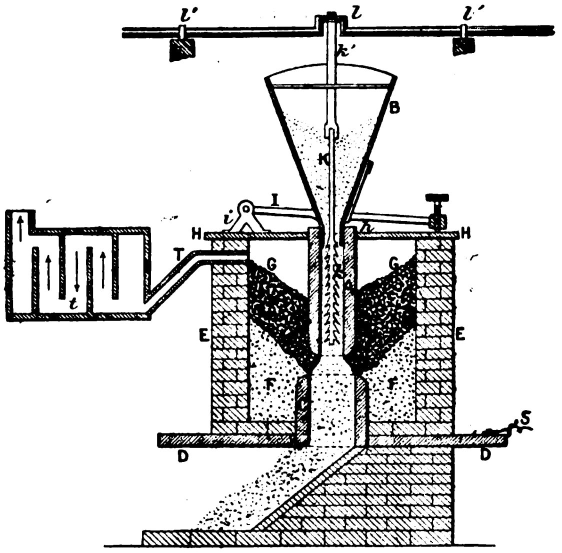

Fig. 10.—Cowles Continuous-Feed Furnace (1887).

divided at the upper end into three compartments, F F′ F″. These three compartments terminated in a common heating chamber, in which were a series of electrodes, E E′. Tubes C and T allowed of the material being heated before it reached the region of the arc. In 1888 Mr. Crompton patented a mixed furnace (Fig. 13),

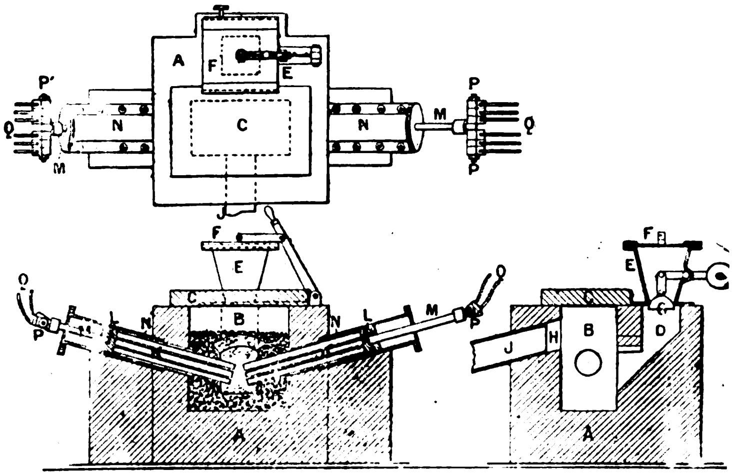

Fig. 11.—Readman Furnace for Phosphorus Reduction (1888).

in which the heat was produced by electrictiy and other agents, the material to be treated being brought to a suitable temperature before making use of the electric current; *a a* are the burners,

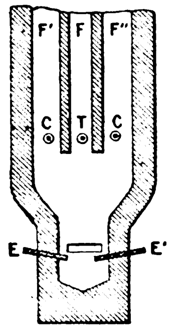

Fig. 12.—Reuleaux Cupola.

through which the combustible gases were introduced into the interior of the furnace; D and D′ are the electrodes, consisting of a bundle of carbons secured in a holder. In 1889 M. Kiliani patented a device whereby an oscillatory or circular motion was

Digitized by Google

given to the anode with a view to avoid the formation of solid crusts at the surface of the molten bath, crusts which prevent the

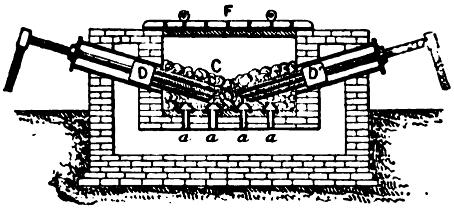

FIG. 13.—Crompton Compound Furnace.

introduction of fresh matter into the furnace (Fig. 14). In 1889 Mr. Thomas Parker devised the furnace depicted in Fig. 15, in

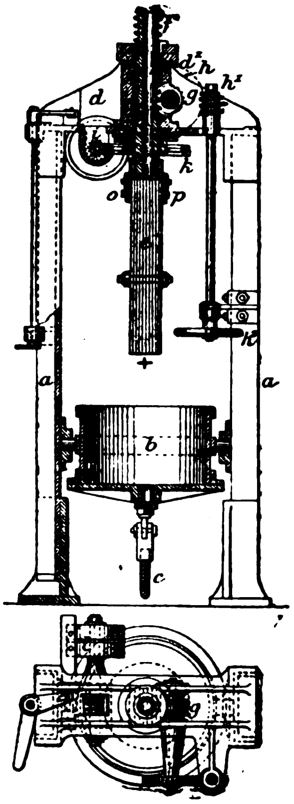

FIG. 14.—Kiliani Furnace with Oscillating Anode (1889).

which the heating was due to two rows of electrodes placed opposite each other. At the commencement the electrodes are brought

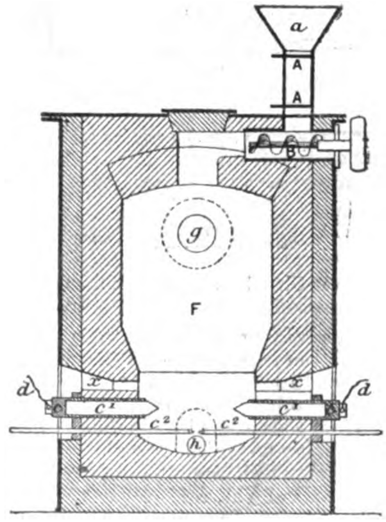

FIG. 15.—Parker Furnace.

into contact, and the charge is then introduced. The electrodes are next separated and afterwards brought together as fast as they burn away.

In 1890 Mr. Willson patented a device, the object of which was to reduce the consumption of the anode in mixed electric furnaces; that is to say, in furnaces which are calorific as well as electrolytic.

To this end the anode (Fig. 16) was a tube of carbon through which hydrogen, illuminating gas, or some other hydrocarbon gas was passed. This arrangement was used mainly to make aluminium-bronze by means of copper and corundum.

In 1890 Herrn Schneller and Astfalck patented the aluminium furnace shown in Fig. 17. The necessary heat is obtained by means of high voltage currents supplied by secondary generators. The high voltage is employed to overcome the high resistance of the substances to be reduced, and also to take advantage of having

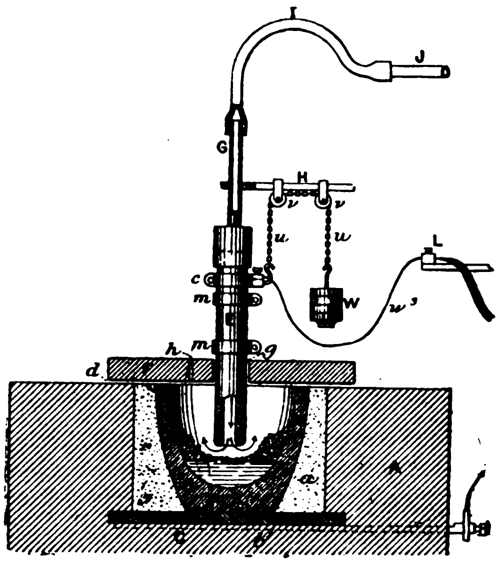

FIG. 16.—Willson Furnace with Tubular Carbon Electrode, through which hydrogen or a hydrocarbon gas is passed (1890).

a large surface presented to the gases which are to effect the reduction. This reduction is effected by hydrogen or a suitable hydrocarbon introduced into the interior of the furnace. The charge consists either of alumina, or of sulphide, chloride, or fluoride of aluminium. The fall of potential across the furnace terminals is some 20,000 volts.

In 1892 M. de Laval patented a furnace for the fusion of metals. The method employed consists in producing the heat necessary to effect the fusion by passing the current through a layer of molten matter of low conductivity, which is by that fact brought to a very high temperature. The current employed is alternating, to avoid electrolytic phenomena. Two arrangements are used, according as

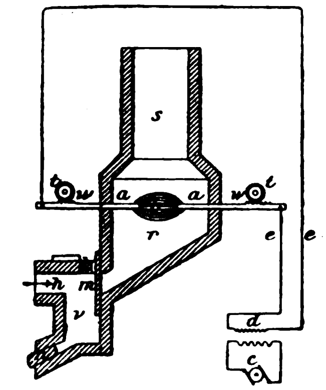

FIG. 17.—Schneller-Astfalck High Voltage Furnace (1890).

the metal is more dense or less dense than the electrolyte. Fig. 18 shows the apparatus used in the former case. The interior of the furnace is divided throughout its length into two parts by a bridge, C, of refractory material. The electrodes D and E are at the bottom of the furnace, and the circuit is completed by passing over the ridge C through the electrolyte. The metal to be melted is introduced through the opening B, and flows out through the pipes F and G. The excess of electrolyte gets away by the overflow pipe H.

On May 25, 1893, my colleague, M. Girard, and I took out a patent, the subject of which is a continuous electric furnace, which enables us to heat or treat any kind of material by electricity

Digitized by Google

by causing it to circulate or pass in a continuous manner through the furnace. I lay stress from the beginning on the essential feature, which lies in passing the substance to be treated through the furnace. In the electric furnace the high temperatures are extremely local, and when substances are put into the furnace in the ordinary way they are heated in a very irregular manner, particularly when we have to deal with moderately good conductors of heat. To overcome this, we may increase the number of electric "burners," but by this means we reach a current consumption quite out of proportion to the result obtained. On the other hand, the circulation of the material through the furnaces permits of the establishment of continuously producing furnaces. Fig. 19 shows, partly in section, partly in elevation, a furnace applicable to the heating of solid materials in the shape of rods, bars, or wires. The apparatus consists of a block of refractory material *a* in one or more parts

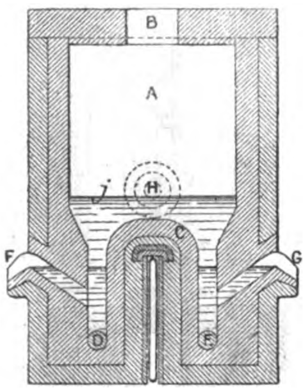

Fig. 18.—De Laval Furnace (1892).

secured by an external metal frame *b*. In the centre of the block there is a metal cavity *c*, which is, properly speaking, the heating chamber. In this cavity there is an orifice, by which the carbon *d* penetrates into it, and a tunnel traversing the walls of the furnace from one end to the other and into which the bar *e*, which is to be treated, is introduced. This bar *e* is given a motion of translation which should take it through the furnace and the heating chamber at a rate depending on its mass, and the temperature to which it is desired to raise it. The actual heating chamber is composed of a block of carbon in one or more pieces according to the size of the apparatus. In the model shown in the illustration the circuit is between the piece *e* to be heated and the carbon *d*. The arc is struck between the two electrodes, keeps itself in a fixed position, notwithstanding the motion of *e*, and successively springs from

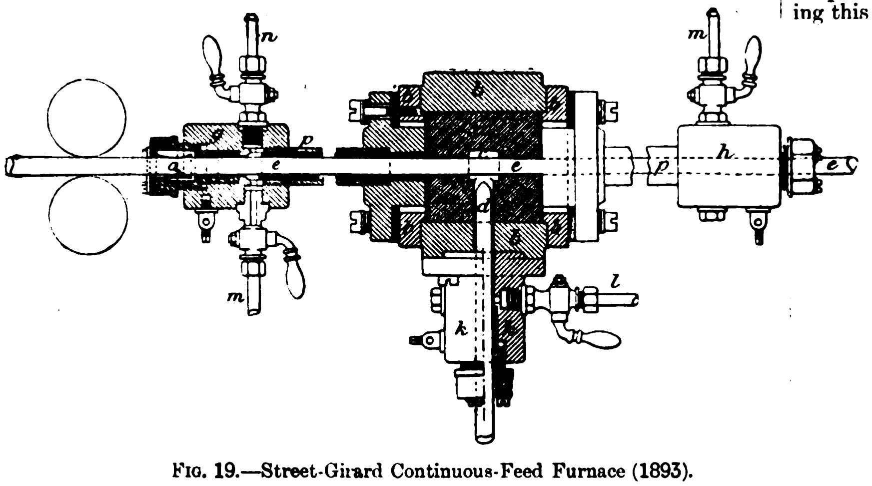

Fig. 19.—Street-Girard Continuous-Feed Furnace (1893).

every point along a generatrix of the piece to be heated, raising these points to a very high temperature. It is easy to see that the speed with which the piece moves determines the average temperature of each element. When the heating is required to take place in any particular gas the piece *e* passes through stuffing boxes *g* and *h*, and the carbon *d* through the stuffing box *k*. The gases enter and leave at *l* and *m*, and at *n* a manometer is fixed. The current is brought to *e* by a rubbing contact at *o*. The length of the arc between the carbon *d* and the piece *e* can be kept constant by means of one of the arrangements usually employed in arc lamps. The piece *e* traverses, before entering and after leaving the furnace, propersuitable tubes *p*, in which it is prepared on the one hand for the action of the furnace by passage through the special gas therein contained, and on the other cooled before passing through the stuffing-box by which it leaves. The working of the apparatus is absolutely continuous, since a constant succession of bars or rods may be passed through it. In the figure the object to be heated is shown undergoing the action of a single arc, but generally the object to be heated serves as a common electrode to two arcs in succession. The movement of translation is given to the piece of work by means of rollers actuated by an electric motor.

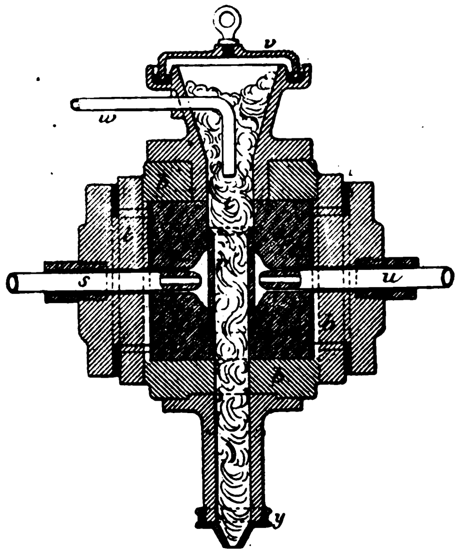

Fig. 20.—Street-Girard Furnace with Fixed Tubular Recipient.

When it is desired to pass pulverulent material capable or not of being fused, the piece *e* may consist of a tube, closed at either end and containing the material to be treated. The cylinder moves across the furnace in the manner already described, and is made of some material capable of withstanding the temperature it is called upon to resist. Instead of circulating with its recipient or crucible the substance to be treated may instead be set in motion inside the containing vessel, which may then be kept fixed. In this case we employ the arrangement shown in Fig. 20, where the heating chamber consists of a carbon tube *r*, which is at the same time a crucible and an electrode for the arc. The heat is then obtained from two arcs in series or from several groups of arcs two in series. When the material, after its passage through the heating chamber or crucible *r*, is capable of fusion, the pattern shown in Fig. 21 is adopted, in which there is an outlet *z* so arranged that, notwithstanding this orifice, the special gases can be kept in the furnace.

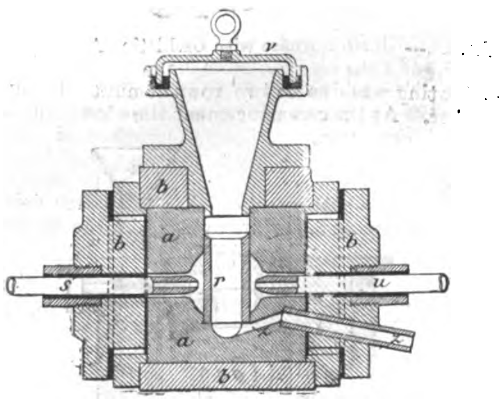

Fig. 21.—Street-Girard Furnace for Molten Substances.

It is sometimes an advantage to spread the action of the electric arc more evenly over the material to be treated. To attain this end we cause the arc to rotate within the furnace by bringing a suitable magnetic field to bear upon it. Let us take, for instance, the treatment of bars, rods and wires just described. The rod or bar *e* (Fig. 22) undergoing treatment passes through a succession of carbons *s*, the ends of which are pierced, as shown, with holes concentric with the axis of the rod or bar *e*. The arc is struck between *e* and the carbons *s* at a certain point by drawing the carbons through their stuffing boxes until they come into contact with *e*. Upon this element of current we bring a perpendicular magnetic field to bear by winding the outside of the furnace with coils traversed by an electric current, the metal cover *b* being in this case of non-magnetic material. Under the influence of this

Digitized by Google

field the arc rotates in a plane at right angles to the bar *e*, and thus touches it at every point on its circumference. The speed of rotation of the arc is a function of the magnetic field in which it is placed and the strength of the current passing through the arc. The principle of the rotating arc is applicable to the different patterns of furnace we have devised. The combination of the rotary movement of the arc with the translatory movement of the bar to be heated results in the arc touching every point of the surface of the piece, and there is consequently a perfectly symmetrical distribution of heat.

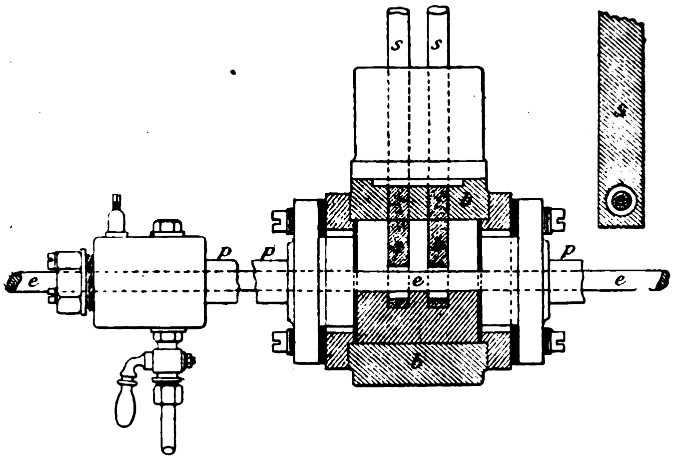

FIG. 22.—Street-Girard Furnace with Rotating Arc.

On August 1, 1893, M. Chaplet took out a patent for an electric furnace based on the researches of M. Moissan. These furnaces (Figs. 23 and 24) are those with which M. Moissan carried out those interesting investigations with which he has entertained the scientific world. I will not stop to describe the apparatus, which is well known to all.

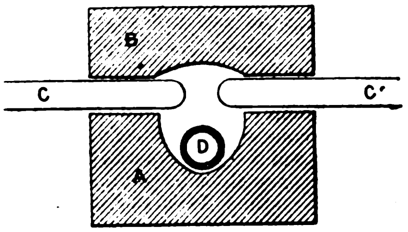

FIG. 23.—Chaplet-Moissan Furnace (1893).

Continuing our researches on the rotating arc we devised, in 1894, a type of crucible based on this principle. In this piece of apparatus the arc is influenced by a suitable magnetic field, and rotates more or less rapidly around the surface of the crucible and of the electrode. By this means we have succeeded in making the maximum use of the heat generated, and in effecting a uniform distribution of the heat so generated; this latter point is of considerable importance so far as the duration of the crucibles is concerned.

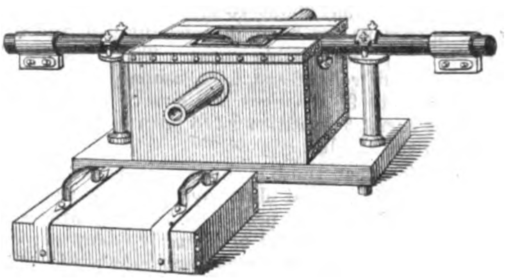

FIG. 24.—Chaplet-Moissan Furnace (1893).

The arc can be made to rotate either around the external or internal surface of the crucible, or around two independent electrodes, between which the crucible is situated.

In Fig. 25 is shown an arrangement which allows us to heat a crucible by an externally-rotating arc, the arc revolving round the axis of the crucible in a horizontal plane. *v* is the carbon crucible, supported at the centre of the furnace by its rim, which rests on a ledge cut in the carbon block *a*, which is itself placed within another block of refractory material *g* of silica, magnesia, or some other suitable substance, this block in its turn resting on a slab of refractory material *f*, a similar slab *h* resting on the top of *a* and *g*. Finally, two blocks of carbon, *c* and *b*, complete the interior of the furnace. All these parts are contained within a metal tube, closed top and bottom by the covers *j* and *j'* by the intermediary of an insulating joint. The blocks *c* and *f* are pierced by a channel through which the carbon electrode *e* is passed, the shape of the electrode being such that it envelops the lower end of the crucible without touching it. The crucible *v* is kept pressed down on its seat *a* by means of a carbon plug *d* carried in the holder *l*, the latter being contained in the tube *k*, together with the spring *r* and the abutment ring *q*.

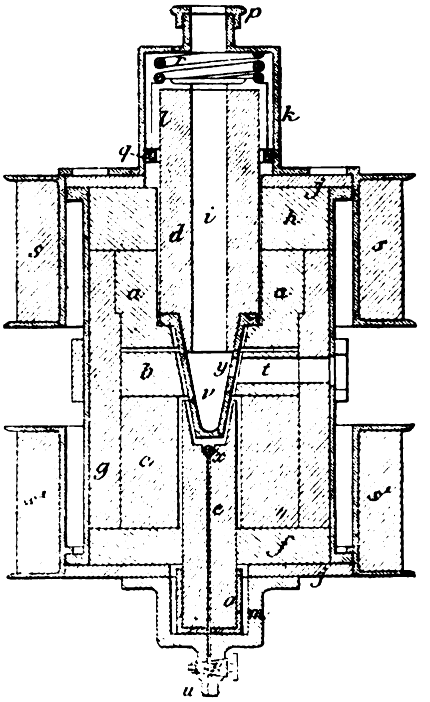

FIG. 25.—Street-Girard Furnace with Rotating Arc (1894).

The tube *k* is mounted on the upper cover *j'* by a bayonet joint, and is stopped at the top by a screw plug *p*, which tightly secures a sheet of mica. The carbon stopper *d* may be pierced at the centre by a hole *i*, through this hole and the mica the reactions going on may be followed. In attaching *k* to the top plate *j'* the stopper *d* presses upon the crucible *v* with a pressure proportional to the strength of the spring *r*. If the top and bottom plates *j'* and *j* are connected to the two poles of the source of electricity, an arc will start between the crucible *v* and the carbon *e*. To cause this arc to revolve round the outside of the crucible we place outside the metal frame two solenoids, *s* and *s'*, traversed by an electric current which obliges the arc to rotate in a plane perpendicular to the axis of the crucible and around the axis of the crucible as its axis of rotation. The crucible *v* is pierced at a certain height by a hole *y*, which is opposite a tunnel *t*, which is run through the blocks *b* and *g* and the metal frame. When the material introduced into the furnace *v* is capable of being fused by the high temperature attainable in it, the whole system is tilted round an horizontal axis, and the molten material flows away and is collected without interrupting the work of the furnace.

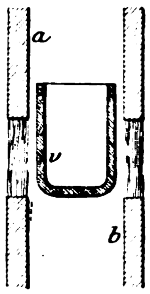

FIG. 26.—Street-Girard Furnace. Crucible between ends of two tubes.

In Fig. 26 is shown an arrangement by which a crucible *v* placed inside two tubes *a* and *b* is heated. The arc is stuck between the ends of the two tubes, and runs round under the action of a two-

Digitized by Google

phase current. A crucible of this type has enabled us to effect in a few minutes the fusion of a 25 gramme nugget of platinum, and to reduce the oxides of manganese, uranium, and vanadium and also tungstic acid. The current employed was 80 amperes at 110 volts.

When the crucible is connected to the negative pole the metals obtained are highly carburised, and when the crucible is connected to the positive pole one obtains, if the operation is carried out with certain precautions, metals containing only a trace of carbon.

The electric furnaces devised by us have been made chiefly with a view to raising artificial carbons, such as they are now made, to an extremely high temperature. One of the most important factors in this process is the baking of the raw materials. The higher the temperature to which they are raised the more valuable do they become; their conductivity and general qualities increase with this temperature, and are a function of the point to which the baking was carried. Fom the experiments we had made in this direction we foresaw that by raising the carbons to the highest temperature available we should obtain new and interesting results. To realise this programme we thought that the best way, and the one that would be the most efficient, would be that in which the arc was made to play actually on the surface of the carbon to be treated; a method which we were able to make use of by means of our furnace. When two arcs are used in series on either side of a carbon rod or strip to which a translatory motion has been given, the arcs, if the current is relatively small, trace two generatrixes on the carbon, which are graphitic in character. The width of the line traced out by the arc is about 2mm., with a 14mm. carbon and a current of 40 amperes, and the depth of the graphite is about 1·5mm. In proportion as the internal temperature of the furnace increases the region of change widens and deepens. At the end of a certain time the carbon treated, which presents excrescences and hollows at the spot touched by the arc, still retains its shape absolutely unaltered, though it is entirely transformed into graphite, or rather the extent to which the transformation is carried becomes uniform throughout its mass. From this moment the arc no longer has its customary filiform appearance. When an alternate current is employed the carbon electrodes and the carbon under treatment appear to be the seat of a volatilisation of carbon over their entire surface, as is shown by the appearance of the ends of the electrodes and of the surface of the carbon that has been transformed.

When rotating-arc furnaces are used, then at the beginning of the experiment, and when the rate of translation of the pieces undergoing treatment in the furnace is exaggerated, the pieces exhibit on their surfaces the marks of a helix of graphitic carbon. The pitch of the helix varies for the same current with the speed of the carbon, and with a suitable speed the entire surface becomes graphitic. The wear of the carbons in these furnaces is extremely small.

In the case of rotating arcs the currents used are continuous, the piece undergoing treatment forming the positive pole. This arrangement has the advantage of placing the fixed electrode in the best condition for continuous work without the necessity of any mechanism for adjusting the length of arc.

In the case of furnaces in which the pieces to be treated pass between two fixed electrodes we employ preferably alternate currents. Owing to the small wear of the electrodes it is only necessary to adjust them by hand every hour. This consumption is 5mm. for a 300 ampere current and 40mm. electrodes. When the furnace has settled down to its work it is perfectly regular in its action; the ammeter placed in circuit remains absolutely steady, and the voltmeter across its terminals enables the length of the arc to be regulated with the greatest possible nicety.

Given the same current and rate of translation, the rate of transformation of any carbon into graphite varies with the mixture of which it is made. A carbon made with gas retort coke and tar is not converted into graphite to such an extent as one containing 2 per cent. of silica or 2 per cent. of boric acid. A similar result is obtained with powdered iron mixed with gas retort coke in the same proportion.

The nature of the medium appears to have but little influence on the tendency to transformation. Carbonic oxide, nitrogen, bisulphide of carbon, give similar results. Hydrogen alone would appear to slightly aid the change.

When carbons are subjected to this baking process the foreign matter they contain is volatilised or transformed into carbide, having a very high percentage of carbon and very difficult to attack with acid. The carbons obtained by this process possess very interesting new properties. The electric conductivity is augmented in the ratio of 1 to 4; the thermal conductivity increases in the same ratio. Finally, the resistance to combustion, is considerably increased, as well as the resistance to fused alkali. The density of an ordinary 14mm. carbon was found, before treatment in the electric furnace, to be 1·98, and that of the same carbon after passage through the furnace was 2·6, the proportion of carbon transformed into graphite being 85 per cent. The density of a 25mm. carbon after passage through the furnace was found to be 2·36, the proportion of graphite being 80 per cent. These differences depend upon the strength of the current, the speed at which the carbon is passed through the furnace, and the amount of carbon concerned. The proportion of graphite was determined by analysis by Berthelot's method, the main features of which I may be permitted to sum up. The carbon to be investigated is reduced to an impalpable powder, and then mixed with five to six times its weight of separately pulverised chlorate of potash. The material is then thrown, in small amounts, into fuming nitric acid so as to obtain a sort of paste. After the material has been left for a few hours, it is heated gently in an open vessel at 50°C. or 60°C. for three or four days. The material is then washed in water to eliminate the potash salts. This series of operations is renewed five or six times in order to completely dissolve the amorphous carbon, and to transform the graphite into graphitic acid.

The peculiar properties of these new carbons enable us to employ them with advantage as carbons for arc lamps, as anodes in electrolytic operations, and as dynamo brushes. When used as the positive carbons of arc lamps they wear away half as quickly, other things being equal, as ordinary carbons. Used as anodes these carbons behave in an altogether extraordinary manner, whether for electrolysis by the wet way or by the way of fusion. The ordinary artificial carbons rapidly disintegrate, crumble, and render all industrial use of them impossible, owing to the necessity of having to unmount and remount the electrolysers at extremely short intervals. In the particular case of the electrolysis of the metallic chlorides the results obtained are perfect. Unfortunately we cannot give you many commercial results, the use of our carbons for this purpose being, as yet, in the experimental rather than in the commercial stage. Nevertheless, we can give you some figures which have been given to us by Mr. Greenwood, the inventor of the electrolyser exploited by the Caustic Soda and Chlorine Syndicate of London and intended for the production of caustic soda. Mr. Greenwood's electrolyser is composed of a series of vats arranged in cascade. Each vat is divided into five compartments, each compartment forming a unit electrolyser. Each of these units contains an iron cathode and a carbon anode constructed in a special manner, the electrodes being separated by a porous diaphragm, which is an important feature of the invention. This diaphragm consists of a rectangular frame supporting a series of V-shaped troughs arranged so that the lower point of the V enters into the groove of the one immediately below it. These channels are of glass or slate, and are filled with fine Canadian asbestos. This arrangement enables Mr. Greenwood to obtain a porous diaphragm of low resistance, and to effectually separate the chlorine liberated in the anode compartment from the product of the cathode compartment, since owing to the interlacing of the V-shaped elements of the porous partitions they present a path which it is impossible for the chlorine to take, owing to its density. The anode is constructed in the following manner. A certain number of carbon plates are coppered on one side, then tinned, and then placed side by side in a mould so as to form one large plate. In order to unite the constituents of the plate an alloy of lead and antimony is run into the mould, so that after solidification one obtains a set of carbon plates secured in a skeleton-like metallic frame. This skeleton, and the joints covering the plates, are covered with an insulating cement, unattackable by acids. Moreover, the carbons are dipped in paraffin wax in order to stop up the pores and prevent the electrolyte from getting into contact with the metal at the back. When these anodes are constructed with ordinary artificial carbons they become, after a few days in the vats, quite useless, the carbon crumbling into dust. Mr. Greenwood has fitted a certain number of his electrolysers with electro-graphitic carbons, and that about 15 months ago. From that date until now the apparatus has been in constant use, and the anodes do not exhibit any perceptible wear. The current densities employed have varied from 100 to 1,000 amperes per square metre of anode (9 amperes to 90 amperes per square foot). On several occasions greater current densities have been employed without in any way injuring the anodes.

We are of opinion that these carbons will contribute largely to the development of industrial electrolysis, seeing that they bring within the region of industrial practice numerous processes which up to the present have remained of a purely laboratory character. The high electric conductivity of these electro-graphitic carbons, and their perfectly homogeneous texture, which causes them to resemble cast material, should recommend them to the special attention of electricians with a view to their use as dynamo brushes. Ordinary carbon brushes possess, generally speaking, many advantages, some of which are: suppression of sparking, the possibility of allowing the machine to rotate in either direction without altering the position of the brushes, preservation of the commutator in a good state. The advent of electro-graphitic carbon brushes will permit of the extension of the employment of brushes of this type to machines, which by reason of their construction or conditions of working could not hitherto make use of other than metallic brushes.

Digitized by Google

Moreover, the peculiar character of the carbon of these brushes results in an extremely small coefficient of friction, and they do not unduly foul the commutator; they further enable us to obtain high conductivity at the point of contact between the brushes and the commutator. MM. Sautter-Harlé have found that electro-graphitic brushes can stand a current twice as great, other things being equal, as that which has been found dangerous for ordinary carbon brushes.

We are endeavouring at the present moment to adapt our electrical furnace to the making of incandescent lamp filaments, and we shall hasten to inform you of the results obtained in this direction.

In concluding this communication, I have to thank, in the names of M. Girard and myself, Mr. Frederick Maquaire, who has superintended the construction of the various type of furnaces, and M. André Tonnard, head of the laboratory of the Société le Carbone, who has superintended with the greatest possible devotion experiments often delicate and sometimes dangerous.

THE NEW WESTINGHOUSE WORKS AT EAST PITTSBURG.—III.*

New Types of Apparatus.

Generators.—For polyphase work the Westinghouse Company is building two distinct types of generators, which are distinguished by their form of armature winding. The older style, known as the "plus two" type, and used only for two-phase work, has a toothed armature with two more teeth on the core than there are poles in the field. The newer type of machine is available for the generation of either two-phase or three-phase currents, and has what is called a "distributed" winding; that is, the coils are laid in slots in the armature, and the winding is made continuous. This is the type of machine installed in the Westinghouse power plant. The distributed form of winding, shown in Fig. 1, gives a very effective E.M.F. wave, and avoids fluctuations in pole-face inductions, which are often the accompaniment of the toothed armature. The standard line of machines is designed to be belt-driven, but may be modified to suit direct connection when desired.

The following is a list of generators which at present are being regularly built:—

Two-Phase Generators.

3,600 periods, 1,000 or 2,000 volts.

Rating.—K.W.	Weight.—Lbs.	No. of Poles.	Speed.—R. P. M.
45	3,500	8	900
60	4,500	8	900
75	6,000	10	720
150	12,000	12	600
225	19,000	16	450
300	25,500	18	400

Polyphase Motors.—Fig. 2 shows very clearly one of the latest type of Westinghouse polyphase motors. As will be noticed, there

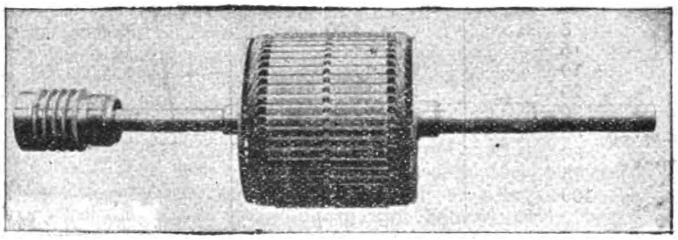

Fig. 1.—Two-phase Generator Armature with distributed winding.

is no external controller or rheostat. The revolving primary is wound very much the same as a direct-current armature, and is supplied with two-phase currents through three collecting rings, the four leads to the winding being taken off inside the rings. The stationary secondary is built up of laminated ring punchings held in position by a circular cast-iron yoke. Instead of distinct pole-pieces and exciting coils, the winding of the secondary element is "distributed," as it is thought that this type of field gives much better results than any other that can be used in a polyphase motor. The windings are connected together through small resistances which are short-circuited after the motor has got under way by throwing the handle of the short-circuiting switch projecting

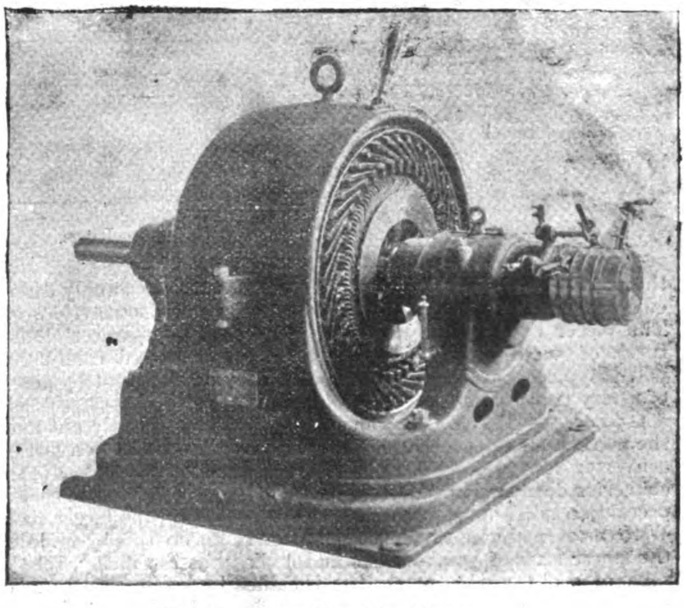

Fig. 2.—40-h.p. Two-phase Motor.

from the top of the yoke. The resistance is necessary in order to insure the large starting torque usually required, and to cut down to a minimum the starting current. Some motors of smaller size which do not require a starting resistance are built with a stationary primary and revolving secondary. In the motor illustrated in Fig. 3 there are no collecting rings on the shaft, the revolving secondary windings being short-circuited on themselves. The current is introduced through stationary windings to the stationary

* Abstract from the *Electrical World* of New York, to whom we are indebted for the blocks illustrating our abstract. Article I. appeared in our issue of July 5th, and Article II. in our issue of August 16th.

D

primary. As these motors have no resistances in the secondary windings to be cut out of circuit after starting they are not equipped with any short-circuiting device.

The following is a list of the standard machines at present manufactured by the Westinghouse Company :—

Two-phase Motors.

1,500 periods. 200 or 400 volts.

Rating.—Brake H.P.	Weight.—Lbs.	Speed.—R. P. M.
3	600	750
5	800	750
10	1,000	750
20	1,500	750
25	2,000	750
30	2,500	750
40	4,000	750

Two-phase Motors.

3,600 periods. 200 or 400 volts.

Rating.—Brake H.P.	Weight.—Lbs.	Speed.—R. P. M.
3	600	1,800
5	800	1,200
10	1,000	1,200
20	1,500	1,200
30	2,000	1,200
40	2,500	1,200
50	4,000	900
75	6,000	900
100	8,000	720

Rotary Transformers.—These machines (*see* Figs. 4 and 5) are built like multipolar direct-current machines, except that they have collecting rings on the other end of the armature. A number of

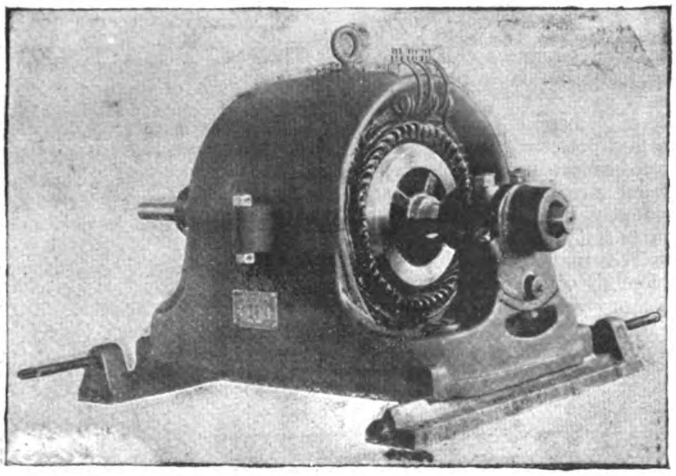

Fig. 3.—5-h.p. Two-phase Motor without Collecting Rings.

these machines are being installed at Niagara to supply direct-current, such as required for field excitation and electrolytic work. The power used by the Pittsburg Reduction Company, manufacturers of aluminium, at Niagara Falls, is transformed from 2,000-volt polyphase currents into low potential direct-current by means of rotary transformers.

Converters.—The Westinghouse Company has recently put upon the market a new type of converter. It is a well-known fact in converter design, that the ratio of radiating surface to the loss in the converter decreases rapidly as the size is increased, so that special precaution must be taken against undue heating in the larger sizes. With most manufacturers it is customary to do this by building the larger sizes of great weight and bulk, thus sacrificing, for the sake of cool running, much that is gained by an increased size of unit. A method for overcoming this difficulty has been devised by the Westinghouse Company. It consists in increasing the radiating surface of the converter, by spreading the coils, outside the iron, at the ends of the converter. The coils of a converter are shown in Fig. 6, and the spread of the coils is easily seen. Greater radiating surface, however, was not the only consideration which led to an increase in the number of coils, for other distinct advantages, both electrical and mechanical, are gained by this subdivision. Electrically, the chief feature consists in the fact that the magnetic leakage is so reduced that the inductive drop, which might otherwise be enormous, becomes practically negligible. The mechanical advantages are that the voltage on each coil is reduced in proportion to the number of coils, making it correspondingly easier to insulate each coil from the others; and the shape of the coils is such that the voltage between adjacent layers is reduced to a minimum, reducing in like proportion the chances or a short-circuit within a coil. All converters of the standard line are provided with a combination block, so arranged that any converter may be

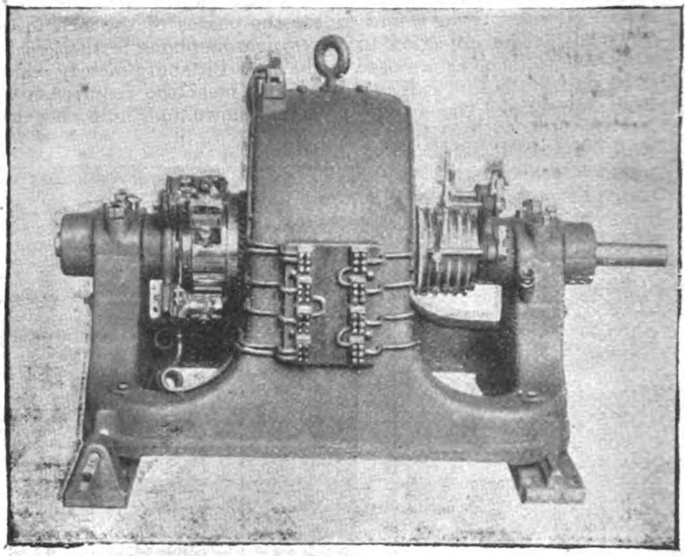

Fig. 4.—10-h.p. Rotary Transformer.

connected for a primary voltage of either 1,000 or 2,000, and for a secondary voltage of either 50 or 100. Fig. 7 illustrates a 100-kilowatt converter built for the Cataract Construction Company at Niagara Falls. The converter is designed to run in oil and is kept cool by the circulation of water through a coiled pipe immersed in the oil. By regulating the flow of water the temperature may be kept down to almost any desired value.

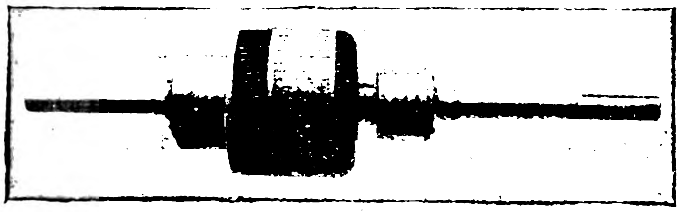

Fig. 5.—Rotary Transformer Armature.

Shallenberger Wattmeter.—The new Shallenberger alternating-current measuring instruments were described in *The Electrician* of January 25th, when the patents were first issued. Since that time a number of instruments have been built for the Niagara installation, and some slight modifications and improvements have been introduced.

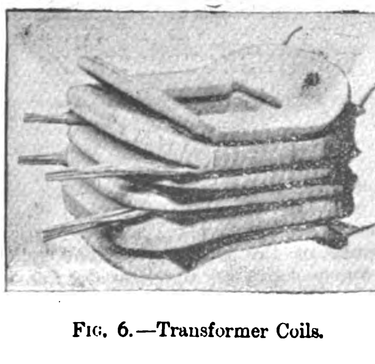

Fig. 6.—Transformer Coils.

Synchronoscope.—When throwing alternating-current machines into parallel it is necessary that the maxima and minima of the E.M.F. waves of the different machines shall be in unison, otherwise the difference of potential will result in an abnormal rush of current and consequent liability to injury to the machines or the

Digitized by Google

windings. For the purpose of determining whether the generators are in multiple, before closing the switch which throws the machines together it has been customary to use incandescent lamps. The objection to lamps has been that the carbon remains incandescent for a short time after the flow of current has ceased, and thus, if the operator waits until the lamps are extinguished, he throws the switch a little too late for perfectly synchronising the machines. In order to know the exact instant at which the generators should be thrown in parallel, the Westinghouse Company some time ago brought out a synchronophone or phase indicator, an instrument which gives a buzzing sound unless the phases of the machine are the same. The objection to the synchronophone is that, on low alternations, such as are used at the East Pittsburg factory and the Niagara installation, it is inaudible. To meet the requirements of low alternations the synchronoscope, shown in Fig. 8, has been developed. It consists of a high resistance coil about a laminated horseshoe magnet, between the poles of which is a small Z-shaped piece of iron normally held by a spring in such a position as to be least effectively magnetised. When there is no current flowing between the machines the needle stands at zero; when there is a difference in phase between the alternators the difference in E.M.F. causes a slight flow of current around the magnet, which deflects the needle. When two machines are connected in multiple through the synchronoscope, the needle will vibrate back and forth, having a periodicity of greater and greater duration, as the machines come more nearly in step. By watching the swinging of the needle the switch may be closed and the machines thus thrown in multiple when the needle is exactly at zero, thereby avoiding even the slightest disturbance of the ammeters. The synchronoscope is designed for use on the secondary of a transformer.

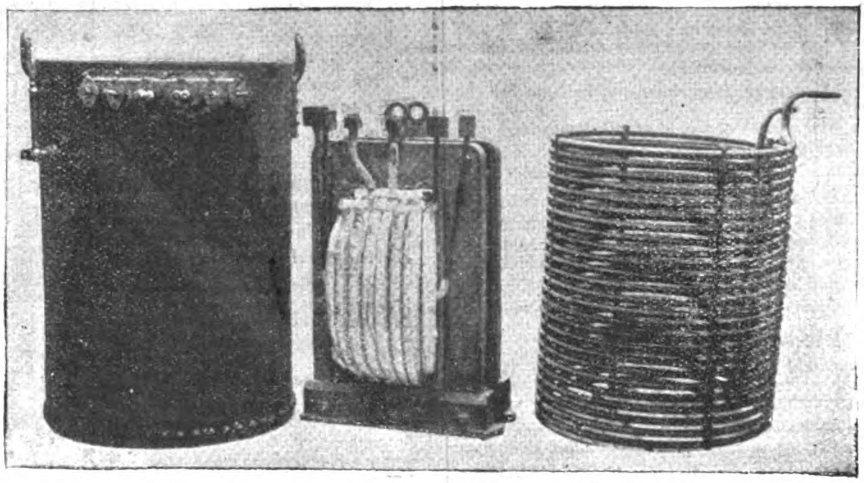

FIG. 7.—100-K.W. Oil Transformer (Niagara).

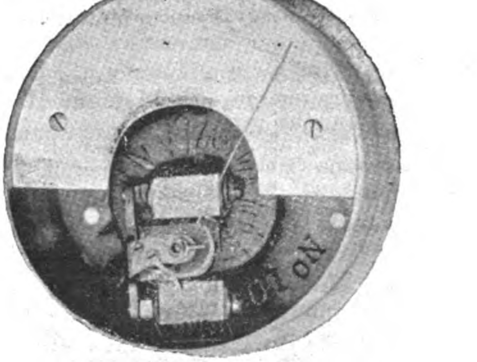

FIG. 8.—Synchronoscope.

New Railway Motor.—A new single reduction series motor of 50 H.P. has just been brought out by the Westinghouse Company to meet the requirements of greater speed or heavier work. It is the same motor that is being used by the Pennsylvania Railroad at Mount Holly, N.J., in its experiments with high-speed electric cars. The novel features are the use of a cast-steel yoke with laminated pole-pieces and a ventilated armature. The motor is entirely encased, and thus made water and dust-proof. It is intended to be used with any one of three sets of gears having a ratio of 1 to 4·86, 1 to 3·44 and 1 to 2·3, and intended respectively for slow-speed freight and snow-sweeper work, city passenger traffic or suburban high-speed service. The very symmetrical and simple form of ventilated armature winding is clearly shown in Fig. 9. The use of air passages parallel to the shaft, in the core, results in an efficient and at the same time very cool running armature. The motor is designed to be suspended by a single spring under the "nose" or lug projecting from the circular yoke, or, as the Westinghouse people prefer, by bars which pass through supports on each side of the motor and have their ends supported on springs.

Economy Coils.—Recent improvements in the construction and regulation of constant-potential arc lamps have wrought considerable change in the methods of arc lighting. The advantages gained in an arc lamp which may be operated from either lighting or power circuits, which may be turned off and on independently of other lamps, and which operates at low potential, make clearly apparent the reasons for the popularity and widespread use of constant and potential arc lamps. On direct-current constant-potential circuits, arc lamps are usually operated in a series of two or more in connection with a small resistance. On alternating-current circuits it is customary to operate each arc lamp independently, by the use of some type of transformer. This method insures complete and unrestricted control of every individual lamp. The Westinghouse Company has brought out what they call an "economy coil" to take the place of the comparatively expensive and more complicated arc lamp transformer. Each coil consists of an iron core having a winding of copper wire, the terminals of which are connected to the constant-potential circuit. At different points in the winding connections are brought out and form terminals, to which the arc lamps are attached. When all the lamps are turned off the coil acts as the primary of a converter, which has its secondary open-circuited, and no current flows. When one lamp is turned on the choke coil effect is reduced by one-third the total amount, and some current flows through the lamp circuit. When a second lamp is turned on the choke coil effect is still further reduced, and when three lamps are in curcuit the economy coil may be considered as practically cut out, and the potential as being applied directly to the three lamps in series. Thus, it will be seen that complete and independent control is secured as satisfactorily and more economically than if a separate converter were installed for each lamp.

THE DEVELOPMENT AND UTILISATION OF THE ELECTRIC FURNACE.

The energy manifest in an ordinary arc light is of such a character and disposition as to suggest to the least thoughtful mind the possibility of its utilisation as an instrument of research and as a weapon of industrial advancement. Such is its simplicity that a casual observer might indeed assume that the application of the electric arc as a means of heating, in all cases where the game is not too trivial to be worth a costly candle, is only a matter of the merest detail. The fallacy of this assumption is, however, sufficiently indicated by the admirable collection of facts concerning early and recent types of electric furnace which we publish in another column. A reference to the translation referred to will show that, although the fundamental idea of boxing up an arc to check loss of heat by radiation, convection, and conduction is common to most of the forms of furnace which have attained even the modest honour of a place in a patent specification, yet the ways in which this common idea is carried out are, to speak metaphorically, as the sands of the sea shore. For a detailed description of the various forms of furnace which have been favoured by inventors, reference to the article in question must serve, but there are several points upon which it may be profitable to enlarge.

In the case of the well-known Cowles furnace — that standard refuge of the destitute illustrator—the original idea occupying the minds of its inventors appears to have been the fascinating notion of reducing zinc by internal heating of the retort charge. In the manufacture of zinc, as now conducted chemically, a mixture of zinc oxide and carbon is heated to a high temperature in a horizontal retort of refractory fire-clay and moderate dimensions. Seeing that the reduction of zinc oxide by carbon involves an endothermic reaction, large quantities of heat must perforce be transmitted through the walls of the refractory retort at the cost of much consumption of fuel and considerable wear and tear. The early COWLES' attempt (it dates from 1885) therefore exhibits a complete grasp of the inherent advantage of electric heating

Digitized by Google

as distinct from older and clumsier methods. The whole subject from this aspect has been amply dealt with in these columns within the last few years, and it is unnecessary now to do more than cite the example afforded by the Cowles patent as an indication of the direction in which the better class of inventor will prefer to work. It is needful for clearness of thought to preserve a sharp distinction between furnaces which are heated by electrical energy, but in which electrolysis is not intentionally performed, and those in which the execution of electrolysis is the primary object of the apparatus, and the heating of the contents of the vessel, into which the electrodes protrude a secondary and almost accidental concomitant. Cowles' furnace for the production of aluminium-copper alloys is a type of the electric furnace proper, and the Héroult apparatus is an example of an electrolytic cell having an electrolyte maintained in a state of fusion by a portion of the current passing through it. A practical and satisfactory method of discrimination consists in considering whether any given furnace the title of which is debatable can be fed with an alternating current. In 1888 and succeeding years there was a sudden activity in the application of the electric furnace proper to the performance of many chemical reactions which needed either much heat or a high temperature for their occurrence, and were normally conducted in closed vessels. Such were the methods of making phosphorus and carbon disulphide devised by Messrs. Readman, Parker and Robinson. Little has been heard of any of these hopeful attempts, save that which had phosphorus as its intended product. With regard to this it has been currently, though not formally, stated that the process proved entirely satisfactory, was bought for a substantial sum, and was forthwith relegated to limbo, those manufacturers who had a practical monopoly of the trade considering apparently that phosphorus was quite as cheap as is good for us. Until the year before last, no serious attempt seems to have been made to control the distribution of heat in an electric furnace in such a manner as to cause it to be uniform throughout the object or charge to be heated. Messrs. Street and Girard, by taking advantage of the dirigibility of the electric arc by a magnet, succeeded in presenting the arc which performed the heating, successively and rapidly to the object under treatment. The details of the arrangements contrived by these inventors will be found duly described in the Paper already adverted to. The command thus achieved over what is, under common conditions, a somewhat violent and spasmodic heating agent, has done much to render possible the application of the electric furnace to uses of a kind differing widely from those for which it has hitherto shown a limited adaptability. To turn a current into a firebrick box and subsequently empty that receptacle with the comfortable certainty that at least something will have happened to its contents if enough energy has been spent in its interior, is one thing. To carry out the delicate operation of baking carbon for use as electrodes, is quite another. The latter operation can only be successfully performed when the current can be controlled and the temperature of the furnace kept uniform throughout.

The development of the electric furnace has now reached a stage in no way sensational, but giving excellent promise of industrial utility. As yet, electrical heating is too costly to be indiscriminately used. Its applications are of necessity confined to those cases to which it does something that can be performed in no other way, or at least can only be accomplished with an inferior result. For arc lighting or for electrolysis the increased value of carbon, which has been baked at an exceedingly high temperature, is generally recognised. Much mystery has been maintained concerning the manufacture of carbon electrodes, but it is tolerably safe to say that no good product can be obtained without prolonged and vigorous heating. Of all forms of carbon, graphite is that which tends to persist as the temperature is raised; the diamond and charcoal are equally transformed into it. A half-recognition of this fact, coupled with a well-founded belief in the comparatively good conducting power of graphite, has led to the incorporation of this material into the carbonaceous masses destined to be moulded and burnt for electrodes of all classes. But graphite in its commercial form consists largely of clay, and its purification is somewhat tedious and costly. Indeed, it is pleasing to speculate whether most carbon makers have been alive to this necessity; regard being had to the amount of ash in some carbon electrodes, it seems possible that such drawbacks may have been overlooked. As an addendum to our knowledge of the tendency of carbon to assume the graphitic state on exposure to high temperatures, it has been recently shown that at the highest temperature attainable in an electric furnace, all substances other than carbon are dissipated and removed, with the result that the ends of the electrodes are not only graphitic but are also sensibly pure. It follows that a carbon plate or rod, of dense graphitic structure, good conductivity and unusual freedom from impurity, should be producible by exposing the ordinary moulded article to the temperature of the electric furnace. This is precisely the direction in which Messrs. Street and Girard have been working. They claim to have succeeded in producing a form of carbon, the conductivity of which is fourfold that of the untreated material, while its resistance to chemical action is also much enhanced. Taking the density of an ordinary carbon before heating as 1·98, they find that after treatment it has attained a density of 2·6. Should this figure be corroborated, it must be considered remarkable, inasmuch as the density of graphite obtained by ordinary means is not higher than 2·3, while the same figure has been observed as a maximum for hard gas carbon. Analysis of the carbons thus made indicated that the percentage of carbon transformed into graphite was about 80 to 85 per cent. The method of analysis is, however, by no means beyond criticism, depending, as it does, on the conversion of the graphite into the highly indefinite body known on the *lucus a non lucendo* principle as graphitic acid, which in no way resembles graphite, or comports itself as an acid. This point, however, may safely be left for future settlement. The precise percentage of graphite is not of moment provided a product has been obtained possessing many of the properties that would be exhibited by a sound coherent block of that form of carbon. When once criticism is allayed by the appearance, in a marketable form, of carbon which is nearly free from other elements than C and neither oxidises easily nor irregularly, nor breaks up when used as an anode for aqueous or igneous electrolysis, an ample field of application will at once be open. To take one of the most pressing cases alone: it is notorious that next to the want of a good diaphragm the most urgent need of those interested in commercial electrolysis has been a reliable unattackable anode. Hitherto the makers of moulded carbons have conspicuously failed to meet this want, and who shall say that it is not to the steady demand for retort carbon that the grossly inflated dividends of the gas companies are mainly due? In all seriousness, this latest application of the electric furnace marks, in virtue of its soundness of aim and seeming success, a hopeful epoch in a particular branch of electrical enterprise, which has until now suffered from over sanguine expectations rather than from indifference and neglect.

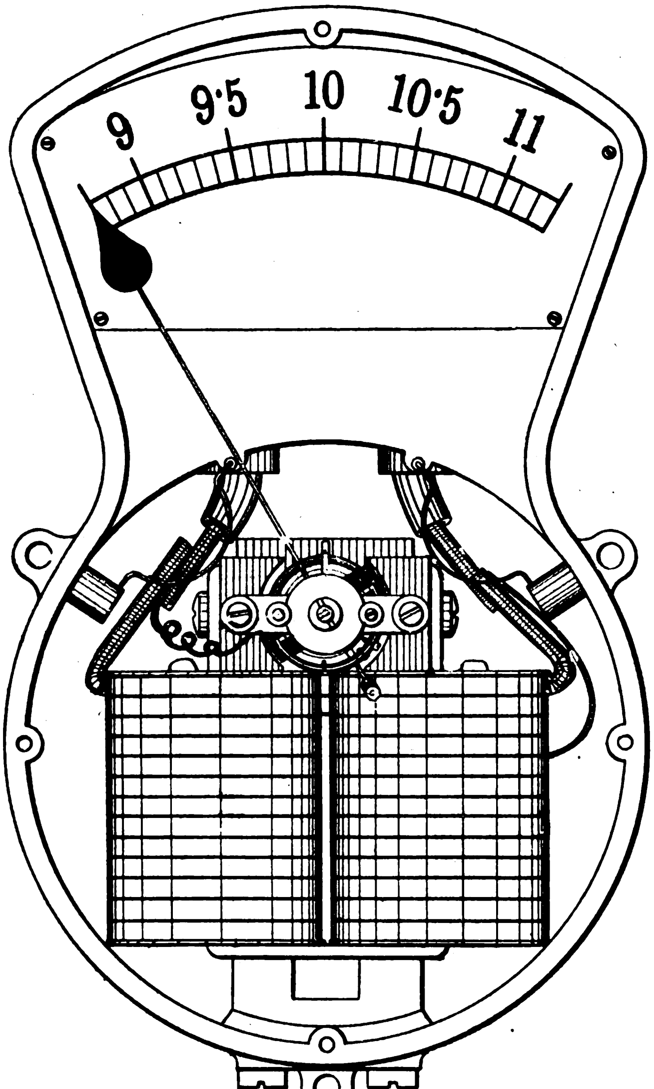
WESTON ARC-LIGHT CIRCUIT AMMETER.

The accompanying illustration represents a Weston arc-lamp ammeter, intended for use on constant-current continuous-current arc-lamp circuits. In the United States the extent to which this type of instrument is used is shown by the fact that one single American arc-lamp station has recently been supplied with 115 current gauges of this make.

The instrument consists of a moving coil carrying a pointer, which is lightly pivoted and kept at the starting end of the scale by means of two oppositely-wound spiral springs, through which the current leading to the suspended coil is passed. The permanent magnet of the ordinary pattern Weston instrument is, in the case of these instruments, replaced by an electromagnet, through the coils of which the main current of



View of Weston Arc-Light Circuit Ammeter with case removed.

the circuit is passed. The core of this electromagnet is of small section, so that it is practically saturated from the start. The moving coil is connected as a shunt across the terminals of this electromagnet coil, so as only to carry a very small proportion of the total current. By setting back the zero of the instrument, as it were, so as to be far beyond the left-hand side of the scale, and by employing a fairly weak spring, put under considerable initial stress, the needle is not moved from rest until a current of a very few per cent. lower than that necessary to bring the pointer to the centre of the scale passes through the instrument; hence a very small variation from the standard current, whatever it may be, is readily noticeable. A small polarised indicator shows a red or white disc behind a small circular window in the front of the case, and this serves to show whether the circuit has been connected up in the right direction, which is often of considerable use when connecting up a new arc-lamp circuit.

This ammeter, together with other instruments on the Weston principle, is being placed on the market by Messrs. Elliott Bros.

THE NANTASKET BEACH BRANCH OF THE NEW YORK, NEW HAVEN AND HARTFORD RAILWAY.

The first application of electric traction to a standard steam road was made on this line, and as it embodies some novel features, we give in the following a short description of it, the details of which we quote from the *Street Railway Review* of New York. The Nantasket beach railroad extends along a narrow peninsula, one side of which is known as Nantasket Beach. The length of the road is 6·91 miles, and of this there are 4·4 miles of curves in about 20 curves, the sharpest being one of 10deg. The line is almost level, the only grade being one of about 34ft. to the mile. The track is laid with 70lb. rails, with 15ft. space between the track centres, and the ballast is of stone. Each joint is bonded with a flexible bond of stranded copper, 7in. long, riveted into the flange of the rail. There are at present 10 stations, but others will be built to allow of stops about every quarter of a mile. The overhead trolley line is carried upon wooden poles set between the tracks. These poles are 30ft. long, 12in. by 14in. at the butt, and 10in. by 10in. at the head; and are set at intervals of 60ft. and 70ft. on the curves, and 90ft. on the straight track. At the cross-overs the posts are 180ft. apart, and side posts are used carrying a light iron truss over the track. The top of each pole is fitted with a cast-iron grooved cap, the grooves of which carry the six bare copper feeder cables. The poles are set in wooden boxes filled with concrete. The trolley wire is of unusual shape, being something like a figure 8 in section, and weighs 1lb. per foot. The lower surface is almost flat, and provides a large contact surface for the trolley wheel. This form has been given to the wire to permit of a more perfect attachment to the hangers, and to prevent the trolley from jumping when passing them. The brackets of two angle irons are bolted across the centre poles, and bent and bolted together at the ends. They are kept in position by an iron truss running through the cap. Each hanger is a double hanger, and gives an excellent support for the wire. The power plant is similar to other large modern direct-connected stations. The two generators are direct-driven General Electric 10-pole machines, having the armature spider keyed to the engine shafts. They are wound for a pressure of 600 volts at no load and 700 volts at full load, and are rated at 500 kilowatts at 100 revolutions per minute. The fields are of cast steel, and the armatures are of the "iron-clad" type, each winding being insulated, and then embedded in an insulated slot in the laminated iron armature body. The motor cars are of two types, the closed and the open. The closed cars are heavy baggage cars, and four are already equipped for service. The open cars resemble the familiar city trolley car, but have a flight of three continuous steps or foot boards. The closed motor cars are 42ft. long over all, and are built extra heavy, weighing each when fully equipped over 30 tons. Two of the four will have two motors on one truck, while the two others will have four motors, two on each of the two trucks. The open motor cars will have two motors. The motors used are of the General Electric type, especially designed for heavy work, and are similar to those in use on the Metropolitan Elevated Railroad in Chicago. The motors are 100 H.P. each, or 2,000lb. horizontal drawbar pull through a 33in. wheel. The current is brought from the trolley wires by a trolley wheel having an extra deep channel.

There are two controlling gears on each car. Immediately to the left of the controller is the air-brake handle. The compressed air for the brakes and whistle is furnished by an oscillating cylinder air compressor operated by an electric motor, which is controlled by a special automatic rheostat which regulates the action of the motor in accordance with the pressure in the tanks. A magnetic cut-out is also provided for the air-compressor motor. In the case of the closed cars the air pump is set just within the door. In the open cars it stands on the platform to the extreme left of the motorman. Behind the motorman and just under the hood is the car cut-out, which in this case is an automatic circuit breaker. A feature of the line construction is the system of interlocking switches, by means of which the overhead switch is thrown at the same time as the track switch. The line was opened for traffic on June 30th, and it is claimed that during the tests motor cars alone have been run as high as 80 miles an hour. A party of officers visited the road just before opening, and J. C. Sanborn, division superintendent, surprised the party by sending a train of 40 loaded gravel cars hauled by one four-motor car 40 miles an hour past the visitors.

SNAEFELL ELECTRIC TRAMWAY.

A little over a year ago an electric tramway between Douglas and Laxey was opened and has since proved a success in every way. Almost before this undertaking was completed an electric line to the summit of Snaefell was contemplated, and this line is now an accomplished fact. On Friday last the line itself was inspected by Col. Rich, R.E., and the electrical equipment by Major Cardew, R.E., both of whom expressed complete satisfaction with what they had seen. Snaefell is the highest peak on the Isle of Man, its summit being over 2,000ft. above the sea. A survey of the route was made by Mr. Fell, the engineer to the Company, which showed that a road could be run to the top of the peak with an average gradient of 1 in 12. A rack railway was possible, but the Company preferred to that system one proposed by Mr. Fell. Between the bearing rails a centre rail of greater strength has been laid down, this third rail being raised somewhat above the level of the outer ones; runners are placed on the bogies which clutch this rail horizontally. A gripper brake is also added, which, when necessary, seizes the central rail firmly and comes to the aid of the ordinary brakes. The contractors for the line were Messrs. Mather and Platt, of Manchester, the work being generally superintended by Dr. Edward Hopkinson, and on the spot by Mr. Willis. Mr. Herd, of Douglas, had the contract for laying the road; Messrs. Cammell and Co., of Sheffield, supplied the rails, the bearing rails being steel and 50lb. to the yard, and the central rail 65lb. to the yard. The gauge of the line is 3ft. 6in.

The generating station is situated midway between the two terminuses, and contains four Lancashire boilers and five horizontal compound engines of 100 H.P. each, each driving five 55-kilowatt shunt dynamos at a speed of 800 revolutions. These dynamos generate current at 550 volts pressure, and have magnet limbs of well-annealed cast steel. The generating plant is sufficient to run four or more cars, each loaded with 48 passengers, simultaneously up the line at a speed of 8 to 8½ miles per hour under normal conditions. In addition to the dynamo station there is an accumulator station at Laxey, which is equipped with a battery of 240 "chloride" accumulators. The overhead conductor consists of No. 0 B.W.G. hard-drawn copper wire, the wire being carried upon insulators supported in clips attached to cross-arms from steel poles; the return is by the rails, which are copper bonded. The Company has at present six cars of the open-air type, similar to those used on the Douglas-Laxey line. In addition to powerful brakes these cars are fitted with sanding arrangements. On each car there are four No. 5A Manchester motors, one being fitted upon the axle of each bogie. The motors are geared with single reduction steel gearing with pinion and wheel, and fitted with carbon brushes, the working parts being suitably boxed and protected. In the driver's cabin at either end of the car there is an emergency switch and ammeter with a suitable resistance for regulating speed and for use in stopping and starting; these are so arranged that the driver can always stand in the front cabin. Current is collected by means of two bar collectors.

AN ELECTROMAGNETIC EFFECT.*

BY F. W. BOWDEN.

Some time ago, under the direction of Prof. Perry, I was making some experiments suggested by Dr. Larmor. The following curious observations were made, and as Dr. Larmor thinks them distinct from his own object, I beg leave to bring them before the notice of the Physical Society. In Fig. 1, N and S are nearly cubical blocks of iron whose edges are about 6cm. long, forming the poles of an electromagnet. The field between N and S near the middle was about 1,100 C.G.S. A is the end view of a glass tube, 4mm. internal diameter and about 30cm. long, containing mercury and connecting two large mercury troughs, and a current of about 40 amperes was sent through it. A standpipe, B, 2mm. diameter, indicated the pressure of the mercury. When the current passes in one direction (out from the paper) the mercury rises 15mm. in B. When the current is reversed, the mercury falls 15mm. Reversing the magnetic field produces the same effect as reversing the current.

With the tube in the position shown in Fig. 2, the effects were of the same kind, but not so marked, the rise and depression being about 10mm. As the tube was lifted more and more out of the field, the effects became less and less.

The field being vertical, as in Fig. 3, the mercury *rose* in the standpipe when the current passed, and in whatever direction the current passed; reversing the current did not reverse the pressure-effect produced. Also reversing the field did not reverse the pressure-effect produced.

* Communicated by the Physical Society to the *Phil. Mag.*, August, 1895. A brief abstract appeared in our issue of July 19th, p. 397.

I again used a horizontal field, as in Fig. 4, the standpipe showing now the side pressure in the tube parallel to the field. It was my intention to let Fig. 4 really represent Fig. 3 turned through a right angle, and again the mercury always rose in the standpipe, whatever the direction of the current or field.

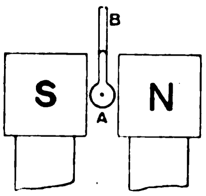

FIG. 1.

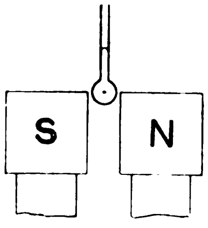

FIG. 2.

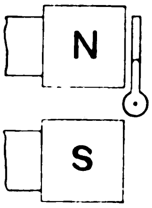

FIG. 3.

Lastly, I let four standpipes communicate with the middle of the tube. The current passing in one direction, the mercury in B rose, in C fell, and in A and D rose only momentarily during the starting of the current. When the current was reversed, the mercury in B fell and in C rose, and rose momentarily in A and D.

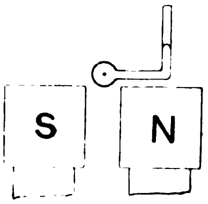

FIG. 4.

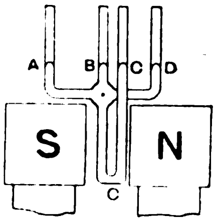

FIG. 5.

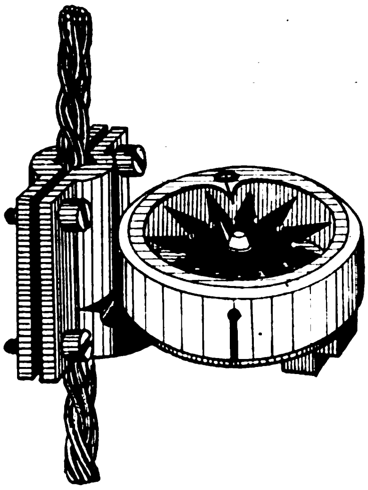
The non-reversible effects of Figs. 3, 4, and in the tubes A and D of Fig. 5, are probably due to curious motions of the mercury, but it seems difficult to understand how. They do not occur when the tube is far away from the magnetic field.

A LIGHTNING INDICATOR.

The accompanying illustration represents an instrument for the indication of lightning, and was invented by Herr Zielinski, of Berlin. It has, according to the German technical papers, been thoroughly tested by the German Imperial Post Office, and is now



employed at different post offices in Berlin, Munich, &c. The new House of Parliament at Berlin is also provided with several of these instruments. The arrangement of the instrument is very simple. In a glass-covered brass case a star-shaped compass needle swings on a steel point. The case itself is fixed to a bracket, which has a clamping arrangement at one end to allow of the whole apparatus being clamped to the lightning conductor. The magnetic star will set itself in the direction of the magnetic meridian, and when first erecting the instrument the red mark of the needle, or the point of the star opposite, should point towards the lightning conductor. The cover should so be put on that the pointer thereon occupies the same centre line as the red mark of the needle. If lightning

Digitized by Google

strikes the conductor, the magnetism of the needle is disturbed, and the needle becomes newly magnetised in the direction of the lines of force of the discharge. Under the influence of the earth's magnetism, or of that of the conductor itself, should this be of iron, the star magnet will settle down in a new position. A deflection of the needle is taken as evidence that lightning has struck the conductor. The pointer on the cover should afterwards be readjusted—that is to say, made again to cover the red mark of the needle. The instrument is then ready to indicate another discharge. It is interesting to note that this instrument, it is claimed, is only affected by lightning, heavy continuous or alternating currents passed through the conductor failing to influence it.

ELECTRICAL SUPPLY AT 230 VOLTS.*

To drive a coach-and-four through an Act of Parliament is generally an attractive performance, and a sporting metaphor is well applied to a feat which in itself is a deed of daring. From the small boy who darts between a policeman's legs on Lord Mayor's day, to some European Power who cleverly evades a treaty, the successful defiance of constituted authority has ever a peculiar interest. An active imagination, however, is needed to detect any sporting element in the recent achievement of the late electrical engineer to the Corporation of Bradford. Electrical supply in this borough was originally laid out, as our readers may remember, on extremely conservative lines. A simple two-wire system of conductors was used, and the only originality about the design was the use of 115-volt lamps. The five volts addition to the 110 volts, which was then the highest in ordinary use, did but little to extend the very inextensible system of distribution; but probably the inconvenience of a voltage peculiar to this town was hardly felt by the purchasers of incandescent lamps, since, of course, the local agents and dealers kept this kind of lamp in stock for the use of Bradfordians. The designer of the Bradford electric supply always argued that, so far from being utterly antediluvian, the system could be indefinitely extended, though whether by battery stations or by connecting districts in series or by dynamotor transformers was not disclosed. When at last something had to be done to meet the increased demand for electric supply, a five-wire system of mains was suggested. This was not carried out; but a three-wire system was constructed, the consumers, of course, enjoying their 115 volts as before. In the original system the dynamos, generating a trifle more than 115 volts, maintained this pressure between the two conductors. When the third was laid, electrically, if not actually between the first two, a difference of potential of 115 volts was maintained between each of the old outer conductors and the new middle one, one of them being 115 volts higher and the other 115 volts lower than the third or middle wire. The same dynamos, of course, sufficed, and were in effect coupled in pairs in series, the middle conductor being joined to the point between them. The consumers were all connected to one or other of the outer conductors and to the middle one. This constitutes what is known as the three-wire system. But so excellent is the service, so cheap the rate, so economical the management of the station, that the mains soon became overloaded again. To step from three-wire to four-wire would give but little relief compared with the great expense of laying another main, and altering the service connections, and something more had to be done, not only for the outlying districts, but for the very heart of the town.

In the meantime the art of lamp making, once sacred to Ponder's End, had been thrown open, and for every new manufacturer there sprang up half-a-dozen agents, mostly German, who sell unbranded lamps under various names. It was at one time thought that it would be a wise policy—though we are not aware that it was ever carried out—for a lamp maker to confine his attention and concentrate his skill upon 8 candle and 16 candle 100-volt lamps, but it now appears that Continental makers are ready to attempt to make almost anything that is asked of them, if only they can effect sales. The 8-candle 100-volt lamp was a long time in making its appearance. The monopolist company was no doubt right in declining to sell an untrustworthy lamp, lest it might spoil the reputation for good work which it was carefully building up, against the time when its patents should be valueless and its goodwill its best asset. But the art has slowly developed, and 4 c.p. or 5 c.p. lamps for 100 volts are possible. Multiple filament lamps have been used for very large candle-power, the filaments being in parallel, and being, in fact, merely a bunch of lamps in one globe. Double filament lamps have also been made for alternative use as 8 c.p. or 16 c.p., and, of course, when the manipulative skill in making such lamps has been acquired, it is just as easy to couple the two filaments in series. Take two 8 c.p. 100-volt filaments, mount them in series in a bulb, and you have a 200-volt lamp. We have observed that the fashion at Bradford, as dictated by the consulting engineer, is 115 volts. To make a good 8 c.p. 115-volt lamp is more than 15 per cent. harder than to make an 8 c.p. 100-volt lamp; but it can be done, though 8 c.p. lamps are not encouraged at Bradford. In short, within the past few months practicable 230-volt lamps have been made. Some have been sad failures, and we understand that the Edison-Swan Company declines to recommend them.

* From the *Engineer.*

To change from 115 volts to 230 would be a grand step, but the present consumers would not make the change to suit the convenience of their highly-respected Corporation. New customers who continue to apply for current can be dictated to; but it is not worth while to lay another set of mains for them, and any interference with the existing mains seems impossible, for what saith the Provisional Order? "The 'standard pressure' shall be fixed by the undertakers for every main, and shall not be altered except after notice to the Board of Trade, and upon such terms and conditions as the Board of Trade may impose, and after public notice has been given during a period of one month in such manner as the Board of Trade may require of the intention of the undertakers to alter the same." The coach-and-four feat is generally preceded by a careful scrutiny, resulting in the discovery of a minute crack, or, as it is sometimes called, a loop-hole. Turning back to the definition of a "main," we find that "The expression 'main' shall mean any continuous metallic conductor which may be laid down by the undertakers," &c. Let us leave electricity for a moment, and consider an analogy. Suppose the Board of Trade, wishing to define the gauge of a railway line, had ordered, "The 'standard gauge' shall be fixed for every line, and shall not be altered except after notice," &c. Somebody declares his "standard gauge" shall be 4ft. 8½in., and he will have two lines with a 6ft. way. The Board of Trade never mentions lamps in Provisional Orders, and we will imagine that in these railway regulations they never mention carriages. Suppose our friend wants to run a really comfortable saloon-palace car, and would like to use a gauge of about 16ft. Is there anything to prevent him? Certainly not. He builds a car to run on the two outer rails. Somebody looks up the definition of a "line," and finds that "The expression 'line' shall mean any continuous metallic rail which," &c. The late electrical engineer to the Bradford Corporation has hit on precisely the same device, which he will no doubt shortly introduce in his new sphere at St. Pancras. With the fear of a daily penalty of £10 before him, he has not altered the electrical pressure between any of the conductors, two of which, by the way, go to make up a main. The definition of the Board of Trade took it for granted that there must be two conductors, and it is to be noticed that when the third wire was laid at Bradford—a thing not contemplated in this Provisional Order—no regulation was infringed, no pressure was altered; everybody continued to use 115 volts, and to-day the old consumers continue to do so. But the new consumers, including all those who have been connected during the past few months, have no choice but to take 230 volts. They are not permitted to make use of the negative and the middle conductor at 115, or the positive and the middle conductor at the same pressure, but are connected on to the "outers," and now, without laying a yard of new main or raising the voltage in the station or elsewhere by so much as a steel knife and silver fork will generate when plunged into a beefsteak, Bradford can point to anything but an antediluvian system of continuous-current supply at 230 volts. Had the Provisional Order spoken of a standard pressure between the two conductors which constitute any given main, there might have been a little difficulty. There is nothing in the Parliamentary powers of the Corporation to prevent the use of this high pressure. The Bradford Order of 1883 permitted 200 volts, and the regulations issued in 1890 varied this to 300 volts, but did not allude to the three-wire system or to 115 volts. A new main with two conductors, having a difference of potential of 300 volts between them, might be laid any day; indeed, in the definitions of the regulations, "a low-pressure conductor shall mean any conductor in which the pressure between that conductor and the earth cannot at any time, if continuous, exceed 300 volts." So, if earthing the middle wire were practicable, there might be a difference of 600 volts between the "outers." The feat has been to use for service purposes a higher pressure, and yet to avoid making any change of the "standard pressure" on any main.

And what is the outcome of this achievement? We have only to turn to the advocates of alternating currents to learn the great economy of copper when high pressure is used. At Bradford the time is already talked of when a 230-volt three-wire system is to be general, that is, 460 volts between the "outers." Before that day, no doubt, the Board of Trade will be approached; for even if the whole generation of 115-volt consumers perish, their heirs, executors and assigns will want light; and unless the pendulum swings again, and the Board of Trade is swept away with other excrescences of a decayed Constitution, the Provisional Order confirmed by 46 and 47 Vict., Cap. CCXX., will remain in force. But to-day the Bradford Corporation relieve the congested current density in their mains. The new consumers who insist

Digitized by Google

on enjoying the municipal electric supply—as should all good ratepayers—must be connected, and in thus connecting them, they add only half the current burden to the conductors, and the £26,388 worth of mains, which, according to the analysis of our contemporary, *The Electrician,* constitutes 40·1 per cent. of the whole capital expenditure, becomes twice as valuable, or will so become when the change is completed. In so far as it is possible to continue business, and perhaps indirectly, through increased business to lower the price, the consumers may benefit by the change. Fortunately the fundamental laws of electricity are so arranged that the use of 230 volts is possible with existing appliances, excepting, of course, the lamp. A pressure of 230 volts will not jump an ordinary fuse, it will not even arc across the narrow gap of a tumbler switch. It will tingle if touched, a little more than 100 volts, but, as a matter of fact, one hardly ever touches it. We are not aware that the Bradford Corporation demand any higher insulation than is specified in their old regulations, but it is possible that some insurance companies may not be so easily satisfied. Regulations which define the insulation resistance by the observed leakage current, throw additional trouble on the contractor where high pressure is used, and possibly additional expense on the consumer. The saving in copper in wiring a house is a mere nothing, and would be completely absorbed by the better quality of dielectric.

The most serious result to the consumer is the withholding from him of the benefit of 8 c.p. lamps. It has been said of amateur photography that the expense of the amusement lies in the cheapness of the materials; conversely it may be said of domestic electric lighting that its cheapness lies in the expense of the supply. Economies that were never dreamed of when paraffin lamps or gas were used are regularly and readily practised by consumers of electric light, and not the least of these economies is the use of 8 c.p. lamps, especially for passages, staircases, bedrooms, and lamps for occasional use. The 8 c.p., or even a smaller lamp, is a most important factor in popularising electric light in small households, though for shops and offices a good distribution of light can generally be managed with 16 c.p., or even larger lamps. We understand that 8 c.p. lamps are not common in Bradford. The extra 15 volts may be the cause, or they may not be in fashion. Many a manager of a London supply company would sooner connect 100 8 c.p. lamps spread over three houses than the same number of 16 c.p. lamps in one house. The big house will be shut up for half the year, and the bulk of the lights will only be used when guests are being entertained. The small houses, on the other hand, will use a steady number of lamps nearly all the year round, and will not haggle for rebates. These are the consumers to encourage, and the economical lighting of small houses is made possible by the use of 8 c.p. lamps. We have before us an account which, we observe with regret, is not yet paid, for the quarter ending June 24, 1895, for a house in the west end of London. The house is, we understand, rated at £100, and has four 16 c.p. and nine 8 c.p. lamps, gas being used in the passages and basement. The account stands, amount due for supply of electricity, 12s. 3d.; rent of meter for one quarter, 5s. The accounts for the previous quarter were, we are informed, £2. 15s. 9d. and 18s. 9d. Is this the sort of house to be encouraged (supposing, of course, that the accounts are properly settled)? The inhabitants greatly value the advantages of electric supply, which is used for light and for other purposes. To afflict them with 16 c.p. lamps throughout would be either to raise the cost very considerably, or to push their already economical habits to very irksomeness. To compel a consumer to use double-filament 230-volt 16 c.p. lamps is to make him put up 8 c.p. lamps throughout, but with the inconvenience of being obliged to turn them on and off in pairs. Cooking and heating appliances, still rather expensive, will be more difficult to construct for 200 volts, for this is the pressure which will be generally employed if the fashion spreads. The step is very interesting; the use of higher voltage on the consumers' wires has long been contemplated, and the want of really good lamps has been the real obstacle; but until the Bradford Corporation compelled its new customers to experiment with such lamps as they can obtain, there was no inducement for lamp makers to attempt to manufacture a new article.

THE POSSIBILITIES OF ELECTRICAL PUMPING MACHINERY *

BY CHARLES A. HAGUE.

The convenience and controlability of electrical power, together with its simplicity of application to the work of pumping, commends it very strongly for use in isolated places, such as high-service systems in public water supply, wherein a comparatively small percentage of the total water supplied by the initial plant is needed for dwellings situated upon levels too high to be accommodated by the general pressure, and the question arises whether we shall put the entire system of the city under the highest required to force a supply to these higher levels, or whether we shall isolate the higher levels and handle the smaller percentage of water by itself.

This phase of water supply is not new. The portion of my subject relating to high service supply is a living question now perfectly practicable and applicable, destined without doubt to be largely employed in the near future. The application of electrical energy to the pumping of the main supply of a city of considerable size, although presenting many attractive features as far as the actual operation of the pump is concerned, is not yet within the possibilities on account of the absence of inexpensive methods for producing the necessary electric current, so that apparently in pumping large quantities for some time to come, compound, triple and quadruple steam pumping engines will hold sway. But the matter of transforming the energy of falling water by means of the turbine, and upon a large scale, with electrical energy at the end of a copper wire, is awakening interest far and wide to-day. It is beginning to offset very forcibly the proposition that it does not pay in the present state of perfection of the steam engine to go very far out of the way of regular commerce, to get the cheap power afforded by a falling stream.

How convenient it would be to generate an electric current at the main pumping station, with the boiler plant used for pumping the main water supply, then run the wires up to a point adapted to the high-service pumpage, and operate an electrically-driven pump. Of course, a high-service steam-pumping plant could be installed at the proper point, but that would mean expensive attendance, hauling of coal, ashes, supplies, &c.; and last, though by no means least, large quantities of smoke and dust spread over what are generally residence districts. There are cities where pumping plants are supplied with anthracite coal at double the cost of bituminous coal, to quiet the complaints of the owners of lawns and trees.

The method of switching on and off the electric current by means of the water level or pressure is one of the details that will occur to the hydro-electrical engineer. At the start the hydraulic engineer thought there was nothing to do but harness the electric dynamo and motor to a pump, and the task of pumping by electricity was accomplished. The electric engineer imagined there was nothing to do but harness a pump to his motor, and behold the result was obtained. But after a few attempts it was discovered that the pump holding such a stubborn and inelastic element as water, was subject to inertia, shock and variable power within short limits, quite at variance with the steady and uniform operation desirable for the best electrical results.

The point in the subject now reached is a very good one from which to view the future possibilities in using electrical energy upon a large scale for pumping water. The pump portion of the machine may be said to be in sight. Even now on short notice we can produce a pumping machine complete up to the binding posts for receiving the wires, and of as large capacity as has yet been produced in the steam machine. But who will step forward and furnish us with the current at a cost that will compete with the wasteful use of heat involved in the steam engine?

* Abstract of a Paper read before the American Waterworks Association.

The Influence of Gases Dissolved in the Electrolyte of a Silver Voltameter.—The June number of *Wiedemann's Annalen* contains, says *Nature*, a Paper by J. E. Myers on the influence of gases dissolved in the electrolyte of a silver voltameter on the weight of deposited silver. The author finds, as has previously been shown by Schuster and Crossley, that if the same current is sent through two voltameters containing neutral solutions of silver nitrate of the same strength and at the same temperature, one voltameter being in a vacuum and the other in air, then the weight of the silver deposited in the vacuum voltameter is, for a solution containing from 20 to 40 per cent. of silver nitrate, about 0·1 per cent. greater than that of the silver deposited in the other voltameter. For a 5 per cent. solution the difference is somewhat smaller. If the solution is saturated with carbon dioxide the deposit is about 0·055 per cent. lighter than when the solution is saturated with air. With nitrogen, however, the deposit is about 0·05 per cent. heavier than with air. The electrical resistance of a 5 per cent. solution saturated with air is practically the same as that of the same solution in a vacuum. With a current of more than 0·25 ampere, it is found than in vacuum an evolution of gas takes place at the anode. The author has also examined the grey deposit which is formed on the anode, and finds that it consists of pure silver oxide.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *August 9, 1895.*

A Westinghouse Combination.—The Westinghouse Electric and Manufacturing Company has entered into an arrangement with the Baldwin Locomotive Works of Philadelphia with respect to the construction of electric locomotives. The former Company will supply the electrical equipments and the latter the structure and other parts of the locomotives. The Baldwin Works are now busy upon plans for a new type of electric locomotive which the combination intends to produce. Two types of truck will be made, one for light work on elevated roads and the other for a heavier class of traffic and suitable for hauling from 12 to 15 cars. The design of the trucks is such that by fitting them with motors of the necessary power they may serve all the requirements of electric roads, from the lightest elevated at the maximum speed of 40 miles an hour, to the fastest suburban work of 90 miles an hour. The Baldwin plant has been the leading one in the United States during a long period for the manufacture of steam locomotives, and may be said to have originated most of the types now in use. The combination of two such great firms for the manufacture of electric locomotives will tend to accelerate their use, and furnishes a significant commentary on the present trend of electrical development.

Long Distance Electric Railways.—A contract for the building of an electric railway between Washington and Baltimore, a distance of forty miles, has been awarded. The cost of construction will be $3,000,000, and the road is to be completed with the year. Plans have been completed for another line between the same two cities, and it is expected that a contract for their execution will be signed within a few days, a syndicate of capitalists having offered to take $750,000 worth of the bonds. The former road is intended for an express service between the two cities in competition with the Pennsylvania and the Baltimore and Ohio steam railroads; the other line is intended to develop a section not now reached by steam roads.

The General Electric Manufacturing Plant.—It is beginning to be generally believed that there is something in the rumours which have been so persistently current during the past year with respect to the General Electric Company abandoning its present plant at Schenectady for a more favourable location. It is known that several advantageous offers have been made to the Company by capitalists interested in the development of manufacturing towns, and as the location of Schenectady is an unfavourable one for manufacturing purposes, it is not at all improbable that advantage will be taken of this opportunity to change the location of the plant. Several sites, it is said, have been offered, together with a large bonus for buildings and equipment, among which is one situated in a manufacturing town now being built up near Niagara Falls.

CORRESPONDENCE.

MAGNETIC UNITS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It seems to me a much more important matter that electricians should understand clearly, and agree upon, the magnetic quantities for which units are to be chosen, than that they should try to settle names for units which may not be wanted. The need for names arises in order that the practical electricians may have convenient handles to denote things that they have to deal with, and are not specially wanted by abstract thinkers, to whom a symbol is more acceptable than a name. It would therefore seem to be a matter of elementary common sense that practical engineers should be asked what units they want to have defined.

Before trying to find or adapt any names, let us try to ascertain what units are wanted, and agree upon their definitions. As a beginning permit me to make the following suggestions:—

1. Most important of all, and first to claim attention and definition, is the quantity on which the operation of every dynamo, motor, and transformer depends—namely, the quantity variously called the *magnetic flux*, the *total number of magnetic lines*, or the *total induction*. It is that for which I consistently use the symbol **N**, and for which, in defiance of the recommendations of the Frankfort Conference (which decided that Greek letters should be reserved for angles, and for specific quantities like specific inductive capacity), M. Hospitalier uses the letter Φ. Who will suggest a definition for the unit of this quantity? The C.G.S. unit is *one line*. I know one accomplished designer of dynamos who regularly uses the terms *kilolines* and *megalines*, and finds them very handy.

2. The next thing that logically follows is the *density* of the first-defined quantity—namely, that which goes by the names of *flux-density*, or *number of lines per square centimetre*, also unfortunately sometimes miscalled *the induction* (as though induction were not the operation of inducing, and already so defined by Faraday). Happily, whatever dispute we may have about the definition or denomination of this quantity, we all agree in using (though we quarrel over the fount of type to be used) for it the symbol **B**, or **B**, or 𝔅, or 𝕭.

By proceeding in this order we avoid all academic fatuities as to whether we mean the flux in air or in iron or anywhere else, or that part of it which would remain if the iron were removed. We must define it as that, whether in iron or air, which, when cut by the moving conductor, induces therein electromotive force.

3. We then want a definition of that which, when applied to a given configuration of magnetic matter, produces in it what we have already defined in (1); in other words, we want a definition of, and unit for expressing, that which goes by the names of *the line-integral of the magnetising forces*, or of *the magnetomotive force*. Here we encounter the great four-pi difficulty. Unless we are prepared to take the heroic step of four-pi-by-tenning our ampere, and adopting a new unit of current, then we *must* either four-pi-by-ten our ampere-turns, or else shunt off the difficulty by one stage, namely, by declining to consider it until we pass to the next unit. *Magnetic potential* would not be a bad term were it not that some sticklers for precision—notably my friend Prof. Ayrton—have for years, and with utmost consistency, declined to let us use the word *potential* (in its electrical application) for the whole line-integral of the electric forces in a circuit, and have persistently used it only for that part of the line-integral that lies outside the battery or dynamo. It has been in vain to point out that the P.D. is only an E.M.F.; it has been almost fruitless to abstain from using either of these hateful symbols. We have no recognised or universally adopted symbol for the whole, or total, or nett circuital electromotive force: even the sacred "E.M.F." is not reserved for this clear and unmistakable quantity. Magneticians have, therefore, the opportunity of setting a good example by fixing upon a clear, good definition of a *circuital* quantity, the separate parts of which can be separately defined *pro re nata*.

4. Just as (2) follows from (1) by dividing it by an area, so the fourth quantity requiring definition can be defined as a sequence from (3), but in this case by dividing by a length. The fall of magnetic potential per unit of length along the path will give us a definition of the quantity variously called *magnetic intensity*, *magnetic field*, or *magnetic force at a point*, and symbolised by **H**, or **H**, or 𝔋, or H. If we have, however, evaded the four-pi difficulty, and taken ampere-turns for (3), then its fall per unit of length will not be **H**, but **H** ten-over-four-pied.

5. When (1) and (3) shall have been defined, we then want a definition of the quantity which intervenes in the relation between them as applied to any magnetic mass of given circuital configuration. In other words, we want a definition of *magnetic resistance*, or *reluctance*, or else of its reciprocal

Digitized by Google

magnetic conductance or *permeance*. That such permeance or reluctance does in some kinds of magnetic media vary with the degree to which the flux-density has been pushed is quite immaterial to the need of definition and of a unit. One does not hesitate to define the specific refrangibility of a material because it depends upon the particular wave length of light that is being used. If we decide to define the *permeance* as the ratio of (1) to (3), or the *reluctance* as the ratio of (3) to (1), we shall still require tables giving statistical information as to the dependence of the specific permeance or specific reluctance upon the flux-density. Further, if we have shunted the four-pi difficulty from the preceding stages, we must finally face it now.

6. It will then only remain to define the specific quantity *permeability*, or *reluctivity*, as the case may be, by dividing (5) by a volume. Happily we are all agreed as to the symbol μ, in case *permeability* is chosen instead of *reluctivity*.

Will not some constructive engineers—Mr. Esson, Mr. Ravenshaw, Mr. Sydney Evershed, Mr. Mordey, or Mr. Andersen—tell us what things they think most important to be defined?—Yours, &c., SILVANUS P. THOMPSON.

UNIT FEVER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I see the scienticulists of the B. A. are at it again, and threaten us with a new series of units and names, while the original scienticulist (it is his own word) actually proposes to abolish 4π and leave us poor practicians to wallow in a sea of curling waves.

Lend me a little of your space to beg the B. A. folk, before going to work, to ask themselves what new units are wanted and who will use them? Let me tell them it is the practician who uses units with names to them, and at the present moment he wants a name for the unit of total magnetic induction and unit total magnetic force. He also needs—but not very badly—a name for unit self-induction, "henry" not having penetrated this side of the Atlantic.

Mr. Vignoles and I long ago suggested "thom" as a name for one "line of force" and "gauss" for one thom per square centimetre.

We very soon dropped the *gauss*, finding the *thom* alone was really useful in everyday work, and at Woodfield Works no one ever talks about lines of force. We think of the "*thom*" as a unit of squirming in the ether, and have consequently banished for ever all the paradoxical phenomena for which the line of force has been mainly responsible.

Now, I do not expect the B.A. to adopt the thom; it will not be easy to find a better word, but by all means let the B.A. endeavour to invent an equally good name itself. Only for Heaven's sake give us a word of one syllable. By the way, if it *must* be a dead and distinguished physicist, why not Thales—pronounced, of course, to rhyme with Wales?—Yours, &c., SYDNEY EVERSHED.

Hythe, Hants, August 17th.

INDIRECT ELECTROLYSIS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The indirect electrolysis which I described in an article published on June 29, 1895, in the *Génie Civil*, and mentioned by you on p. 480 of your issue of August 9th, is certainly "something more than the well-known fact" alluded to by Mr. Stepney Rawson in his letter which appeared in the last issue of *The Electrician*. Moreover, it has nothing to do either with "the well-known copper refining or with the gold-amalgamating process of Prof. Crookes." Evidently Mr. Stepney Rawson did not understand the working of this new electrolysis, and altogether missed the point. I presume he has not read the text of my article, but only the abridgement. The phenomenon which I have observed, and which is very easy to explain, goes much beyond the remarks of Mr. Stepney Rawson, whom I can assure that there is not much "in the case of a carbon plate" which he mentions. I will try to make the thing clear to him.

If, in a vat divided into three compartments, by means of two porous partitions, I fill with a strong chloride of sodium solution the outside positive and negative compartments, each provided with its electrode, and if I fill the central compartment, which does not contain any electrode, with a bisulphite of sodium solution, or with any other solution, such as a cyanide of gold and potassium solution, there will be chlorine liberated in the "anolyte," and caustic soda formed in the "catholyte," but no change whatever will take place in the central compartment. But as soon as I dip in this central compartment some metallic or conducting plates not connected at all with the anode and cathode of the lateral compartments, an electrolytic action takes place, which is quite independent of the direct electrolysis which is going on in the true positive and negative compartments. This electrolysis, which is working between the chlorine and the caustic soda compartments, is what I call the indirect electrolysis, and this is what Mr. Stepney Rawson has not seen.

I will give two illustrations of this electrolytic decomposition of a solution, and of formation of products other than chlorine and caustic soda. The first will be the reduction of a bisulphite of sodium to the state of hydrosulphite of sodium, which is a very powerful bleaching agent; the second will be the reduction of gold from its solutions.

The electrolyte in the positive and negative compartments will be a chloride of sodium solution. The central compartment contains a bisulphite solution in which zinc or other suitable metallic plates are immersed. As soon as the electric current passes, the chloride of sodium solution is decomposed in the usual manner, but the transfer of the ions from one role to the other does not affect in the central compartment the bisulphite of sodium, which is instantaneously transformed into hydrosulphite of sodium. From a reservoir the sulphite of sodium solution flows into the central compartments of several electrolysers connected in series, and is pumped back to the reservoir, which may be used as a bleaching tank, and from which it passes again through the same central compartments, where it recovers its bleaching properties. The solution may be used several times before it requires an addition of fresh sulphite of sodium to maintain its strength.

Is this production of hydrosulphite of sodium a well-known fact, as suggested by Mr. Stepney Rawson? The phenomenon does not require explanation, but it is quite a new thing, and this indirect electrolysis differs entirely from the known methods in electro-chemistry.

Other liquids can be worked in the same manner, and there are several valuable applications of this indirect electrolysis.

I will show now that the process I have found for depositing gold or any other metal does not resemble the methods alluded to by Mr. Stepney Rawson. The electrolyte is the same, *i.e.*, a chloride of sodium solution in the positive and negative compartments. In the central compartment I have a cyanide of gold and potassium solution, which circulates and yields its metal to perforated sheets of zinc or lead which almost fill up the compartment, and are not connected with the positive and negative poles. Some secondary reactions take place next to the negative compartment, but it would take too long to explain them, and to show how to avoid them. I will only say that the gold solution may be strong or weak; the deposition of the metal will take place until the solution is practically exhausted, say to the extent of 99 per cent.

I do not say that this indirect electrolysis, as a practical process, is good or not. But there is novelty, originality and utility in this decomposition of a solution between positive and negative compartments where another electrolytic decomposition independently takes place, and in spite of exhaustive researches I have been unable to find any mention of a similar process.—Yours, &c., EMILE ANDREOLI.

ARMATURE REACTIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your leaderette referring to the Paper of Prof. Elihu Thomson in last week's issue, you suggest that an unwound but smaller pole than that used by Prof. Thomson might be used in conjunction with one of my armatures,

Digitized by Google

This is very true, as I have proved by experience; several machines of my type being at work at different parts of the country and using a pole horn of this description. Some of those present may remember that I described such a pole in the course of my reply to the discussion on my Paper before the Institution of Electrical Engineers, although I think it does not appear in the printed report. The pole-piece will be found described in British Patent No. 10,298 (1893.) I may remark that I have lately been testing some 80-kilowatt machines which give a rising characteristic to the extent of 9 per cent. These machines have no series winding upon the magnets.—Yours, &c. W. B. SAYERS.

Glenwood, Bearsden.

THE BRIGHTON ACCOUNTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We beg to call your attention to the following slight errors into which you have fallen in your analysing our Revenue Account for 1894.

In Distribution Expenses you have included the sum of £399, the cost of work done for customers, which you will see by our statement of accounts is refunded, and has nothing to do with *repairs* or the *cost of distribution*.

In Rent, Rates and Taxes you have included the sum of £419, the cost of attendance and repairs to public lamps, which is also refunded, and have omitted to allow the sum of £63 for rents receivable. The total of these three amounts—£881—should be deducted from our total expenditure on *revenue account for the year*, thus bringing the expenditure down to £5,610, or 2·3d. per unit sold, now the second lowest figure obtained.—Yours, &c, ARTHUR WRIGHT,

August 16, 1895. Engineer and Manager.

[In the interests of accuracy and in view of the keenness of the competition for the position of premier "low costs" station, we are extremely sorry that the Brighton distribution expenses were inadvertently charged with some £399 they should not have been; at the same time, wiring work and lamp selling might well be placed under a special heading, if not done away with and left to those whose regular business it is. With regard to the inclusion of £419, the cost of attendance and repairs to public lamps, in the column headed "Rents, Rates, Taxes, &c.," Mr. Wright has omitted to state that we called attention to this fact in a special note, and also to observe that the column in question is intended, as is shown by the addition of the words *et cetera*, to include miscellaneous items not included under previous headings. It would be advantageous in cases where public lighting attains large proportions if *all* receipts and expenditure relating to it were kept entirely separate, as is so admirably done by the City of London Electric Lighting Company. Short of this measure it is impossible to ascertain exactly what the unit *sold by meter* actually costs to the seller—a feat, however, which we did not attempt to perform in our table.—ED. *E.*]

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

The following New Books and Editions of "THE ELECTRICIAN" SERIES *can be obtained of the Booksellers or direct from the Publishing Offices:—*

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

A LARGE-SHEET TABLE, giving full particulars of the Electricity Supply Stations throughout the Kingdom, can now be supplied mounted on stout board, with cord for hanging. Price: Varnished, 3s. 6d.; Unvarnished, 3s.—each post free. A Map showing positions of Supply Stations throughout the country is mounted on the back of the Table, and a Coloured Map of Metropolitan Electric Lighting Areas and a large sheet of Electricity Supply Statistics are also mounted on some copies, the price of which complete, post free, is 5s.

A SHEET TABLE showing Total Capital Outlay and Receipts and Expenditure for the year 1894 of the Statutory Electric Supply Undertakings of the Metropolis is now ready, printed on thick paper, price 6d. each.

A SHEET TABLE giving similar particulars in relation to Provincial Statutory Electric Supply Undertakings is now ready, printed on thick paper, price 6d. each.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell, with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

TENDERS INVITED.—Tenders are invited by the Vestry of Hammersmith, London, W., for complete schemes for public and private lighting, and for the supply of motor power in the compulsory area of the Vestry's Provisional Order. Particulars can be obtained of Mr. H. Mair, Surveyor to the Vestry. Tenders have to be sent in by 6:30 p.m. of Wednesday, Sept. 4th.

——— The Vestry of St. Mary, Islington, London, N., invite tenders for the wiring of the Vestry Hall and municipal offices. Particulars can be obtained from the electrical engineer to the Vestry (Mr. Albert Gay), 50, Eden-grove, Holloway, N., to whom tenders must be sent by 12 noon *on Tuesday next*, 27th instant.

——— The Commissioners for the Control of Lunatic Asylums, Dublin, invite tenders for wiring the Killarney District Lunatic Asylum for the electric light. Plans and specification may be seen at the Asylum or at the Office of the Engineer, Mr. W. Leake, 30, Victoria-buildings, Manchester, and tenders, addressed to the Secretary, Board of Control, Custom House, Dublin, must be in by 10 a.m. on the 30th instant.

——— The Electric Lighting Committee of the Wakefield Corporation invite tenders for the supply and erection of (*a*) boiler and fittings, mechanical stokers and engine, economiser, feed pump, injector, &c.; (*b*) steam alternators, condensers, oil filter, fittings, &c., steam, exhaust, feed, blow-off and sundry pipes, valves and water tank, &c.; (*c*) main switchboard and instruments; (*d*) cables, junction boxes, culverts, and trenching, &c.; (*e*) transformers and switchboard, &c.; (*f*) arc lamps and posts; (*g*) meters, and (*h*) overhead crane. Tenders, addressed to the Town Clerk, must be in by 2 p.m. *to-morrow*, August 24th.

——— The Portsmouth Town Council invite tenders for wiring the police stations at Buckland, Southsea, Portsmouth and Portsea, for the electric light. Tenders by the 27th inst. to the Town Clerk (Mr. A. Hellard), Town Hall, Portsmouth.

——— The Municipal Authorities of Braila, Roumania, invite tenders for the concession for (*a*) lighting about 64 kilometres of public streets by both electricity and gas, and (*b*) 64 kilometres of public streets by electricity alone, and also for the concession for the construction and operation of a network of electric tramways in the principal thoroughfares. Tenders to the Maire, Hôtel de Ville, Braila, by October 2nd.

——— The Urban Sanitary Authority of Chepping Wycombe (Bucks.) invite tenders for working their Provisional Electric Lighting Order. Tenders, by noon of October 14th next, to the Town Clerk, High Wycombe. Some additional information appears in our advertisement columns.

——— Tenders are invited for the erection of the superstructure of a machine shop, foundry and testing department, at Rugby, for Messrs. Willans and Robinson (Limited). Plans and specifications may be seen at the offices of the architect (Mr. T. W. Willard), St. Andrew's-chambers, Rugby, and tenders addressed to the Secretary, Messrs. Willans and Robinson (Limited), Picton House, Thames Ditton, Surrey, must be in by September 5th.

——— The General Direction of the French Posts and Telegraphs require tenders for the supply of 40 kilometres of double-conductor paper-insulated telephone cable. Tenders to the Direction Générale des Postes et des Télégraphes, 103, Rue de Grenelle, Paris.

Digitized by Google

TENDERS INVITED.—The Urban Sanitary Authority of the Borough of Bedford requires tenders for the supply of vulcanised rubber cables, in accordance with specification, which can be obtained from Mr. T. S. Porter, Clerk to the Authority, Town Hall, Bedford, to whom tenders have to be sent in by September 4th. Some further particulars appear in our advertisement columns.

——— Tenders are required for the establishment of a small central station for the electric lighting of the De Ruyter Fort at Willemstad. Tenders to the Café Het Schipperstuis, Willemstad, Holland.

——— The Queenstown Town Commissioners require tenders for the erection of works and the necessary plant for generating electric current for the public and private lighting of the town. Further particulars may be had from Mr. James Ahern, Town Clerk, to whom tenders must be sent by September 26th.

——— Tenders are required for lighting that part of the town of Thorne (Yorks.) included in the lighting area, from September 1st next to April 30, 1896. Tenders to Mr. C. Waller (Clerk to the Parish Council), by the 27th inst.

——— The Parish Council of Cheadle (Staffs) invite tenders for lighting the town quarter of the parish by electricity, gas or oil for a period of seven years. Tenders must be sent in to the Clerk to the Council (Mr. John Hulme) by Monday next, the 26th instant.

TENDERS ACCEPTED.—The Brighton Town Council have received the following tenders for the supply and erection of evaporative brass tube surface condensers, electrically-driven air pumps, exhaust and condenser piping for the electricity station :—

Wright's Patent Heater Condenser Company (*accepted*)	£2,476
E. Lar en	2,900
J. Fraser and Son	3,460

(All of London.)

The Town Council have also received the following tenders for the supply and erection of exhaust pipes, valves, &c , at their electricity generating station :—

H. North (Brighton) (*accepted*)	£489	0
J. Fraser and Son (London)	594	0
Reed and Son (Brighton)	540	0
J. Every (Lewes)	494	10

——— The Portsmouth Town Council have decided to accept the tenders of Messrs. W. T. Glover and Co. and the British Insulated Wire Company for cables for their electric light extensions. Subjoined is a complete list of the tenders received :—

For Conduits and India-rubber covered Electric Mains.

W. T. Glover and Co. (*accepted*)	£12,357	0	0
British Insulated Wire Company	13,812	0	0
Telegraph Manufacturing Company	13,026	0	0
Reid Bros	12,772	0	0
Fowler-Waring Cables Company	12,534	0	0
Johnson and Phillips	12,481	16	9
W. T. Henley's Telegraph Works Company	12,362	10	0
Siemen's Bros. and Co.	11,889	0	0

Messrs. Siemens Bros'. lowest tender was not accepted owing to the length of time required to complete the work. The tendering, it will be seen, was unusually close, due, in the main, to the clearness of the specification.

For "Compound" covered High-Tension Mains.

British Insulated Wire Company (*accepted*)	£490	£486
Siemens Bros. and Co.	634	623
Callender's Company	504	522
Fowler-Waring Cables Company	486	604
Reid Bros	459	565
W. T. Henley's Telegraph Works Company	437	538
W. T. Glover and Co.	400	486

These high-tension cables are required for the extensions in the St. Mary's and Milton-roads.

——— The Bolton Town Council have accepted the tender of Mr. W. Pollitt for excavation work in connection with the extension of their electric light mains to Saville Mill, Shifnall-street; that of Messrs. Hick, Hargreaves and Co. for clutch gear for the motor alternators, and of Mr. F. C. Jackson for the supply of stands for accumulators.

——— The Ashton-under-Lyne Town Council have accepted the tender of the London and Lancashire Electric and General Engineering Company for wiring and fitting up the Town Hall for the electric light.

APPOINTMENTS VACANT.—From our advertisement columns it will be seen that a thoroughly qualified lecturer in electrical engineering, telegraphy and telephony is required by the Croydon County Polytechnic. All further particulars may be obtained from Mr. J. W. Helps, the Chairman of the Committee.

——— The Municipal Commissioners of Singapore are prepared to receive applications for the position of municipal engineer. The engagement is for three years, with option of renewal, and the salary will be $500 per month, with certain allowances. Candidates who must be between 30 and 45 years of age), residing in Asia, must send in their applications to Mr. J. Polglase, municipal secretary, Singapore, by November 15th, but candidates residing in Europe or elsewhere may send in their applications to Mr. C. C. Lindsay, 167, St. Vincent-street, Glasgow, by October 15th next.

APPOINTMENTS VACANT.—The Governing Body of the Northampton Institute, Clerkenwell, E.C., are prepared to receive applications for the appointment of a principal. The salary attached to the office has been fixed at £600 per annum. Applications must be sent in by September 4th to Mr. J. J. Lambert, 8, Dowgate-hill, Cannon-street, London, E.C.

LIQUIDATIONS.—At a meeting on July 30th last it was resolved to wind up the Albert Lighting Company (Limited), of 110, Cannon-st, London, E.C., voluntarily. This resolution was confirmed on August 14th, and Mr. G. B. Gates, 12, Jerningham-road, New Cross, London, S.E , was appointed liquidator.

——— It has been resolved to wind up the Engineering Supply Company (Limited), Stockton Forge Works, Stockton, voluntarily. Mr. F. Brown, Finkle-chambers, Stockton-on-Tees, is liquidator.

——— All claims against the estate of Sir James Farmer and Sons (Limited) (in liquidation), mechanical and electrical engineers, must be sent in to the liquidator (Mr. A. Tongue), 86, King-street, Manchester, by September 14th.

DISSOLUTIONS OF PARTNERSHIP.—Messrs. J. Fleming, W. McFarlane, D. Leggatt and J. Heron, trading as electrical and mechanical engineers, Middleton, Lancs., have dissolved partnership. Debts by Messrs. J. Fleming and J. Heron, who continue the business.

——— Messrs. Gates and Hornibrook, mica merchants, Victoria Mills, Fairclough-street, and Backchurch-lane, Commercial-road, London, E., have dissolved partnership.

REMOVAL.—Messrs. Crompton and Co. have taken offices at Cornwall Buildings, 35, Queen Victoria-street, E.C., where their electric heating department will now be situate, the Brompton-road premises being kept open by the Kensington and Knightsbridge Company for the benefit of customers who may wish to see the various applications of electricity. The removal of Messrs. Crompton and Co.'s electric heating department to Queen Victoria-street is necessitated by increase of business, and the desirability of being in more central and accessible premises for inquirers, who come from all parts of the country and abroad to see these latest applications of electricity. Mr. H. J. Dowsing, who for the past three years has been in charge at Brompton-road, has taken over the new offices, and will be pleased to give any information in regard to this department.

OBITUARY.—We regret to announce the death of Mr. Peter Denny, of Messrs. W. Denny and Bros., electrical engineers and shipbuilders, which took place yesterday at Dumbarton.

ALSAGER (STOKE-ON-TRENT).—The Surveyor has just presented his report to the District Council on the lighting of this town by electricity. The report states that the Surveyor made a canvass of a number of houses in the district, with the result that 45 persons (who would require a total of 639 lights) were in favour of the introduction of the electric light, while 18 others favoured the introduction, but could not specify the number of lights they would require. Ten householders were neutral, eight against, and ten had not replied. The Chairman, in commenting on the report, said the promises were so encouraging that he thought the matter should be brought before the ratepayers. It was ultimately decided to ascertain the opinion of the ratepayers on the matter.

BATH.—A meeting of the City Council will be held on September 17th for the purpose of considering the question of an application to the Board of Trade for a Provisional Electric Lighting Order for the City.

BERLIN.—An Industrial Exhibition, to celebrate the jubilee of the recognition of Berlin as the Imperial capital, is to be held next year from May to October, in the Treptow Park, near Berlin. The ostensible object of the Exhibition is to demonstrate the progress and development of the various trades and industries of the city, and to exhibit its importance as a centre of commerce and industry. The exhibits will be divided into 24 groups, and there will be sections devoted to applied electricity, machine construction, shipbuilding and transport, building and engineering, textile, chemical, metal and india-rubber industries.

BOLTON.—At the last meeting of the Town Council it was stated that the receipts from the sale of current during the past month amounted to £180, making a total of £994 since the end of March. Seventy consumers are now connected to the mains, representing 5,800 lamps, and there are several other customers waiting to be connected up.

BRECHIN.—The Caledonian Electric Light Supply Company, and the Town and Village Electric Light and Power Company, recently notified the Town Council of their intention of applying for Provisional Electric Lighting Orders for this town. Some correspondence

Digitized by Google

has passed between the Town Clerk and the Caledonian Company as to the terms to be offered, but Mr. Murray has given notice that at the next meeting of the Town Council he will move that they should not entertain any proposition on the subject, the time not having arrived for the matter to be considered.

British Museum.—A considerable extension of the electric lighting of the reading room is in hand, the object being chiefly to assist the deciphering of the titles of books on the highest shelves, to which the public have direct access. These shelves are darkened by the gallery projecting forwards from the walls of the reading room. A new system of radiating these shelves has been devised, and the bulbs of the 40 incandescents which are to be used for this purpose are partially darkened so as to throw the light only upon the bindings of the books.

Canterbury.—At the last meeting of the Town Council a motion by Mr. Alderman Mason, empowering the Electric Light Committee to take such steps as they thought fit for carrying out the provisions of the Council's Provisional Electric Lighting Order, was adopted. The Committee are to report as to the best means of lighting the city by electricity.

Cablisto.—Reginald Bolton, an old cablist, contributes a chatty article on "The Pleasures of an Operator's Existence at Home and Abroad," to the columns of *Answers* for August 24th. The same writer was responsible for an article on a similar subject in the "Windsor Magazine" for July.

Dover.—Last week a meeting of the ratepayers of Snargate-street was held to protest against the postponement of the introduction of the electric light into this street, and, after the use of some vigorous and expressive language, a motion "That this meeting asks the Town Council to adhere to their resolution for lighting Snargate-street by electricity, and to carry it out at once," was unanimously passed.

Electric Lighting in Brazil.—The municipality of Itaparicá (San Paulo) proposes to light that town by electricity, and has invited Dr. O'Connell Jersey, engineer, to submit plans and estimates. The work of equipping the electricity station at Petropolis is making rapid progress, and it is anticipated that this town will be lighted electrically by the end of next month.

Electric Traction in Egypt.—Electric traction is making considerable progress in Egypt. It will be remembered that a company (Société anonyme des Tramways du Caire) was recently formed in Paris for the purpose of constructing and equipping about twelve miles of electric tramways on the Thomson-Houston overhead system in Cairo; and it is thought that Alexandria is likely to shortly follow. For the concession for the electric tramways from Cairo to the Pyramids, a distance of about ten miles, there were several bidders, a Belgian firm proving successful. An offer by a Frenchman to erect a funicular railway to the top of the Great Pyramid has been rejected by the authorities.

Electric Traction Statistics.—Interesting figures are to hand showing the important part played by electricity in the tramway systems of the United States. On a total number of roads amounting to 976, with a total mileage of 13,588, 10,363 miles are worked electrically, the next highest total being 1,914 by horses. The amount of capital stock of the tramways in the States is $784,014,206, the funded debt $552,125,505, and the debt per mile $40,600. The total number of cars is 44,745.

Empire of India Exhibition.—Messrs. Spagnoletti and Crookes have recently installed fire alarms on the Single-Wire Multiple Telephone Signal Company's (Saunders and Brown) system at the Empire of India Exhibition at Earl's Court. These alarms consist of three posts and two wall boxes so arranged that anyone can give an alarm of fire by breaking the glass and pulling a handle which rings a bell at the fire station, and also one of any required degree of loudness at the call point to assist in the detection of persons giving a wilful false call. The fire department at the Exhibition is under the charge of Mr. Harman, who has had great experience in the Metropolitan Fire Brigade, for which the same Company has supplied over 650 street call points. The same system is in use at Newcastle and many other towns. Local authorities throughout the country are gradually awakening to the necessity of providing effective means of promptly communicating with the municipal fire stations.

Great Yarmouth.—The report of the Electric Lighting Committee on the working of the Corporation Electricity Works for the past half-year shows a total loss of £164, or a net loss of £130, plus amount to be set aside for repayment of capital and interest. It has been decided to light the Fish Wharf electrically during the ensuing season at a cost of £50. The total number of lamps now connected to the mains is 5,122.

Harrogate.—A discussion on the report of the Electric Lighting Sub-Committee took place at the last meeting of the Town Council, and recommendations to the effect that the British Insulated Wire Company supply cables for the low-tension system, in addition to the tender already accepted; that a slow-speed flywheel alternator plant be adopted; that two Lancashire boilers, 30ft. by 8ft., be purchased; that a site on the north side of Oakbeck be utilised for the electricity works; that a small day-time plant be put down; and that, in the first instance, £800 be spent in providing junction-boxes and meters to 100 customers, were approved.

Hospital Lighting.—As stated in our issue of the 9th instant, the Governors of the Brompton Consumption Hospital, recognising the purer surroundings of the electric light, decided to light the whole of the hospital by electricity, and we understand that the work of installation has been entrusted to Messrs. Laing, Wharton and Down. The plant, which is to be fixed in the rear of the new extension buildings, will comprise a 145-volt dynamo, a large battery of accumulators and a Crossley gas engine. 1,209 incandescents will be used, and it is anticipated that the work will be finished by the beginning of November. The *City Press*, in commenting on this action of the Consumption Hospital authorities, says: "If not the first it is one of the first of the great London hospitals to adopt the electric lighting system, and there cannot be the least doubt that the change will conduce to the general welfare of the patients, who number upwards of 300. The hospital chapel has for some years past been lighted with electricity. There are 70 wards to be lighted, together with the nurses' dormitories, the doctors' bedrooms, an entertainment hall, and the administrative and other offices. The hospital is the largest of its kind in the kingdom."

Infirmary Lighting.—The contract for the electric lighting, supplying and fitting telephones, electric cooking apparatus, medical switchboards, electric bells and speaking tubes for the Lancaster Infirmary has been placed with Messrs. Drake and Gorham. The number of lights will be about 250.

Japan.—The British Consul at Yokohama, in his annual report, states the value of the imports of machinery from Great Britain during the year was £100,000. He also adds that it would be greatly to the interest of British manufacturers who supply electric light plant and apparatus if they had expert agents on the spot. In conclusion, the Consul remarks that electric light material is principally supplied from Germany and America, while telegraphic apparatus comes from Great Britain. Japan now makes dynamos for herself, the raw material for which is imported from England. The telephones employed in the country are all of home make, while the supply of galvanised iron wire is chiefly in the hands of German manufacturers.

Johannesburg.—The Berea Barnato Park, which is being laid out by the Johannesburg Waterworks Company, is to be lighted throughout by electricity, and a mansion to be built by Mr. Barnato, at a cost of between £30,000 and £50,000, is to be similarly lighted.

Lagos.—A Reuter's telegram states that a mass meeting, attended by 10,000 persons, was held on Saturday evening last in Tinubu-square, Lagos, to protest against the Electric Lighting Bill submitted by the Government.

Leytonstone (Essex).—A meeting of the Wanstead Slip Ratepayers' Association was held on Monday last to protest against the introduction of the electric light into the district by the District-Council. It was decided to appoint a deputation to wait upon the Council and lay the views of the Association before that body.

Liverpool.—No notice of opposition has been given to the Bill confirming the Provisional Order for extending the boundaries of this city. It will be remembered that the purchase of the Liverpool Electric Supply Company's undertaking by the Corporation was contingent upon the passing of this Bill in the present session of Parliament.

Llandudno.—The District Council at their meeting on Wednesday last discussed a report prepared by the Borough Engineer on his visit to Lytham to inspect the Hermite system of electrical sanitation which has been adopted by that town. The engineer in his report states that in view of the Council providing their own electric lighting plant very shortly, it would be unwise to lay down special plant at present for the purposes of this system, and recommends the Council to wait until more was known as to the results obtained at Lytham and elsewhere. The Council decided to adopt this course.

New Cable Steamer.—It is stated that Messrs. Lobnitz and Co., of Renfrew, have just received an order from the Japanese Government for a twin-screw steamer, which is to be completely equipped for telegraph cable laying and repairing.

Newport (Mon.).—The Town Hall was lighted electrically for the first time on Monday. The current is supplied from the Corporation mains, and 425 incandescents are used. The work of wiring and fitting has been carried out by the Electric Installation Company, of Victoria-street, London, S.W., at a cost of £517.

Ogmore Valley.—Electric lighting is making great progress in this district. It is reported that nearly all the streets, shops and places of worship are now lighted electrically, and the general opinion is that it is cheaper and much better than gas.

Digitized by Google

OSWESTRY.—A proposal to introduce the electric light into the Guildhall at a cost of £50 has been postponed to the next meeting of the Town Council.

PRIVATE HOUSE LIGHTING.—The Tayler-Smith Electric Company are installing the electric light at the town house of Mrs. Goldsmid, 45, Ennismore-gardens, London, W.

PROPOSED NEW AMERICAN CABLE.—A proposal has been submitted to the Hawaiian Senate by Mr. Spalding for the laying of an American cable between California and Honolulu, which stipulates for the payment of an annual subsidy of $50,000 for 20 years, exclusive of the cable franchise. The Bill passed the Senate on the 14th inst., the annual subsidy being fixed at $40,000 for 20 years. The construction of the cable, it is announced, now depends on the obtaining of a subsidy from the United States Government !

RHYL.—The District Council have been considering for some time past the question of the construction of a tramway. Three schemes were originally submitted, and, after consideration by the Road Committee, a system with gas motive power was recommended for acceptance. The Council, however, hesitated to endorse this plan, and decided to obtain the views of the ratepayers on the matter. Accordingly, a meeting was held on Tuesday, when Mr. Cheetham proposed that the system should be an electrical one. This was seconded by Mr. J. Morris, but the meeting was ultimately adjourned.

STORES LIGHTING.—The premises of the Tranent Co-operative Store Society, Glasgow, are now lighted electrically. Two arcs and about 120 incandescents are used, the installation having been carried out by Messrs. Higgs and Co.

SUNDERLAND.—The report of the Highways Committee presented at the meeting of the Town Council on Saturday, stated that the total capital expenditure to June 30th last on the Council's electric lighting works was £20,961. 1s. 5d., and it was anticipated that further extensions, &c., would necessitate the expenditure of about £23,000 additional. The committee also reported that there was a loss on the past year's working of £700. The Town Council have adopted the committee's recommendation that the salary of their electrical engineer (Mr. C. S. Vesey Brown) be increased by £60 per annum, and they have also decided to ask Prof. Kennedy to retain his position as consulting engineer at a remuneration of 2 per cent. on the cost of the extensions.

TARIFF CHANGES.—As a result of the recent Franco-Swiss Commercial Convention several modifications have been made in the French tariff on electrical machinery imported into that country from Switzerland. In future the duty on dynamos weighing 5,000 kilos, containing 50 per cent. of cast iron, will be 12fr. per 100 kilos, and on similar machines with less than 50 per cent. of cast iron, 20fr.; on dynamos from 2,000 to 5,000 kilos, with 50 per cent. of cast iron, 18fr. per 100 kilos; and on similar machines with less than 50 per cent. of cast iron, 20fr. On dynamos weighing from 1,000 to 2,000 kilos, 20fr.; from 50 to 100, 30fr.; and from 10 to 50, 80fr. per 100 kilos. Complete dynamo machines and detached pieces, worked parts of copper weighing less than 1 kilo, numbered and marked, fitted together or not, for machines weighing more than 2,000 kilos, 35fr.; from 1,000 to 2,000, 40fr.; from 200 to 1,000, 45fr.; from 1 to 200, 60fr.; and less than 1 kilo 75 centimes per 100 kilos. The new duty on arc lamps is 60fr.

TAUNTON.—In the report of the electrical engineer (Mr. H. W. Couzens), presented at the last meeting of the Town Council, it is stated that all the overhead wires in North Town and North-street have been removed, and that the underground mains are working satisfactorily. The demand for current is steadily increasing, and 73 additional 16 c.p. lamps were connected to the mains during the past quarter.

THE "NIAGARA" PULVERISER.—Messrs. Easton, Anderson and Goolden, of 3, Whitehall-place, London, S.W., and Erith, have secured the sole rights for the manufacture of the Niagara Crusher and Pulveriser (W. H. Coward's patent). This machine is adapted for the crushing of all classes of materials, and can be seen at work either at the Company's works at Erith or at the repairing shops, New Tothill-street, Westminster, S.W. The makers claim for the machine that it is very simple in construction, requires only small power, that no screens are necessary, and that it is very economical in working, to the extent, it is claimed, of 75 per cent. over the old type of pulveriser. Illustrated printed particulars can be obtained on request.

WORLD'S FAIR AWARDS.—It would really appear that those exhibitors at the late Chicago Exhibition to whom medals were awarded, are within measurable distance of receiving their long-delayed awards. According to latest information, the medals ought to reach the British exhibitors by the end of the current month. It is stated that the cause of the extraordinary delay (over two years) was due to the fact that the design of the artist who was originally chosen was not considered suitable, and another artist had to be selected. The medals, some 24,000 (!) in number, have now been made, and are ready for delivery.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

July 30, 1895.

14,481. T. G. POOLE and W. LOWRY. London. An improvement in imitation candles for electric lights.*

14,485. J. DEVONSHIRE. London. Improvements in alternating-current arc lamps. (C. E. Harthan, United States.)*

14,486. J. DEVONSHIRE. London. Improvements in four-motor reversing switches. (F. E. Case, United States.)*

14,492. S. PRIETO. London. An improved arc regulator for electric lamps.*

14,493. T. D. HOLLICK and F. W. HOLLICK. London. Improvements in electromotors and dynamos.

August 1, 1895.

14,577. C. B. CRAWSHAW and R. KENNEDY. Bradford. Improvements in multiple-circuit dynamo-electric machinery.

14,589. C. B. CRAWSHAW and R. KENNEDY. Bradford. Improvements in starting switches for electromotors, and in apparatus therefor.

14,615. E. DELANEY. Liverpool New or improved device applicable for use in connection with telephones.

14,627. A. C. BROWN and G. R. NEILSON. London. Improvements in electric fire-alarms.

14,638. J. C. CHAPMAN. London. Improvements in electric brakes. (W. B. Potter, United States.)*

14,639. J. C. CHAPMAN. London. Improvements in safety appliances for electric cars. (W. B. Potter, United States).*

August 2, 1895.

14,676. H. HIRST and W. E. GIBSON. London. Improvements in shade-holders for electrical and other lamps.

14,706. P. J. BUNAU-VARILLA. London. Mechanical and electrical apparatus for excavating and removing earth.

14,709. W. J. DAVY. London. Improvements in electric arc lamps.

August 3, 1895.

14,739. J. M. HUISMAN and H. C. GOVER. Glasgow. Improvements in holders for incandescent electric lamps.

14,792. THE ROGERS ARC LAMP COMPANY (LIMITED) and J. W. ROGERS. London. Improvements in electric arc lamps.*

August 6, 1895.

14,801. C. LUCKOW. Manchester. Improvements in the electrolytic production of oxides and salts which are insoluble, or practically insoluble, in the electrolyte.*

14,804. O. Y. RHODES. Leeds. Combined electric bell press, pear press, and holder.

14,840. F. W. DURHAM, Jun. London. Spray electrolysis.

14,842. W. P. THOMPSON. Liverpool. Improvements in electric condensers for use in polyphase and multiphase alternating current circuits. (C. S. Bradley, United States.)*

14,847. A. J. P. WHITAKER and F. G. TREHARNE. London. Improvements in electrically-insulated pipes and in the method of joining the same together, and in insulating cement or enamel used in connection therewith.

14,858. J. HARRIS. London. Improvements in electric meters.*

August 7, 1895.

14,902. G. FABBRO. London. Improvements in plates for secondary batteries.

14,914. W. J. BREWER. London. Improvements in overhead conductors for electric railways and tramways.

14,937. A. C. GORDON. London. Improvements in electric block signals for railroads.*

August 8, 1895.

14,973. W. WEBBER. London. Improvements in prepayment apparatus for attachment to gas, electricity, or other fluid meters. (Date applied for under Patents, &c., Act, 1883, Sec. 103, April 16, 1895, being date of application in United States.)

14,984. G. H. NISBETT. London. Improvements in the manufacture of insulated cables.

August 9, 1895.

15,024. E. ANDREOLI and G. ANDREOLI. London. Electrolytic production of amalgams, and their utilisation.*

15,057. SIEMENS BROS. AND CO. (LIMITED) and H. S. S. HARVEY. London. Improved means and apparatus for regulating or compensating for the variation of voltage in electric circuits.

August 10, 1895.

15,069. J. S. BIGGAR. Manchester. Improvements in and relating to telephony.

15,114. C. ERBEN and E. BERGMANN. London. Improvements in electric current meters.*

15,119. L. A. G. E. R. COMBOUL. London. Improvements in electrolysing apparatus.

Digitized by Google

August 12, 1895.

15,126. W. H. WILLATT. Hull. An improvement in secondary batteries

15,134. C. W. WASHINGTON. Huddersfield. Improvements in apparatus for covering electrical and other wires.

15,166. J. H. PELETAN and E. CHRISTOPHE. London. Improvements in electrophones applicable as electric lighters. (Date applied for under Patents, &c., Act, 1883, Sec. 103, February 13, 1895, being date of application in France).

15,174. L. B. ATKINSON. London. Improvements in single-phase and multiphase alternate-current motors.

August 13, 1895.

15,178. E. J. PIPER. Westminster. Improvements in electric arc lamps.

15,215. C. L. BUCKINGHAM. London. Improvements in and pertaining to telegraphic and other printing apparatus.

15,216. F. A. WEBB. London. Improvements in electric lighting attachment for gas burners.

15,225. J. DEVONSHIRE. London. Improvements in electric brakes. (William B. Potter, United States.)

August 14, 1895.

15,259. M. S. PICKSTONE. Manchester. Improvements in and connected with dynamo electric machinery.

15,260. F. G. ROBINSON. Liverpool. Improvements in electromagnetic separators.

15,276. E. P. ALLAM. London. Improvements in self-recording electric meters.

15,288. H. H. LAKE. London. Improvements in electric clocks. (Société Anonyme La Précision, Belgium.)

15,292. H. TIPPING and J. B. HAMOND. London. Improvements in galvanic batteries.

15,295. E. J. COUSTAM and L. GASTER. London. Improvements in the manufacture of illuminating bodies for use in electric lighting.

15,301. H. V. KEESON. London. Improvements in electric exploders.

August 15th, 1895.

15,338. R. H. BARNETT. Newcastle-on-Tyne. Improvements in electric arc lamps.

15,343. H. HIRST. London. Improvements in couplings or joints for the sheathing of electrical conductors.

15,363. C. E. SPAGNOLETTI. London. Improvements in electrical distribution.

15,365 W. H. DINGLE and J. URQUHART. London. Improvements in and relating to electric switches.

15,369 J. B. TORRES. London. Improvements in secondary or storage batteries.

15,371 W. ROWBOTHAM. London. Improvements in and connected with primary batteries.

August 16th, 1895.

15,431 D. MATHIEU. London. Improved electric apparatus for striking bells and the like or giving signals.

15,432 D. MATHIEU. London. Improvements in or relating to batteries.

15,433 D. MATHIEU. London. Improved electric apparatus for striking bells and the like or giving signals.

15,442 H. FARADAY. London. Improved means for supporting or suspending electroliers and the like, and for facilitating the raising and lowering of the same.

15,445 W. S. STIELTJES. London. Improvements in step-by-step printing telegraphs.

15,450. S. R. F. LURASCHI and E. LURASCHI. London. Improvements in electric telegraphs.

15,461. S. H. SNOWDEN. London. Improvements in or relating to telephone receivers.

15,470. C. D. ABEL. London. Improvements in asynchronous electrical machines. (La Société Anonyme pour la Transmission de la Force par l'Electricité, France.)

15,471. G. BAMBURY. London. Apparatus for converting alternating electrical currents into continuous currents.

August 17, 1895.

15,511. J. BROCKIE. London. An improved hand-feed projector arc lamp.

15,513. A. DONAY. London. Automatic regulator for dynamo electric machines supplying electric motors.

SPECIFICATIONS PUBLISHED.

NOTE.—All Specifications can now be obtained at the uniform price of 8d. each.

1894.

14,113. COOPER and OTHERS. Electric meters.

14,488. JEFFRYES and LEA. Arc lamps.

16,473. RITTER. Telephones.

16,916. TAYLOR. Lime and electric lights.

16,943. LANGLOIS. Ladder platform for telephone linesmen.

17,077. DANDO and GWYNNE. Lenses and electric lamps.

17,378. BLACKBURN and BOYDEN. Direct-current transformers.

17,542. LIARDET. Electric storage batteries,

17,808. LYON Arc lamps.

18,177. AUGUSTE GODCHAUX. Electrically actuated brakes, &c.

18,196. SIEMENS BROS AND CO. (LIMITED) (Siemens and Halske). Electric conductors.

18,273. IMRAY (Société Anonyme pour la Transmission de la Force par l'Electricité). Electric motors.

18,999. THOMPSON (Société M. Gaupillat and Co.). Electric fuses.

21,838. BEIN. Electrolysing chemical combinations, &c.

1895.

1,512. ROSS. Arc lamps.

6,756. BOULT (Rabbidge). Telephone apparatus.

9,708. DELANY. Electric heaters.

11,752. ANDREOLI. Electro-deposition of gold and silver.

11,842. NEWTON (Willms). Rheostats, &c.

12,229. VOIGHT and HAEFFNER. Electric resistances.

12,420. WEISE. Electric battery plates.

COMPANIES' MEETINGS.

Birmingham Central Tramways Company.

The annual general meeting of the shareholders of this Company was held on Wednesday at Birmingham, Mr. W. Neale presiding.

The CHAIRMAN, in moving the adoption of the report and statement of accounts, said each of the four departments of the Company (horse, steam, cable and electric) was worked from its own centre, and was practically independent. The steam and cable departments were progressive and profitable, and they mainly depended upon them for their revenue and for the dividend. The horse and electric departments were a constant source of difficulty and anxiety to the Directors. On the Bristol-road electric route they had run 138,925 miles, and had carried 1,154,345 passengers, a decrease of 149,488 ; and their receipts amounted to £9,093, a decrease of £641. Their loss on this section of the line was £1,735. 12s. 8d., and this result was principally caused by the bad weather during the past winter, and the fire at their terminus threw the traffic out of gear for some time. The omnibus competition on this route was very keen, but they were hopeful that this branch would soon earn a profit. They had made a very favourable contract for the supply of batteries, which, as the patent had expired, were falling in price. The maintenance of the tramways had cost £10,129, a sum far larger than they had ever before paid for upkeep. Although the dividend was small, yet he thought that the balance-sheet was one of the most satisfactory they had ever presented to the shareholders. They had set aside £10,000 for depreciation, which they were in a position to invest in securities outside their own business. In conclusion, the Chairman paid a tribute to the services of the late Chairman (Mr. Joseph Ebbsmith), and said that the present improved position of the Company was due more to that gentleman than to anyone else connected with the Company. A discussion on the general position of the Company took place, but the report and accounts were eventually adopted, and dividends of 5 per cent. on the Guaranteed shares and of 3 per cent. on the Ordinary stock were ordered to be paid. Messrs. J. T. Mantle and William Neale were re-elected Directors.

The Directors' report states that the reduction of the capital of the Company by lowering the nominal value of the Ordinary shares from £10 to £5 has been sanctioned by the Court. The receipts from the electrical department amounted to £8,960. 2s. 11d. The miles run were 138,925, and the passengers carried 1,154,345. The total profit for the year upon the various departments of traffic amounted to £55,924. 0s. 11d., against £52,804. 8s. 11d. for the previous year ; and the total working expenses cost of maintenance, repairs, &c., amounted to £40,917. 3s. 9d. The Directors recommend that, after the payment of the dividend on the Five per Cent. Guaranteed Stock, a dividend of 3 per cent. on the Ordinary shares be paid, and that £10,000 be placed to reserve and £671. 19s. 9d. be carried forward.

Exeter Electric Light Company (Limited).

The annual general meeting of the shareholders of this Company was held on Friday last at the works, Mr. W. H. Ellis presiding. The Directors' report, which the meeting was called to discuss, states that the accounts for 1894 showed a loss, notwithstanding a steady increase in the number of lamps connected. This result was due to the difficulty experienced in maintaining the supply during a large portion of the year. For some time the question of the stability of the Company's two large alternators had been a source of anxiety to the Directors, and during the last year the armatures of both machines had again to be renewed, but the second time since they were first put down, and as soon as these new armatures were put in, they proved to be utterly worthless, and later in the year a still further order for armatures had to be placed with the Brush Company, which, so far, had turned out to be somewhat better than the previous ones, although they could not be considered as wholly satisfactory. This had the effect of not only swelling up the expenditure on dynamos and increasing the bill for coal, oil, &c., but of largely augmenting the cost for repairs to other machinery through the necessity of keeping up the supply with plant only partially fit for running, and the result of these unexpected expenses had been to exhaust the small available balance of working capital. The Directors have, after careful consideration, come to the conclusion that the present site of the works is unsuitable to a large extension of the business, and to its most economical working with improved modern machinery,

Digitized by Google

and that any scheme of further financial support or reconstruction should provide for the erection of a new station in a more suitable position. Therefore, having regard to the present financial position of the Company, it appeared impossible to continue the business without a further large subscription of capital. Under these circumstances the Directors, after negotiations with two large London companies, suggest the following schemes:—

1. A transfer of all the shares and debentures of the Company to the County of London and Brush Provincial Electric Lighting Company (Limited) for a fixed sum in cash.

2. The erection of a new station, with modern machinery and an improved method of electrical distribution, the cost to be secured by prior lien debentures, the capital and interest of which shall rank as a first charge on the whole undertaking in priority to the present debentures.

If the second scheme were adopted the Directors urged that the present stockholders might have a chance of participating in any ultimate success which the Company might attain, which would not be the case under Scheme No. 1. As the existing debentures were secured by a mortgage of the whole of the property of the Company, neither scheme could be carried out without the consent of the debenture-holders, and a meeting of such debenture-holders had been called for the same day as the meeting of Ordinary shareholders.

At the debenture holders' meeting it was, we understand, decided to agree to the transfer of the shares and debentures of the Company to the Brush Provincial Company for the sum of £7,000, on the understanding that the Company's title would not be altered and the existing Provisional Order would continue to hold good. The basis of sale agreed to by the debenture-holders was a division of the net sum received in the proportion of 75 per cent. for themselves and 25 per cent. for the Ordinary shareholders. This proposal was favourably received at the shareholders' meeting and, in the course of the discussion, the opinion was strongly expressed by a shareholder that an opportunity should first be given to the City Council to acquire the works. He urged that a concern of such importance should be in the hands of the municipal authorities. Ultimately a resolution was adopted in favour of accepting the Brush Provincial Company's offer, but the consent of every shareholder to the arrangement has, of course, first to be obtained.

STATUTORY RETURNS, &c.

ECUADOR TELEPHONE COMPANY (LIMITED).—The annual return to July 11th has been filed; 5,000 shares have been allotted out of a nominal capital of £100,000, in £5 shares, and the full amount has been paid thereon.

ELECTRIC GUEST CALL COMPANY (LIMITED).—The statutory return to June 21st has been filed. The nominal capital of £5,000 is divided into 1,500 "A" and 3,500 "B" shares of £1 each. All the latter have been issued as fully paid, and 1,062 of the former class have been allotted.

ENGLISH ELECTRIC CARBON COMPANY (LIMITED).—The annual return to June 26th has been filed. The nominal capital is £10,000, in £10 shares, and of these 789 have been allotted. The full amount has been paid thereon.

GORSEINON ELECTRIC LIGHT COMPANY (LIMITED).—The annual return to May 31st has just been filed. Of a capital of £1,000, in £1 shares, 926 shares have been taken up. On these 15s. per share has been paid.

GREENWOOD AND BATLEY (LIMITED).—The annual return to July 6th has been filed. The nominal capital is £400,000, divided into 14,000 Preference and 26,000 Ordinary shares of £10 each; 11,066 of the former and 18,052 of the latter have been taken up, and 2,666 Preference and 4,666 Ordinary have been issued as fully paid. The full amount has been called on 6,934 Preference and 12,134 Ordinary, and £3 per share has been called on the remaining 1,466 Preference and 1,252 Ordinary.

HARGREAVES AND SHAW (LIMITED).—The statutory return to June 10th has been filed. The capital consists of £5,000, in £5 shares; 43 shares have been taken up, and the full amount has been paid thereon.

HOOPER'S TELEGRAPH AND INDIA-RUBBER WORKS (LIMITED).—The statutory return to July 1st has been filed. The nominal capital is £50,000, divided into 1,000 Preference and 4,000 Ordinary shares of £10 each. 1,000 of each class have been taken up, and the Preference shares have been issued as fully paid. The full amount has been paid on 498 Ordinary, £2 per share on 250, and 2s. per share on the remaining 252 shares.

INTERNATIONAL ELECTRIC STORAGE (LIMITED).—The statutory return to April 14, 1894, was not filed until July 31st. The nominal capital is £200,000, in 36,000 Ordinary and 4,000 Preference shares of £5 each. Only seven Ordinary shares were then taken up, but nothing was called thereon. The first annual return to July 10th last has just been filed; 9,500 Ordinary and 600 Preference shares were taken up, and 9,200 Ordinary had been issued as fully paid. The full amount had been called on the remaining 300 Ordinary and 600 Preference shares. As will be seen from our issue of the 9th inst., this Company has gone into voluntary liquidation.

LONDON AND HAMPSTEAD BATTERY COMPANY (LIMITED).—The annual return to June 27th has been filed. Of a nominal capital of £50,000, divided in 7,000 Preference and 3,000 Deferred shares of £5 each, 993 Preference and all the Deferred shares have been taken up, and the latter have been issued as fully paid. The full amount has been paid on the Preference shares.

CITY NOTES.

BABCOCK AND WILCOX (LIMITED).—The Directors of this Company recommend a half-yearly dividend at the rate of 15 per cent. per annum.

BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED).—The Debenture Stock transfer books of this Company are closed from the 21st inst. to September 3rd, inclusive.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended 18th inst. were £924, against £861 in the corresponding period of 1894, a decrease of £63. The total receipts for the half-year amount to £6,008, against £6,063 for the corresponding period of 1894, a decrease of £55.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).—An extraordinary meeting of this Company was held on Friday last, for the purpose of confirming the resolutions passed at the ordinary meeting on July 29th last, altering the Articles of Association so that the amount from time to time declared by the Directors as available for dividend might be applied in such a manner that there should be first set aside a sum equal to a preferential cumulative dividend of 7 per cent. per annum on the aggregate amount paid or credited on the "A" shares, and that out of the sum so set aside there should be paid a preferential cumulative dividend at the rate of 5 per cent. per annum on the amounts paid or credited as paid on the "A" shares without distinction. The alteration was unanimously adopted.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 18th inst. amounted to £1,374, and to £1,126 in the corresponding week last year, an increase of £248.

LIVERPOOL UNITED GAS LIGHT COMPANY.—At the annual meeting of this Company on Tuesday, Mr. Edward Lawrence, who presided, referred to the purchase of the undertaking of the Liverpool Electric Supply Company by the Corporation, and said he doubted whether they would be better able to persuade the public to take the more expensive illuminant than the electrical company had been. In spite of the progress of electric lighting the quantity of gas manufactured and sold by the Company showed an increase. To show their contempt for the competing illuminant the Directors announce a further reduction in the price of gas from 3s. to 2s. 10d. per 1,000 cubic feet, the reduction to take effect from the end of last quarter. The electric light is thus not only a direct but also an indirect boon to the community.

LONDON PLATINO-BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The half-yearly coupons, which fall due on September 1st, of the £100,000 Six per Cent. Debentures of this Company will be paid by Messrs. Glyn, Mills, Currie and Co., 67, Lombard-street, London, E.C., on and after that date. The coupons must be left three clear days for examination.

SMILLIE PATENT HIGH-PRESSURE PIPE AND TUBE COMPANY (LIMITED).—During the week this Company, which has a nominal capital of £75,000, in £1 shares, issued a prospectus inviting subscriptions for 25,000 shares. The Company has been formed to acquire the patent rights of Mr. R. D. Smillie (No. 17101 of 1893), and to construct, manufacture and sell steam pipes, tubes, and pressure cylinders. A brief description of the Smillie steam pipe was given in our issue of June 7th last, and the prospectus states that the desirability of obtaining a steam pipe which could be relied on to prevent the occurrence of accidents is fully recognised, and the numerous failures that have attended the use of copper pipes under modern high pressures in recent years have accentuated this desire. It is claimed that the Smillie pipe will obviate such failures and safeguard life, property, and machinery against loss or injury. The consulting engineer to the Company is Prof. George Forbes, and the Managing Director Mr. R. D. Smillie. The offices of the Company are Dashwood House, New Broad-street, London, E.C., and 145, St. Vincent-street, Glasgow, and the Secretary (*pro tem.*) is Mr. Alfred Ball. The lists opened on Monday last, and closed yesterday (Thursday).

SOUTH STAFFORDSHIRE TRAMWAYS COMPANY.—The report of this Company for 1893 and 1894 states that the present Directors are only responsible for the management since November 21st last. The receipts for 1894 exceeded those of the previous year by £528, and those of 1893 were £2,510 more than in 1892. The receipts per car mile for 1894 were 11·61d., against 11·90d. for 1893 and 13·47d. for 1892. This decrease is attributed to the increased car mileage run on the electrical sections. The total expenditure in 1894 was £1,653 more than in 1893, while the 1893 expenses were £2,294 in excess of the 1892 figures. This increased expenditure was largely caused, the Directors state, by the late Board consenting to the appointment of Receivers and managers in May, 1893. The Directors succeeded in obtaining an order from Mr. Justice Kekewich (which order was affirmed by the Court of Appeal) for the discharge of these Receivers and managers, and a declaration that the tramway was a public undertaking, and could not be broken up and sold in the same manner as an ordinary commercial concern, and that a Receiver of the net earnings only could be appointed. The Directors have commenced an action against Mr. Joseph Ebbsmith and Mr. W. J. Carruthers Wain (the late Chairman), claiming £15,000 damages and other relief, and this action is being pressed forward to trial as quickly as possible. The Directors state that, owing to the position of the Company, they were unable to hold the annual meeting in March, and it will, therefore, be necessary for the shareholders to sanction the meeting being held this month.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended August 16th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,753.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the half-month ended August 15th are £1,649, as compared with £1,638 in the corresponding period of 1894. The April receipts, estimated at £4,883, realised £5,024.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 902. [No. 18. Vol. XXXV.] FRIDAY, AUGUST 30, 1895. PRICE SIXPENCE.

NOTES.

THE magnetic unit proposals contained in Dr. OLIVER LODGE'S Report to the Electrical Standards Committee of the British Association, published in our issue of August 2nd, have so far given rise to considerable adverse comment, and have received but little commendation. We should be glad to see the balance redressed somewhat; discussion so entirely one-sided savours too much of killing the slain. Prof. EWING, it is satisfactory to note, shares our own inability to comprehend the need for new names and units; as he aptly puts it, they may be made legal tender by the fiat of a B. A. committee, but nothing less than a real want can make them current coin. Mr. ESSON also fails to properly appreciate the gravity of the unit question, and protests with a vigour that becomes a practical engineer against a "senseless multiplicity of terms." Mr. RAVENSHAW is, indeed, a *rara avis;* he would be sorry to lose 4π. Mr. ANDERSEN, like most dynamo designers we suspect, has a system of units all his own. Of course, nothing short of an Order in Council can compel the adoption, even in public, of any particular system of magnetic units, and even then every dynamo builder could use in private the particular mixture of inches and centimetres, pounds and grammes, he had grown used to. The question is:—To make the best choice of definite symbols, units and designations adopted for international use, so that there may not arise in the near future a magnetic Babel? Whether Dr. LODGE'S proposals commend themselves to English mathematical physicists we shall learn more or less clearly at Ipswich; that they do not meet with much favour among English text-book writers, experimenters, and dynamo builders is tolerably evident already.

IN an article which we publish this week, Mr. J. WHITCHER deals with some of the principal questions involved when the separate conductors of an alternate-current system are armoured with iron. The author directs attention especially to the self-induction, and the consequent drop in the conductor and hysteresis loss in the iron. The extensive use of concentric and triple-concentric conductors puts a large proportion of alternating-current conductors beyond the range of Mr. WHITCHER'S remarks; yet, as he says, there are a great many places where single mains are run in iron piping, where a knowledge of the inductive drop due to the iron would be valuable. The tables and formulæ which accompany this article in some measure supply this information; though, from the fact that these are deduced from theoretical considerations based upon sine-wave currents, their application to any particular case must be made with necessary modifications. Mr. WHITCHER finds that under practical conditions the loss due to hysteresis is not of great moment and is comparable with the Foucault current loss in the iron. He does not, however, investigate a more important effect, viz., the extra copper loss due to the increased wattless current caused by the self-induction arising from the iron armouring, though it will be easy for the reader to deduce the expressions for the copper loss from the data which Mr. WHITCHER supplies.

AT the meeting of the shareholders of the Birmingham Central Tramways Company last year, the then Chairman spoke of the accumulator car venture of that Company as one of "mingled difficulty and hope," and went on to say that he had "distinct reason to believe that the Electric Department had seen its worst days"; a very restrained dose of prophecy for a chairman, seeing that a *bonâ-fide* profit of over £1,200 had actually been earned by accumulator cars for the first time in history. The circumspection exhibited by Mr. EBBSMITH has, however, been thoroughly justified. His successor had this year to chronicle a loss of £1,735, not attributable, of course, to the system of traction adopted, but to the bad weather, fire at terminus, and keen omnibus competition, a dismal tale which concluded in the customary manner, "they were hopeful that this branch would soon earn a profit," and "they had made a very favourable contract for the supply of batteries." It is very evident that accumulator traction still remains a tangle of hopes and difficulties; the former being served out to investors, the latter being left to engineers to solve—if they can.

THE main financial features of the past twelve months' operation of the battery cars at Birmingham are as follows:—With a practically stationary mileage, the receipts have decreased some 6 per cent., and the expenses have increased some 27 per cent., the total cost of the car mile having grown from about 14¾d. to nearly 18½d., the difference being due quite as much to increased wages as to increased cost of material. It is not considered particularly chivalrous to strike a man when he is down, and acting up to this laudable tradition we will not unduly enlarge on this matter. Suffice it to remark that the Birmingham line is not an abnormally trying one, that several types of cell have been employed, and

Digitized by Google

that these experiments on a commercial scale have now lasted several years. And yet with the practical possibility of accumulator tramway traction still an open question, there are individuals who affect to believe in electric omnibuses. Would it not be as well to learn to walk before attempting to run?

A VALUABLE little article on an important branch of central station practice recently appeared in our contemporary, the *Electrical Engineer* of New York, and is given practically *in extenso* in our columns this week. We use the term *central* in a special sense, for the practice we refer to consists in the supply of electrical energy from one large station to a number of minor ones, at times when these latter are under light loads. So far back as August, 1892, our New York contemporary pointed out the advantage which might accrue to the then new station of the Edison Electric Illuminating Company, of Boston, U.S.A., if this station were cross-tied to the older and comparatively uneconomical ones in its vicinity, so that the latter might at times derive power from the former. The good advice was acted upon in 1893, and has been followed ever since. The effect of this practice upon station economy is recorded in the article to which we refer. As would be only reasonable to expect, the change of practice since 1893 has been a step in the direction of improved economy.

THE recent amalgamation, in so far as electric railway work is concerned, of the Baldwin Locomotive Works of Philadelphia with the Westinghouse Electric Manufacturing Company of Pittsburg, leads one to wonder whether, in that remote future when our trunk railway lines will have become electrical, similar business amalgamations will be made in this country. In England, locomotives and most other heavy railway apparatus are, as a rule, made by the railway companies themselves; and not only so, but railway companies are permitted to manufacture for sale. It would seem, therefore, more likely that the owners of extensive works, such as those at Crewe, Derby and Swindon, would not only find themselves able to dispense with the aid of any electrical firm, but might very well indulge in a little manufacturing for the general market. This latter contingency, however, is not less remote than the general working of our trunk lines by electricity upon which it depends.

IN a Paper read before the American Institute of Electrical Engineers, Mr. C. P. STEINMETZ expresses his opinion "that the names *polyphase* and *single phase* are really wrong, and the latter name meaningless, since *phase* becomes a meaning only as *difference of phase*." Thus Mr. STEINMETZ thinks that, like a quarrel, it takes two to make a phase; but the distinction is, we think, a little too finely drawn. The same kind of objection might be raised against the word *polycycle* which he proposes to substitute for *polyphase*, for it might be said that there is really only one cycle, all the cycles being identical, and differing only in phase. There is no good in straining at gnats, even though we do not swallow camels.

IN this country, where the tramcar is known only in one or two stolid business-like patterns, varied slightly only in summer time by the breezy open cars to be seen in many of our provincial towns, we have some difficulty in realising the gay profusion of variety in the cars on many of the American street lines. The gaiety is more in the variety than in the purpose of many of these cars; for the sober hospital or ambulance car and the gloomy funeral car are sombre enough. Besides these there are the mail cars with their Government colours, and scarcely a town but has its batch of decorated cars for the fashionable and popular "trolley parties." Newest of all is the ice-cream car, which, ornamented with coloured electric lights on its sides and roof, and fitted with a bar at which ices and drinks are retailed, flits merrily round the town. We wonder where next inventiveness and the love of creature-comfort will lead.

Electric Heating in the Workshop.—It is stated that reheating molten steel in the ladle by means of electricity has been successfully accomplished at the Homestead Steel Works.

Laval Steam Turbine.—The New York Edison Company is introducing into its new Twelfth-street station, now in course of construction, two 300 H.P. Laval steam turbines, also a storage battery.

The Telephone Service.—In reply to a question in the House of Commons, Mr. Hanbury stated that it was probable that the Government would carry out the recommendation of the late Telephone Committee by appointing a committee in the next Session to consider and report upon the evidence already taken.

A Substitute for Tramway Motor Commutators.—According to the *Electrical World* of New York, in a patent recently granted in America for an electrical motor, the inventor dispenses with the necessity of the "troublesome commutator" by substituting for it a make-and-break device through which the whole current flows!

Motor Equipment of American Government Printing Works.—According to the *Electrical Review* of New York an important change is about to be made in the government printing office in Washington, where the whole of the heavy shafting and expensive belting hitherto employed will be removed to make room for an electric equipment.

Weather Predictions by Telephone.—According to the *Western Electrician* Prof. E. B. Garriott, the new head of the Weather Bureau at Chicago, announces that the Bureau will henceforth make particular efforts to serve those interests that are likely to be injuriously affected by unusual weather conditions. Timely warnings by telephone are to be features.

Brown, Boveri and Co.—On the 24th inst. this firm completed at its works at Baden, after only 3½ years' existence, its 1,000th dynamo, the total capacity of these machines amounting to 55,000 H.P. During the same period the branches of the firm at Paris and Frankfort-on-the-Main have turned out 500 dynamos. At the Baden works there are about 500 employés.

Thomsistiana.—A statement is going the round of the Press to the effect that Lord Kelvin's name will survive in the Spanish language in the new word "*thomsista*," which is to mean "practical electrician," and has now come into general use, being derived from Thomson. There is a "School of Thomsists" in Cadiz, and the establishment of one in Madrid is being vigorously advocated.

Repair of the "P. Q." Cable.—The cable steamer "Faraday" left Woolwich on Wednesday, the 28th inst., to repair the former "P. Q." cable broken in mid-ocean in 2,500 fathoms. On her way she will first repair the Penzance-Brest section, which is interrupted. These breaks make the third which has occurred in this cable system since its acquisition by the Compagnie Française des Cables Télégraphiques in January last, and for which they have found it necessary to invoke outside assistance.

Retention of the Capital.—It is often a debatable matter whether the initial of a personal name which has been applied

Digitized by Google

to some common object, as, for instance, a Nicol prism, should be spelled with a capital or a small letter—Nicol or nicol. An engineering contemporary reproves another contemporary for printing "telford paving," and thinks it should have been "Telford;" but it immediately afterwards speaks of "macadam paving" with a small "m"! It is probably the tendency of the capital letter, in all such cases, ultimately to be replaced by the small letter.

Relative Heating Properties of Various Sources of Light.—The following comparison, due to Prof. Palaz, will, the *Engineer* thinks, be useful to electrical engineers in presenting the advantages of electric lighting from the standpoint of coolness. The figures quoted are relative to a given quantity of light:—Arc light, 4; incandescence light, 14; kerosene, argand burner, 331; gas, argand burner, 380; candle, 473; gas, butterfly burner, 511. The heat question is a very important one, but it is as nothing compared with the question of vitiated atmosphere. In this respect, of course, electricity compares still more favourably with all other sources of artificial light.

Liquid Fuel.—It is stated by the *Engineer* that an improved method of burning liquid hydrocarbons or creosote oil has been patented. The intimate mixture of the hydrocarbon vapours and air is ensured by supplying the air from behind the fire bridge. The pipes from the blower pass under the fire bars of the furnace and terminate in fire brick chambers behind the fire bridge; from these the air issues through numerous holes, which are towards the furnace. In this way the already heated air is, as it were, sprayed into the furnace, where it meets the oil vapour, which is introduced above the fire bars, either from sprays in the front of the furnace or from perforated pipes running along the furnace walls.

Burying Wires in Boston.—The Commissioner of the Wire Department in Boston is, says the *Street Railway Gazette* of New York, extending his policy of burying wires and has determined what must be done in this direction during 1895. The feeder wires of the West End Street Railway Company are to be put under ground as far as Adams-square. It is the policy of the Department, where no conductors cross the trolley wires, to order the removal of guard wires. The West End Company would be glad, it is stated, to remove all guard wires, but the Wire Department has made the announcement that it is not yet ready to permit their removal, except in streets where other wires are so distant as to make it impossible for them to come in contact with the trolley wires.

The Thunderstorm of August 22nd in Jutland.—Our Copenhagen correspondent writes that a terrific thunderstorm, unprecedented in its effects, passed over a portion of northern Jutland during the night between Thursday, August 22nd, and Friday, August 23rd, causing the loss of several lives, over 50 fires, and the destruction of a great many horses and cattle in the fields. The storm came from the North Sea, and the principal sufferers are the small towns and villages on both sides of Limfjord. At Thisted 52 violent flashes were counted within two minutes; the lightning struck incessantly, and the inhabitants rushed out from their houses, although it was pouring with rain at the time. From Aalborg 12 fires could be observed, and a postman driving from Thisted to Aalborg saw 26 fires *en route*. At Säby the telephone suffered severely. The loss of property is very serious.

Thermal Conductivity of Copper.—Some experiments have been made by Messrs. R. W. Quick, C. D. Child and B. S. Lanphear, of Cornell University, with a view to determine the relation of the thermal conductivity of copper to its temperature, at low temperatures. The results show that an increase in thermal conductivity takes place with rise in temperature, which is in accord with the previous results obtained by Tait, Lorenz, Kirchoff and Hausemann, but is contrary to those of Stewart, who found a decrease in thermal conductivity with rise in temperature. Stewart, however, worked with electrolytically-deposited copper, while the metal used by the other investigators was obtained by dry processes. It is noteworthy that although, at ordinary temperatures, the thermal conductivity of metals is parallel with their electrical conductivities, yet with varying temperatures diametrically opposite changes in conductivity occur.

Fatality on the Portrush Electric Tramway.—An accident, which resulted in the death of a young man named Waller, aged 23, a native of Blackburn, occurred on Monday evening on the electric tramway at Bushmills. It appears that he and a friend were coming from Belfast around the coast to Portrush on bicycles, and when about a few hundred yards beyond the tramway station on the Portrush road, it is believed that the deceased, endeavouring to run his bicycle on to the tram line, struck the elevated kerbing of granite, about 5in. in height, which at this place divides the county road from the tram line, and was pitched over the machine on to the elevated third rail. His companion, who was a few yards in advance, hearing the deceased shout, returned to his assistance, and found him lying on the rail, and his bicycle on the top of him and also in connection with the rails. The unfortunate man was immediately removed to the waiting room at the station, where, despite the efforts of two doctors, he expired shortly afterwards. In trying to release the body from the rails the deceased's companion received a severe shock.

The Buffalo-Niagara Franchise.—After what seems to be an entirely needless delay, says the *Electrical World* of New York, the Buffalo municipal authorities have again taken up the matter of the terms of the franchise to be offered to the Niagara Company, and have made several notable concessions. The most important of these is in the section relating to the cost of electrical energy for municipal purposes. As originally drawn up, this section required that power should be sold to the city for £4 per annual 24-hour horse-power, and that street arc lamps should be supplied for £10 per year, or current sold to the contractors for city lighting, so that they could supply arc lights at that price; in the amended franchise these provisions are omitted. Another omission of importance is in the section relating to the life of the franchise, the clause governing the purchase of the plant by the city at the end of 25 years being left out, thus leaving the grantee at liberty to negotiate terms when the occasion arises. Another concession permits the Niagara Company, if it accepts the franchise, to transfer it to a company to be hereafter formed for the purpose of relieving the present Company of the necessity of carrying on a business of local distribution. The Niagara Company has not yet announced its intention with respect to accepting or rejecting the franchise as amended.

The Power Stations at Hoboken, N.J.—The North Hudson County Railway Company, of Hoboken, N.J., operates about 83 miles of tramways, of which a considerable and increasing proportion is electrical. The power station for the electric cars is 200ft. long and 100ft. wide, and is in two storeys. There are two Corliss steam engines of 500 H.P. each, and three Ball engines of 250 H.P. each. The larger engines run at 65 revolutions, driving two General Electric multipolar dynamos. Each of the smaller engines drives two 125 H.P. Thomson-Houston dynamos. Steam is generated in six 125 H.P. boilers. It is an interesting point, however, and one which leads us to notice this tramway system now, that not only does it derive current from its own station, but, in addition, is so fitted as to be able to tap power from the mains of the Hudson Electric Light Company. In order to give some idea of the relative magnitude of the tramway power station and the electric light station, we may state that the latter includes the following plant:—There are two vertical cross-compound 500 H.P. Corliss engines, one horizontal cross-compound 1,500 H.P. engine of the same make, and one 650 H.P. cross-compound engine. About 190 electrically-driven cars are worked in all by the County Railway Company.

Power Vehicles on French Roads.—According to *Engineering*, in France, power vehicles, intended for use on ordinary roads, fall, on the one hand, under the regulations that control the use of steam boilers and engines, and, on the other, under the legislation which regulates the circulation of all classes of vehicles on roads and streets; thus, although there is no special legislation on the subject, the application of existing laws and police *ordonnances* are sufficient to provide against all probable dangers that might arise from the use of such vehicles. The special regulations apply only to Paris and the surrounding districts; but if, as appears probable, there is shortly to be a general increase in the use of such vehicles, legislation on the subject will become necessary. If it is found by experience

Digitized by Google

that the use of power carriages is not attended with inconvenience and danger to the ordinary pedestrian and to wheeled traffic, it is certain that a relaxation in the law will be permitted when expedient. Such an innovation in the means of locomotion may prove in the future, says our contemporary, to be of great value and convenience, but while it is in the experimental stage, it is only reasonable that the safety and convenience of the general public should be the first and principal consideration.

Reduction of Alumina by Carbon.—M. Moissan, says the *Engineering and Mining Journal* of New York, has shown that when crystals of corundum are heated in a carbon tube in the electric furnace metallic aluminium is obtained. At the high temperature of the electric furnace, produced by a current of 1,200 amperes at a pressure of 80 volts, the vapour of carbon is able to reduce the vapour of alumina. In another experiment 100 grammes of alumina were placed in a carbon tube (400mm. long by 40mm. internal diameter) closed at one end, and so arranged in the furnace that the closed end was raised to the highest temperature. On passing a current of 300 amperes at 65 volts for 15min., vapours were given off at the open end of the tube, which condensed on cold bodies, and proved, on examination, to be minute spheres of fused alumina. After cooling, the carbon tube was found to contain a white deposit of alumina, together with an ingot of alumina, while that portion of the tube which had been raised to the highest temperature contained a skin of graphite formed by the condensation of the vapour of carbon. On the walls of the tube were found small white or yellowish globules, consisting of a mixture of aluminum and its carbide. Starch, which supplies the carbon necessary for the reduction, may with advantage be mixed with the alumina before heating. Alumina may be melted in a carbon crucible without any reduction taking place, and it is only when the temperature is raised sufficiently high to vapourise both the alumina and the carbon that reduction is possible.

Proposed Light Electric Railway to the Peak District.—A large number of influential landowners and others in Derbyshire have been so long impressed with the great necessity for improved railway communication between Derby and Ashbourne that a proposal is now on foot for the construction of a light electric railway between those towns. Mr. John Shaw, jun., of Derby, with the assistance of Mr. Alfred Dickinson, has produced a scheme for the construction of this railway, and the proposal has already met with some favour. It is proposed that the line should be connected with the existing Derby tramway, which terminates on the Ashbourne-road, and thence it would run through the parishes of Mackworth, Kirk Langley, Brailsford, Ednaston, Osmaston, Compton, into the town of Ashbourne, terminating near Compton Bridge. On only one portion of the proposed line is there really a stiff grade, and that is for about one mile at the Asbourne end. It is suggested that the line should be laid on the western side of the high road, through nearly the whole length. Electric signalling would be adopted to enable the crossings to be placed at as great a distance as possible from one another. If the cars on the proposed railway are run at a maximum speed of 15 miles per hour the journey could be completed in an hour, thus showing a saving of time between the light railway and the ordinary railway on the North Stafford line. The gross rough estimate for the entire cost of the line is estimated at £62,300. The scheme has already received the sanction of a large public meeting of landowners and others, and a representative committee has been formed.

The Conductivity of Mixtures of Metallic Filings and Dielectric Substances.—In the *Comptes Rendus* for August 19th, M. G. T. Lhuillier contributes an account of some experiments made with mixtures of copper, aluminium or iron filings, and liquid and solid dielectric substances. His experiments go to show that the displacement of the filings in a liquid dielectric, or *vice versâ*, can be carried out without destroying the conductivity of the mixture, but also without producing it. These filings may be displaced in alcohol by means of a magnet; but the conductivity does not disappear, but is only slightly modified. Gentle tapping, on the other hand, completely annihilates the conductivity. Alcohol may be replaced by an equal volume of fresh alcohol without modifying the conductivity. A liquid dielectric may also be replaced by any other, provided the second has no chemical action on it, without the resistance of the mixture being affected. This is the case with water replacing olive oil. If, however, the second liquid dielectric can dissolve the first, as is the case with water taking the place of alcohol, the resistance, after remaining some time constant at 143 ohms, suddenly rose in one case in three or four minutes to about 500,000 ohms. This experiment, M. Lhuillier thinks, shows that if in the phenomena exhibited by these mixtures the dielectric plays an active part, it only does so through a very small distance. He thinks that each filing should be regarded as imprisoned in a sheath of liquid, which adheres by capillarity to the neighbouring sheath. The substitution of another liquid, identical or different, which has no dissolving action on the first, will thus leave the original equilibrium intact, and the conductivity will not be affected. The question then arises whether the dielectric becomes a conductor for short distances, and experiments by M. Lhuillier tend to show that it does not become conducting even at distances less than 1μ.

The Thunderstorm of August 22nd.—In a letter to *The Times* of Friday, Mr. G. J. Symons, writing from Camden-square, says :—

Lightning was, I believe, frequent from about 3 a.m., and thunder subsequently ; there is an irregularity in the Redier barograph trace at 4:30 a.m., which probably indicates a distant storm. Thunder was heard at 7:30, but I did not hear it until 15min. later, and I put the brontometer in action at 7:50. The storm was not a very bad one, the thunder being more noticeable than the lightning ; of the former there were 68 peals between 7:50 and 9:12 a.m. ; the rain began earlier in town than it did here, and was, I think, heavier, our total being about 0·05in., which fell in two little showers about 8:15 and 8:55 respectively. There was considerable barometric disturbance, but that cannot be clearly shown without a diagram. About twelve hours later a severe storm came on. My record begins at 7:52 p.m., with a distant storm in the S.W., but it was unimportant until 8 p.m., after which the storm became very heavy. I am sure that I missed the record of many flashes of lightning, and yet between 8 and 9 p.m. I have the times of 667, of which 111 are recorded between 8:15 and 8:20 p.m., 39 of them in the one minute from 8:16 to 8:17. The thunder was more continuous later; it was absolutely continuous from 8h. 26min. 50sec. to 8h. 28min. 30sec. (100 seconds), and, with two breaks amounting to perhaps 5sec., it was continuous from 8h. 26min. 50sec. to 8h. 29min. 55sec., or 3min. 5sec., I think an unusual duration in this country. The rain began at 8:23, and was over at 8:45, but it was heavy from 8:29 to 8:37, nearly all of the total 0·39in. falling in that time. There was a little hail from 8:35 to 8:40, but it was unimportant. The storm passed away to N.E.

The following are some of the fatalities and incidents that occurred :—An old gentleman named Gregson, aged 81, residing at Kingston, was watching the lightning from the window, and whilst standing there beside his wife he was struck, and expired almost immediately. Mrs. Gregson was unhurt.—A singular scene was witnessed at the Kingston Hotel. During the height of the storm it was crowded by people who had sought shelter, when a large ball of fire entered by the open door, and after shooting in a zigzag fashion through the bar, passed out of the door again. No damage was done.—The lightning caused the alarm bells of the Kingston and Surbiton Fire Brigade to ring continuously during the whole time the storm was raging.—Two large villas in Friern Park, North Finchley, were struck by lightning, and the roofs became ignited. —At Sandwich the spire of the Church of St. Bartholomew was struck by the lightning, and the tower was so shattered that it had to be taken down to prevent serious damage to the rest of the fabric. Some of the tiles had been hurled from the roof a distance of 120ft. from the building.—A young man named Ransome was struck by lightning, and killed, near Lancing College, Brighton.—Whilst the fishing smack "Albert," of Ramsgate, was at sea, the lightning struck the mast of the vessel, and the skipper, Mr. Alfred Wratten, who was standing just abaft, was instantly killed.—About half-past seven o'clock on Thursday night, a shepherd, employed by Mr. Thomas Peacock, of Willowrow Farm, near Littleport, was struck by lightning and killed.—A private of the 2nd Wilts Regiment is lying in a somewhat precarious state in the Cambridge Hospital, Aldershot, having received a great shock and severe burns under the arms and on the body. He was on guard on Thursday night, and during the storm sought shelter in the sentry-box. The rifle was twisted and doubled up.

ELECTROMAGNETIC THEORY.—LXXIII.*

BY OLIVER HEAVISIDE.

(*Continued from page 483.*)

§ 283. Start with the characteristic equation of a coil, being the form taken by the second circuital law when applied to a linear circuit of constant resistance. Say

$$e = (R + Lp)C, \qquad (2)$$

where R is the resistance and L the inductance of the circuit, C the current and e the impressed voltage.

First, let it be given that C is steady from the initial moment, and zero previously. What is the corresponding e? The answer is immediate. We want two impressed forces, namely, $e_1 = RC$ to keep up the current, and $e_2 = LpC$ to start it. Since $p1$ is a unit impulse, e_2 is an impulsive force of total LC. First we require the impulsive force establishing the momentum LC instantly, and then the steady force RC to keep it up against the resistance.

Now this is an example, not of the working of the expansion theorem, but of its failure. But the treatment is sufficiently clear without it. If we tried to force it into the expansion theorem we should want the root of $(R + Lp)^{-1} = 0$, which has no finite root.

But now find the C due to steady e, which is quite a different problem. By (2) the answer is

$$C = \frac{e}{R + Lp}, \qquad (3)$$

which is of a proper form for the expansion theorem. Here Z_0 is R; p is $-R/L$; dZ/dp is L; so, by (1),

$$C = \frac{e}{R} + \frac{\epsilon^{-Rt/L}}{(-R/L)L} = \frac{e}{R}(1 - \epsilon^{-Rt/L}), \qquad (4)$$

showing the gradual rise of C to its steady value.

Since this case is fundamental, the operational way of getting the result may also be indicated. We have

$$\frac{e}{R + Lp} = \frac{e}{Lp(1 + R/Lp)} = \frac{1}{R}\left\{\frac{R}{Lp} - \left(\frac{R}{Lp}\right)^2 + \left(\frac{R}{Lp}\right)^3 - \dots\right\}e. \ (5)$$

This is got by expanding the fraction by division. The rest is done by

$$p^{-n}1 = \frac{t^n}{\lfloor n}, \qquad (6)$$

which makes, applied to (5),

$$C = \frac{e}{R}\left\{\frac{Rt}{L} - \frac{1}{\lfloor 2}\left(\frac{Rt}{L}\right)^2 + \frac{1}{\lfloor 3}\left(\frac{Rt}{L}\right)^3 - \dots\right\}, \qquad (7)$$

which is the expansion of (4), by the meaning of the exponential function. The steps (5) and (7) to obtain (4) may look cumbrous. But there is deception here, for it is, perhaps, a shorter and more direct way than any other. The deception comes in in the customary use of the short expression of the exponential function to denote a certain infinite series, and in taking its properties for granted. However, once done, of course there is no further need for the intermediate work. It will be observed that the case is that of equation (3), § 265, slightly modified. To obtain it as in the equation referred to, let e be impulsive, say $= pE$, where E is the impulse total. Then equation (3) above makes

$$C = \frac{pE}{R + Lp} = \frac{E}{L(1 + R/Lp)} = \frac{E}{L}\epsilon^{-Rt/L}, \qquad (8)$$

as in (3), § 265. The impulse E produces the equivalent momentum E = LC. There is no impressed voltage to keep it up, so it decays according to (8).

In doing (8) by the expansion theorem, notice that $p = 0$ makes C = 0, so there is no steady term. The rest is as in equation (4), only multiplying by p or $-R/L$. Thus, by (1),

$$C = \frac{pE}{R + Lp} = E\frac{p\epsilon^{pt}}{pL} = \frac{E}{L}\epsilon^{pt}, \qquad (9)$$

where p has the special value which makes $R + Lp = 0$.

Next consider another fundamental case, that of a leaky condenser; that is, a conducting leyden or condenser, or one made conducting (equivalently) by a shunt. We have

$$C = (K + Sp)e, \qquad (10)$$

where K is the conductance and S the permittance. The form is the same as for a coil, but current and voltage are interchanged, as well as conductance and resistance, and inductance and permittance.

In order that the voltage e should be instantly raised from zero to constancy, and maintained constant, we require the steady current Ke, and an initial impulsive current of total Se; that is, first the charge Se must be impulsively established, and then it must be maintained constant by the steady current Ke, which goes through the shunt K, of course. Without the steady current the charge of the condenser would disappear.

Now invert the problem. Say

$$e = \frac{C}{K + Sp}, \qquad (11)$$

and inquire what e is required to make C jump from zero to constancy. Here the expansion theorem applies. It is like equation (3) above. So

$$e = \frac{C}{K}(1 - \epsilon^{-Kt/S}) \qquad (12)$$

answers the question, either by translation of symbols or independently.

In another form, if the voltage be made to rise from zero to constancy in the way indicated by (12), the current will be constant, viz., C, during the whole time. This current is *the* current, the total current in the condenser and shunt. The part in the shunt is Ke; the rest is in the condenser. For convenience we assume that the conductance is supplied externally.

§ 284. As regards the simply periodic solutions in these cases, the working is perfectly simple, by means of the property $p^2 = -n^2$ which obtains in simply periodic states, or, which is the same, $p = ni$, applied to reduce the resistance or conductance operator to the standard form $a + bp$. The case

$$e = (R + Lp)C, \qquad (13)$$

when it is C that is given as a simply periodic function, say, $C = c \sin(nt + \theta)$, is obvious, for (13) is in the standard form already.

In the other case, when e is given instead of C, we have

$$C = \frac{e}{R + Lp} = \frac{(R - Lp)e}{R^2 + L^2n^2}. \qquad (14)$$

That is, we bring C to the standard form by multiplying the numerator and denominator by the operator conjugate to $R + Lp$, that is $(R - Lp)$. This realises the denominator. Whether this is done by $p^2 = -n^2$, or by $p = ni$, is indifferent. Only, it should be noted that i is not the imaginary of algebra, but, as I have pointed out before, the differentiator $d/d(nt)$; that is, p/n. It is a specialised differentiator, which may be treated like the imaginary because $p^2 = -n^2$ in simply periodic cases. But it must be finally interpreted correctly, as a differentiator, of course. There is sometimes, perhaps often, some confusion or indistinctness of ideas on this point.

Another point which may not be always understood is the assumption involved that both operand and resultant are simply periodic. This is essential. But it by no means follows that a simply periodic e produces a simply periodic C. It does practically, because there is resistance. But if it be given that there is no resistance, so that $e = LpC$; then if e is given, we obtain, by $p = ni$,

$$C = \frac{e}{Lp} = -\frac{pe}{Ln^2}. \qquad (15)$$

This is the solution *if* C is simply periodic, as well as e. But it would never reach this state without resistance. That is, given a little resistance, e would, in a long time, lead to the state (15) approximately; but if $e = LpC$ is rigidly true, and e starts when $t = 0$, the resulting C is, if $e = e_0 \sin nt$,

$$C = \frac{e_0 \sin nt}{Lp} = \frac{e_0}{Ln}(1 - \cos nt), \qquad (16)$$

* This series of articles is a portion of Vol. II. of Mr. Heaviside's work on "Electromagnetic Theory." All rights of reproduction are reserved.

Digitized by Google

which is quite different. Here, of course, the reciprocal of p signifies integration from 0 to t.

We may easily show the complete establishment of the simply periodic state from (5), by taking $e = e_0 \sin nt$, but *not* assuming C to be simply periodic. Then the powers of p^{-1} are successive integrations from 0 to t; and the result is

$$C = \frac{e_0}{R}\left\{\frac{R}{Ln}(1-\cos nt) - \left(\frac{R}{Ln}\right)^2(nt - \sin nt)\right. \qquad (17)$$

$$\left. + \left(\frac{R}{Ln}\right)^3\left(\frac{(nt)^2}{\underline{|2}} - 1 + \cos nt\right) - \left(\frac{R}{Ln}\right)^4\left(\frac{(nt)^3}{\underline{|3}} - nt + \sin nt\right) + \dots\right\},$$

where the functions of t in the brackets are the successive integrals of $\sin nt$, which are obtainable at sight, or verifiable by differentiation.

By collection of terms, (17) may be put in the form

$$C = \frac{R \sin nt - Ln \cos nt}{R^2 + L^2n^2} + \frac{Ln\epsilon^{-Rt/L}}{R^2 + L^2n^2}. \qquad (18)$$

Here the second part cancels the first initially, though it ultimately vanishes and leaves the first in full play. But when R is zero we never arrive at the simply periodic state, but have the state (16) instead, which is the beginning part of (17), independent of R. As regards the establishment of (18), however, it is quite sufficient to first write down the final periodic state, and then add on a term to cancel it initially and subside at the proper rate. The above way of successive integration shows the internal working.

That p specialises itself to ni when there is simple periodicity of e and C rests upon $p^2 = -n^2$. That the transformation used in (14) is fully valid without escape may be seen thus:— Operate on (13), which is general, by $R - Lp$, making

$$(R - Lp)e = (R^2 - L^2p^2)C, \qquad (19)$$

which is also general. Now specialise, by letting C be simply periodic, and therefore, by (13), e also, though the converse is not necessarily true. We now have $p^2C = -n^2C$, and (19) becomes

$$(R - Lp)e = (R^2 + L^2n^2)C, \qquad (20)$$

which is (14) slightly changed in form.

In the case of a complicated operational solution, if we choose to clear it of fractions, we can generally bring it to the usual form of a differential equation, say

$$Ae = BC, \qquad (21)$$

where A and B are operators involving only direct operations —that is, integral positive powers of p. Then, by specialising e and C to be simply periodic, we make the power of p^n be constant when n is even, and be $p \times$ constant when odd. So we reduce (21) to the form

$$(A_1 + A_2p)e = (B_1 + B_2p)C, \qquad (22)$$

where the A's and B's are constants. A similar treatment applies in the case of irrational operators, as regards their reduction to the standard form.

Finally, if want e in terms of C, multiply by $A_1 - A_2p$. If C in terms of e, then by $B_1 - B_2p$ instead. This work is just as well, and it may be much better done in the operational solution itself, without preliminary conversion to the usual stretched-out form of a differential equation, by either $p^2 = -n^2$ or $p = ni$. Of course, the structure of the formulæ is plainer and simpler in the operational form. This is a very important matter, especially to the electrician, as he can use electrical ideas throughout rather than purely mathematical.

§ 285. In the above cases of a coil or of a condenser, there is but one degree of freedom. To make two, we may put the coil and condenser in sequence. The resistance operators are additive, so

$$e = \left(R + Lp + \frac{1}{K + Sp}\right)C \qquad (23)$$

is the equation of voltage, e being impressed on the complete arrangement. We need say nothing here about the simply periodic case. By inspection of (23) we see that the operator is peculiar, as the expansion theorem applies to one part of it, though not to the other. If C is zero before, and steady after the initial moment, we see that the corresponding e consists of three parts, namely, an impulsive voltage of total LC to generate the current instantly; a steady voltage RC to keep it up against R; and the variable voltage

$$\frac{C}{K}(1 - \epsilon^{-Kt/S}). \qquad (24)$$

The impulsive voltage, and the steady $C(R + K^{-1})$ are clear enough. The exponential term is required to keep the total current constant in the condenser and shunt. The initial impulse does nothing to the condenser. It is merely operative on the coil.

The case $K = 0$ is interesting. Then, by (24), or much more simply by (23), the voltage on the condenser is Ct/S, increasing uniformly with the time.

Only one root is concerned in the above. But if we inquire into the C produced by a steady e, then two roots come into play. Thus, by (23),

$$C = \frac{e}{R + Lp + (K + Sp)^{-1}}. \qquad (26)$$

Taking the denominator to be Z, and applying the expansion theorem, equation (1), we see first that Z_0 is $R + K^{-1}$, and next that

$$p\frac{dZ}{dp} = Lp - \frac{Sp}{(K + Sp)^2}. \qquad (27)$$

So, if p_1 and p_2 denote the two roots of $Z = 0$, the expansion of C is

$$C = \frac{e}{R + K^{-1}} + \frac{e\epsilon^{p_1t}}{Lp_1 - Sp_1(R + Lp_1)^2} + \frac{e\epsilon^{p_2t}}{Lp_2 - Sp_2(R + Lp_2)^2}, \qquad (28)$$

where, instead of $(K + Sp)^{-2}$, we have written $(R + Lp)^2$, because $Z = 0$ makes them equal. Into a discussion of (28) in detail it is unnecessary to enter, the object here being merely the application of the expansion theorem. The theory of circuits in detail would need a chapter to itself.

Another way is to convert (26) to

$$C = \frac{(K + Sp)e}{(R + Lp)(K + Sp) + 1}. \qquad (29)$$

This will give the same result by the expansion theorem, first as regards the steady state, and next as regards the terms variable with the time. In the numerator, p has to receive the two values in succession which make the denominator vanish; that is, if $C = (Y/Z)e$, and the subsidence constants of the normal systems depend upon the vanishing of Z, then

$$C = \frac{Y_0}{Z_0}e + e\Sigma\frac{Y\epsilon^{pt}}{p\dfrac{dZ}{dp}} \qquad (30)$$

expresses the expansion theorem, being equivalent to equation (1). That is, putting it in another form, it is on the infinities of Y/Z that the terms involving the time depend.

In (14), with the specialised meaning of p, the algebrisation was effected by introducing a common factor into the numerator and denominator. Comparing (29) with (26), we see that a common factor is also introduced, though unnecessarily. It does not alter the roots of the denominator. Suppose, however, that it did. Suppose, for instance, we multiply numerator and denominator in (26) by $r + lp$, thus introducing a fresh root $p = -r/l$ to the modified Z. It will make no difference in the working of the expansion theorem. The new term is of size zero, and is, therefore, automatically excluded.

There is an important principle involved here, which may be referred to in passing. Let $C = e/Z$ be the operational solution of an electromagnetic problem, say, involving a complicated combination of coils and condensers. If $Z = 0$ has m roots, there are m degrees of freedom, and m terms in the C expansion, besides possibly an outside steady term. Now, by introducing special relations amongst the resistances, inductances, &c., concerned in Z, we may be able to reduce it to a simpler form, involving a smaller number of roots, even down to one root, it may be. This means that the combination behaves, towards the impressed force, under the circumstances, just as though it were some simpler combination. So far as the expansion of $C = e/Z$ goes, there is no loss of generality by the simplification of Z mentioned. The reduced form used in

Digitized by Google

the expansion theorem will give the proper result. The same applies to simply periodic solutions. Nevertheless, the combination does possess a greater generality than the simplified equivalent in other respects, as regards a differently situated impressed force for instance, or as regards free subsidence from an arbitrarily given initial state. It is very convenient to be able to eliminate simply the unessential and inoperative parts of the work, and the Z operators allow us to do this.

We also see, by reversing the reasoning, that when we alter $C = e/Z$ to $C = Ye/YZ$, and introduce thereby a number of new roots of the denominator, viz., those (if any) of $Y = 0$, we are really enlarging the problem, for YZ belongs to a larger combination. But then it is done in such a way that the larger combination is equivalent, as regards the relation between e and C, to the smaller. The extra terms in the expansion of C are of zero size. Thus, with unit operand,

$$\frac{1}{Z} = \frac{Y}{YZ} = \frac{Y_0}{Y_0 Z_0} + \Sigma \frac{Y \epsilon^{pt}}{p(ZY' + YZ')}, \qquad (31)$$

where the accent means differentiation to p. Now, with the roots of $Y = 0$ only, the vanishing numerators make the terms be zero; but this does not happen with those of $Z = 0$. We therefore get the original form of equation (1).

Returning to the condenser and coil, put them in parallel, and subject them to the same impressed force. The conductance operators are now additive, and therefore

$$C = \{(K + Sp) + (R + Lp)^{-1}\}e \qquad (32)$$

is the equation of current.

To have e steady after the initial moment, we require an impulsive current of total Se, a steady current Ke, and a gradually rising current

$$\frac{e}{R}(1 - \epsilon^{-Rt/L}),$$

by what has preceded. Only one time function is concerned.

On the other hand, if the current is steady after the initial moment, we have to expand

$$e = \frac{C}{(K + Sp) + (R + Lp)^{-1}}. \qquad (33)$$

Comparing with (26), and its expansion, we see that the result in the present case is

$$e = \frac{C}{K + R^{-1}} + \frac{C\epsilon^{p_1 t}}{p_1 S - p_1(K + Sp_1)^2} + \frac{C\epsilon^{p_2 t}}{p_2 S - p_2(K + Sp_2)^2} \qquad (34)$$

The roots p_1, p_2, are as before, in (28).

§ 286. As another example of two degrees of freedom, consider two linear conductive circuits. The second circuital law applied to them makes

$$E = (R + Lp)C + Mpc, \qquad (35)$$

$$e = (r + lp)c + MpC, \qquad (36)$$

using big letters for one circuit, small for the other, except in the case of M, the mutual inductance, which is common to both. This is ironless mathematics, of course. Young investigators need not be discouraged by the contempt which is too often poured upon ironless mathematics in engineering journals. It is fundamental, and very useful. Sometimes the contemners only indicate their own ignorance.

If both C and c are to suddenly become steady, we require the voltages indicated explicitly, viz., the steady RC in one and rc in the other circuit, following the initial impulses $LC + Mc$ and $lc + MC$ respectively.

If c is to be kept zero, put $c = 0$, making

$$E = (R + Lp)C, \qquad e = MpC. \qquad (37)$$

That is, we require the voltage MpC in the second circuit to prevent current in it. At the same time, the equation and behaviour of the first circuit are the same as if the second were taken away. The principle of the destruction of mutual induction by a suitable impressed force is a useful one in theoretical reasoning.

When, on the other hand, the forces are given, we should solve for the currents. Thus, by cross multiplication, we may eliminate C or c in turn. The equation of C is

$$C = \frac{(r + lp)E - Mpe}{(R + Lp)(r + lp) - M^2 p^2}, \qquad (38)$$

which, by (1), or (30) more conveniently, expands to

$$C = \frac{E}{R} + \frac{E(r + lp_1) - Mp_1 e}{Lp_1(r + lp_1) + lp_1(R + lp_1) - 2M^2 p_1^2}\epsilon^{p_1 t} \qquad (39)$$
$$+ \text{ditto with } p_2.$$

Here p_1 and p_2 are the roots of the denominator in (38).

The above examples, going only as far as two degrees of freedom, are sufficient to show how the expansion theorem is to be applied. They are not particularly good examples, but are chosen rather to show how to readily discriminate different operators, and see when the expansion theorem applies, and when it does not.

(To be continued.)

THE SELF-INDUCTION OF ARMOURED MAINS.

BY J. WHITCHER.

Mains protected with a surrounding of iron, either as a separate tube or as a lapping of wire or tape, fill the principal part in modern methods of electrical distribution, and without doubt they will continue to do so. Single conductors, or compound conductors in which the flow and return of current do not balance, protected in this way, are open to the objection, when used for alternating currents, that there is a more or less serious amount of inductive drop due to the iron. Concentric cables and conductors run in complete pairs or sets in one pipe are not, of course, subject to this disqualification, but it is sometimes a great practical convenience to be able to use single conductors. Particularly is this the case with a three-wire system of distribution. Moreover, concentric mains, especially if triple, are costly and cumbrous, and a pipe to take three heavy distributing cables must be excessively large, meaning expensive and troublesome service boxes.

It is of some importance, therefore, to know to what extent it is safe to ignore the inductive effects of the iron, and to this end it is necessary to determine the numerical dimensions of the drop occasioned thereby. The following is a brief statement of the theory of the extra self-induction of conductors, due to iron armourings or surroundings, leading to some useful practical formulæ and approximations :—

Taking firstly the case of a conductor in an iron tube, we have to determine the extra induction around the conductor caused by the presence of the iron, and its reactive effect, or the amount of counter E.M.F. it will set up in the conductor.

Put I = the nominal current in the conductor;
n = the frequency;
$B_{\prime\prime}$ = the maximum value of the induction in the iron or the magnetic flux per square inch;
μ = the permeability of the iron;
d = the mean diameter of the tube in inches;
t = the thickness " " ";
e = the E.M.F. of self-induction—the effective mean value.

We must assume that the current variations are according to the simple sine law, this being near enough to the average condition of things in practice; also that the effective mean value of e will be equivalent to that it would have if it varied after the same law. In this case the maximum value of the current will be $\sqrt{2}\,I$ and the effective mean value of e will be equal to 1·1 times the true mean.

Then, if there be no secondary or eddy currents created, the maximum magnetic flux in the iron per square inch of its area will be

$$B_{\prime\prime} = 1{\cdot}016\pi I \times \frac{\sqrt{2}\mu}{\pi d} = 1{\cdot}437\frac{I}{d}\mu. \quad . \quad . \quad (1)$$

The extra E.M.F. of self-induction due to the iron will be that produced by this flux cutting the conductor $4n$ times per second, since it changes from its positive to its negative maximum and back again in every alternation. This gives the true mean value of e; the effective value is therefore

$$e = 1{\cdot}1 \times 1{\cdot}437\frac{I}{d}\mu \times 4n \times 10^{-8} \text{ volts}$$
$$= 6{\cdot}321\frac{I}{d}\mu n \times 10^{-8}.$$

Digitized by Google

This per square inch section of iron, which is equivalent to $1/t$ inches length of conductor. Therefore per 100ft. of conductor

$$e = 1{,}200\, t \times 6{\cdot}321\, \frac{I\, n}{d}\, \mu \times 10^{-8} = 0{\cdot}000076\, \frac{t}{d}\, I\, n\, \mu. \quad (2)$$

This E.M.F. is not exactly a counter force, but only so in degree. Instead of being opposite to, or 180deg. of phase behind the magnetising current, it is but 90deg. It must therefore be compounded with the prime electromotive force on the circuit by means of the parallelogram of forces. Thus putting E the E.M.F. impressed on the circuit and E_1 the effective E.M.F. at the far end, the total drop will be, of course, $= E - E_1$. Put D = the resistance drop, then the net drop due to self-induction is $E - E_1 - D$. By the parallelogram of forces $E_1 + D$ is the resultant of E and e; and e is in quadrature to $E_1 + D$. Therefore $E_1 + D = \sqrt{E^2 - e^2}$; and the total drop is equal to $E - \sqrt{E^2 - e^2} + D$. The diagram given later on will put this more clearly.

It may be observed that e may be rather large without producing an appreciable drop. Its chief effect is to make the current lag behind the impressed force E; and until it causes the angle of lag to be considerable its effect as drop is not very marked. Thus, for instance, if e be 10 per cent. of E, and D 2 per cent., the total drop will be only 2·66 per cent.

It is needless to pursue this simple case further, as it is only of theoretical interest. It is impossible but that there should be considerable eddy currents set up in the mass of iron, so that in practice the results will be largely modified by them. The effect of eddy currents will be to reduce the induction in the iron, and therefore e; yet it will increase the actual drop, as e is brought thereby into a greater degree of oppositeness to E.

To determine the influence of these eddy currents, we may consider them as equivalent to one current flowing longitudinally along the inner layers of the pipe and returning along the outer layers. It is clear that the resistance to this current will be equal to four times the longitudinal resistance of the pipe. Also that the equivalent current will be that due to one-half the E.M.F. impressed on the outermost circuit possible within the iron. For the E.M.F. producing the eddy current in any circuit marked out on any given longitudinal section of the tube wall, being due to the induction through the circuit, will evidently be greatest when the circuit is taken around the outer boundaries of the section, and therefore enclosing all the iron. And it will grade down regularly for circuits taken within this one, until it becomes *nil* at the centre line of the section. Thus the average E.M.F. on the whole section will be one-half that on the outermost circuit. Now the latter is actually the E.M.F. of self-induction in the conductor due to the iron, for it is generated by the alternations of the same magnetic flux.

Therefore, if ρ be the specific resistance of the iron in ohms per 100ft. of 1 sq. in. section, the resistance of the eddy current circuit in the same length of pipe will be $\frac{4\rho}{\pi t d}$. And the mean effective eddy current will be

$$i = \frac{e}{2} \cdot \frac{\pi t d}{4 \rho} = 0{\cdot}39\, \frac{e\, t\, d}{\rho}. \quad (4)$$

This current is necessarily in quadrature with the magnetising effect of the currents acting, *i.e.*, the prime current I and itself. The magnetising component is, therefore, the resultant of the two and equal to $\sqrt{I^2 - i^2}$. Substituting this for I we have :—

$$e = 0{\cdot}000076\, \frac{t}{d}\, n\, \mu \sqrt{I^2 - i^2} = \frac{0{\cdot}000076\, t\, n\, \rho\, \mu\, I}{d \sqrt{\rho^2 + (0{\cdot}00003\, \mu\, n\, t^2)^2}}. \quad (5)$$

To know μ it is necessary to know B; hence it is more convenient to write

$$e = 0{\cdot}000053\, t\, n\, B \left(\text{or } 2{\cdot}5\, \frac{P\, i}{t\, d}\right). \quad (6)$$

$$B = \frac{1{\cdot}437\, \mu\, \rho\, I}{d \sqrt{\rho^2 + (0{\cdot}00003\, \mu\, n\, t^2)^2}} \left(\text{or } 48{,}000\, \frac{P\, i}{n\, d\, t^2}\right). \quad (7)$$

Also $$i = \frac{0{\cdot}00003\, n\, t^2\, \mu\, I}{\sqrt{\rho^2 + (0{\cdot}00003\, \mu\, n\, t^2)^2}}. \quad (8)$$

These equations are unwieldy to handle, because of the difficulty of assigning values to μ. But taking a practical view of them, it becomes clear that the exact value of μ between limits is not of much consequence. Thus for every practical case it makes little difference whether μ is 1,000 or infinity; and for many μ may be anything over 50 or 100 without greatly affecting the results. In the tables given herewith, values for

Digitized by Google

e and i are calculated for mains run in cast-iron pipes taking μ as 250, and also as infinity. For wrought-iron pipes minimum values are shown for $\mu=100$, and maximum values taking it infinity. The true value must be within this range, which it will be seen is sufficiently narrow for most purposes.

For wrought iron this range includes all values of the magnetising force, from the highest to the lowest; for Ewing shows that for the lowest inductions observed μ tended to a minimum of 183 for a specimen of soft iron, and 81 for hard. The case of cast-iron is not so definite. To keep the range narrow, the lower limit of μ is set at 250, which is doubtless too high to take in low or high inductions. But there are no determinations of the permeability of cast-iron at low inductions; and probably it varies greatly with different specimens. Hence it is not well to put it lower, since for thin cast tubes the results vary much for varying values of μ.

The specific resistance ρ has an important influence; and it varies considerably, over a range of about 100 per cent. for wrought, and an indefinite and undetermined one for cast iron. Hopkinson has put the resistance of cast-iron at ten times that of wrought. Therefore, putting for wrought $\rho=0{\cdot}005$, and for cast $\rho=0{\cdot}05$, the formulæ reduce thus for given values:—

For cast iron, when $\mu=250$ and ∞,

$$e=0{\cdot}125\,\frac{i}{d\,t} \qquad \text{and} \qquad 0{\cdot}125\,\frac{I}{dt} \quad . \quad (9)$$

$$i=\frac{0{\cdot}15\,n\,t^2\,I}{\sqrt{1+(0{\cdot}15\,n\,t^2)^2}} \qquad \text{and} \qquad I \quad . \; . \; . \quad (10)$$

For wrought iron, when $\mu=100$ and ∞,

$$e=0{\cdot}0125\,\frac{i}{d\,t} \qquad \text{and} \qquad 0{\cdot}0125\,\frac{I}{dt} \quad . \quad (11)$$

$$i=\frac{0{\cdot}6\,n\,t^2\,I}{\sqrt{1+(0{\cdot}6\,n\,t^2)^2}} \qquad \text{and} \qquad I \quad . \; . \; . \quad (12)$$

To note the full significance of these results we must have some idea of the phase relations of I and i. The clock-

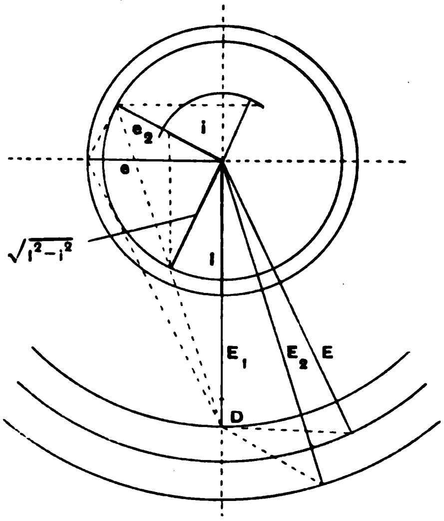

Fig. 1.

face diagram (Fig. 1) illustrates this. Two cases are shown, the one ignoring eddy currents, as already described, and the other taking them into account. The thick lines represent currents, the thin ones electromotive forces. For the first case E_1+D is shown as the resultant of E and e, the current I being the only one acting. For the second case the current i disturbs the influence of I so that the magnetising force is due to their resultant, the line $\sqrt{I^2-i^2}$. Hence E_1+D is now the resultant of E_2 and e_2. By the construction we have the total drop

$$E_2-E_1=E_2+D+e_2\frac{i}{I}-\sqrt{E_2{}^2-e_2{}^2+e_2{}^2\frac{i^2}{I^2}}. \quad . \; . \quad (13)$$

When i is approximately equal to I, which happens when the pipe is thick or of high permeability, this reduces to

$$E_2-E_1=D+e_2,$$

meaning that e_2 is opposite in phase to E_2, and therefore wholly effective as drop; and when E_2 is large compared with the drop, which is generally the case, we have very approximately

$$E_2-E_1=D+e_2\,\frac{i}{I}. \quad . \; . \; . \; . \; . \quad (14)$$

Accepting these simple and practical approximations, we have the inductive drop in forms independent of the E.M.F. on the conductor, and therefore it is possible to tabulate results.

There will be a certain amount of loss due to hysteresis in the iron, but it is difficult to account for it in a practical manner. However, B is most generally low, as may be seen by working out formula (7), assuming $\mu=\infty$, which gives for cast iron $B=\frac{2{,}400\,I}{n\,d\,t^2}$, its highest possible value. The hysteresis loss cannot therefore be very significant. Its effect is very similar to that which would result from an increase in the specific resistance of the iron.

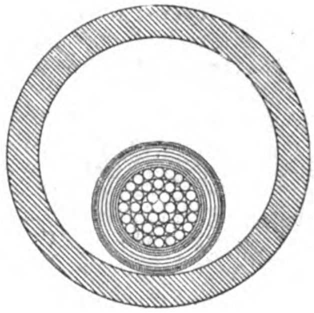

Fig. 2.

It is of more relative prominence in the case of thin metal. To estimate its amount, assuming it not to affect the self-induction, get the loss in watts from the weight of the pipe and the hysteresis per lb. at the given induction. From this the equivalent drop can be found. Take the hysteresis of the wrought at twice, and that of the cast at six times the tabulated values for soft iron.

As a practical example of the foregoing, take a conductor, carrying, say, 200 amperes at 100 volts, run in a cast-iron pipe of $2\frac{1}{2}$in. inside diameter, as shown in cross-section in Fig. 2. The weight of this pipe, including faucet, would be about $9\frac{1}{2}$lb.

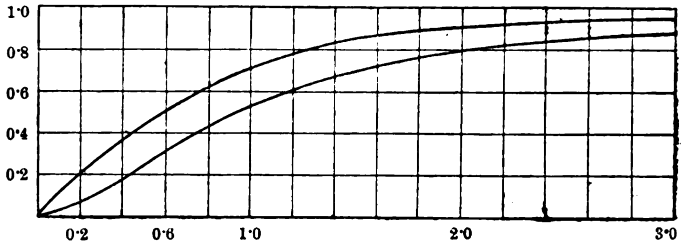

Fig. 3.

Upper Curve=Sine-Tangent, or $y=\frac{x}{\sqrt{1-x^2}}$,

Lower Curve=(Sine)²-Tangent, or $y=\frac{x^2}{1+x^2}$,

where $x=0{\cdot}006\,\mu\,n\,t^2$ for wrought iron, and $0{\cdot}0006\,\mu\,n\,t^2$ for cast iron.

per foot, giving an average thickness of $\frac{5}{16}$in. The mean diameter d is therefore $2\frac{13}{16}$in.

From (9) and (10) we have, per 100ft. run, when $\mu=50$

$e=8$ volts, $\quad i=53$ amperes,

$e\frac{i}{I}=2{\cdot}15$ volts, $\quad B=4{,}000$ per square inch;

when $\mu=250$

$e=25$ volts, $\quad i=166$ amperes,

$e\frac{i}{I}=21$ volts, $\quad B=14{,}000$;

when $\mu=\infty$,

$e=30$ volts, $\quad i=200$ amperes, $\quad B=17{,}400$.

The true drops for the first two cases as calculated by (13) are 2·45 and 22 volts, so that the approximation $e\,i/I$ gives 12 per cent. and $4\frac{1}{2}$ per cent. errors.

Digitized by Google

The range between the maximum and minimum chosen values is only about 30 per cent. For practical purposes it suffices to take their mean, which in the above is roughly 26 volts.

This case is impractical, of course, but it is of interest to note that the hysteresis loss would be something like 1,400 watts, meaning 7 volts.

A very useful form of main for street work is that armoured with two crossing lappings of steel tape. Magnetically this armour may be regarded as a single closed tube of thickness equal to the gauge of the tape. Granting this, its effect may be calculated as that of a tube, but it will be noticed that the influence of μ is much more important in small thicknesses like these. The curves given in Fig. 3 will facilitate an understanding on this point. The upper one represents the variation of e in relation to either μ or n when one or the other is constant. It also represents i for varying values either of μ, n, or t. The lower curve represents $e\frac{i}{I}$ relative to μ or n. The former is a "sine tangent" curve; the latter is a "sine squared tangent."

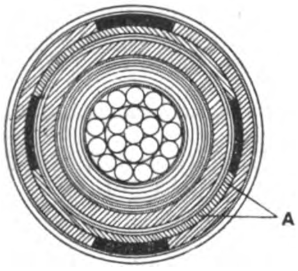

Fig. 4.

For pipes thicker than $\frac{1}{4}$in. if cast iron, and $\frac{1}{8}$in. if wrought, the possible values will lie on the curve somewhere to the right of the ordinate 2. For thinner tubes, and particularly armour, they will lie most probably to the left. Hence near approximations are impossible. In Table III. are given maximum and minimum values for armour of four different gauges, the maxima being for $\mu = 1{,}000$, which is never likely to be attained, and minima $\mu = 50$. These, of course, are the resultant permeabilities of the iron and air-gaps.

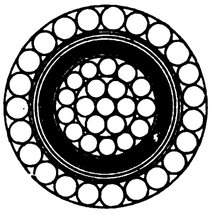

Fig. 5.

Fig. 4 is a typical instance of this class of armouring, representing a 19/12 cable, lead covered and armoured with four steel tapes of 16 S.W.G. in two layers. From Table III its higher limit is $0{\cdot}16\frac{I}{d} = 0{\cdot}15\,I$, or 15 volts per 100ft. run, if $I = 100$ amperes at 100 frequency; and its lower limit $0{\cdot}003\frac{I}{d} = 0{\cdot}0027\,I$, or 0·27 volts. This is a long range, and practically the mean is half the higher value, or $7\frac{1}{2}$ volts. Probably this is too large, but in lieu of actual determination by experiment it would be safe to take it thus.

Another class of armoured cable is shown in Fig. 5, which represents a 19/12 cable armoured with 24 10 S.W.G. galvanised iron wires—rather a heavier armouring than usual. It is difficult to estimate the reluctance of the ring of iron cylinders that make up the magnetic circuit; but probably Prof. S. P. Thompson's formula for the reluctance between cylindrical magnet limbs will give a fair approach to the reluctance between each adjacent pair of semicylindrical faces. This is per inch length of limb,

$$R = \frac{0{\cdot}4}{\pi}\log_e \frac{1}{x + 1 - \sqrt{x^2 - 2\,a\,x}},$$

where x is the ratio between the distance between the cylinders, and their diameter. If there are N wires the total reluctance is N R. The reluctance of the ring of air displaced would be $= N$. The value of R for any probable case will be between 0·1 and 0·2, for the distance separating the wires is a film of zinc and air, and assuming this to be 0·01in., and an average diameter of wire to be 0·1in., then $R = 0{\cdot}068$, the ratio x being $= 0{\cdot}1$. Also if $x = 0{\cdot}05$, $R = 0{\cdot}044$.

Working out formula for e we have

$$e = \frac{0{\cdot}00024\,I\,n\,t}{N\sqrt{R^2 + (0{\cdot}00048\,n\,t^3)^2}},$$

from which it is clear that for the usual values of t the last term in the surd is negligible, meaning that the eddy current effect is inconsiderable. Hence

$$e = 0{\cdot}00024\frac{I\,n\,t}{N\,R} = 0{\cdot}000076\frac{I\,n\,t^2}{d\,R} = 0{\cdot}0015\,I\,n\frac{t^2}{d},$$

taking $R = 0{\cdot}05$ as a fair average.

Evidently this is of very small account in practice. The actual inductive drop, it should be observed, per 100ft. run is $E - \sqrt{E^2 - e^2}$, as in the simple case first given.

THE LOCALISATION OF EARTH FAULTS ON ELECTRIC LIGHT CIRCUITS.

BY J. PIGG.

If the two mains supplying an electric light network are connected by a suitable resistance, the middle point of which is connected to earth through a galvanometer, the latter will not be affected so long as the insulation resistance remains perfect.

If an earth fault exists on either main, in the distributing network or in the dynamo circuits, the galvanometer will show a deflection, and the direction of the deflection will depend whether the fault exists on the + or − side. Further, the amplitude of the deflection will be a measure of the magnitude of the fault which it indicates.

If we move the point of connection with the galvanometer along the resistance towards the faulty cable, we will find the magnitude of the deflection decrease, and when the fault exists on the main, or in the distributing network, a point will be found at which the potential at the point of connection on the resistance will be balanced by the potential at the fault, and there will be no deflection of the galvanometer. In this case the fall of potential through the artificial circuit to the point of connection with the galvanometer and earth is exactly the same as that down the leaky main to the fault.

Let E = Difference of potential at point of test;
E_1 = Difference of potential at distributing point;
R = Resistance of artificial circuit;
R_1 = Resistance of lighting circuit at time of test;
C = Current in lighting circuit at time of test;
c = Current in artificial circuit;
r = Resistance between the leaky main and the galvanometer connection on the artificial circuit when balance is obtained;
r' = Resistance between point of test and the position of fault of main.

Then $\frac{E}{R} = c$ and $\frac{E}{R_1} = C$;

also $cr = Cr_1$,

from which $r_1 = \frac{r\,R_1}{R}$;

but $R_1 = \frac{E}{C}$ at the time of test.

$\therefore\quad r_1 = \frac{r\,E}{R\,C}.$

From this equation we obtain the resistance between the point at which the test is made, and the point at which the fault exists, in terms of the resistances of the artificial circuit,

Digitized by Google

the difference of potential at the point of test and the lighting current, all of which quantities are easily obtained.

Let r_2 = the resistance of each of the two mains under test.

Then if $r_1 < r_2$,

the fault exists on the main between the point of test and the distributing point. When this is the case we have, since the resistance of the main is practically uniform throughout its length,

$$\frac{x}{L} = \frac{r_1}{r_2}, \text{ whence } x = \frac{L r_1}{r_2},$$

where L is the total length of the main, and x the distance to the fault.

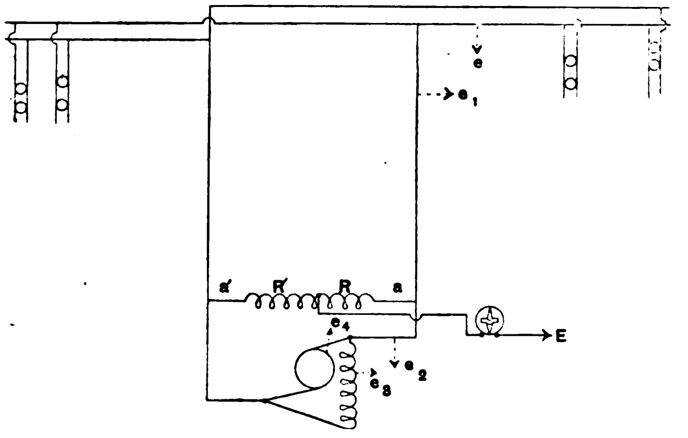
Since $$r_2 = \frac{E - E_1}{2C},$$

the above equation may be written

$$x = \frac{L\, 2\, r_1 C}{E - E_1}.$$

If $r_1 > r_2$ the fault exists on the distributing network.

Considering the lamp circuits of an electric lighting system alone, the resistance at any time may be considered as composed of two parts in series; one part, the mains, having a constant resistance, and the other part, the distributing cables and lamps, having a resistance which varies with the number of lamps connected. By dividing the artificial circuit into a similar number of parts, the localisation of earth faults on the mains is rendered easier, and becomes a simple matter of inspection when the parts are properly proportioned. In the diagram the artificial circuit is divided into four parts a, a', R, R′.



a and a' are fixed resistances of the slide-wire pattern. R and R′ are resistances which are capable of being varied, by units, through a range which depends on the difference between the maximum and minimum currents to be transmitted by the cables under test. If we arrange the various parts of the artificial circuit so that

$$a + a' : R + R' :: 2\, r_2 : \frac{E_1}{C},$$

then, if the resistances a and a' are uniform throughout their length, the distance of a fault on either main will be proportional to the distance from the leaky cable at which a balance is obtained on a or a'. If the slide wires are divided into a number of equal divisions, corresponding to the length of the cable in yards, the point at which a fault exists may be read off without calculation.

Suppose, for example, we have a circuit feeding a distributing network 300 yards away. Let the maximum and minimum currents be 400 amperes and 40 amperes respectively. Let the resistance of each main be 0·02 ohm, and the difference of potential maintained at the distributing point 100 volts. Let the resistances $a\,a'$ be fixed at 10 ohms each, or 500 times that of the cables they represent. When the maximum current is being transmitted the resistance beyond the distributing point will be ¼ ohm, and the sum of the resistances R R′ must be 500 times this value, or 125 ohms.

Hence R and R′ will each require to be 62·5 ohms.

When the minimum current is being transmitted, R and R′ must each be 625 ohms, and these resistances must be capable of adjustment within this range. The maximum fall of potential down each main will be 8 volts, or 0·027 volt per yard, and the fall of potential down $a\,a'$ will have this value per division.

A short consideration of the diagram will show that the apparatus, as developed, will distinguish between a fault in the dynamo circuits and one in the lamp circuits. Such faults as are indicated by e and e_1 have been considered. A fault at e_2 would deflect the galvanometer in precisely the same way as faults at either e or e_1, but it would be found impossible to obtain a balance on a however near to the cable the galvanometer connection was brought, since the potential of e_2 is greater than that at any point on the artificial circuit.

A fault at e_3 may be distinguished from e and e_1 by varying the current slightly in the shunt circuit and keeping the currents in the lamp circuit constant, after obtaining a preliminary balance. If the point of balance is altered, the fault exists in the shunt winding.

A fault at e_4 may be readily detected by the unsteady deflection of the galvanometer, due to it being traversed by alternating currents.

A faulty main may be distinguished from others worked from the same 'bus bars by varying the currents in them in turn until one is found which requires a fresh adjustment on the slide wires to preserve the balance previously obtained.

COAL CONSUMPTION IN AN EDISON STATION OF 1890 TYPE.*

At the new station of the Edison Electric Illuminating Company, of Boston, the possibility of feeding the old and comparatively uneconomical stations from it at times of light load by means of tie lines has been tried. This policy was begun in May, 1893, and besides proving a decided financial success, it has furnished some data as to the use of coal when the station is supplying the same

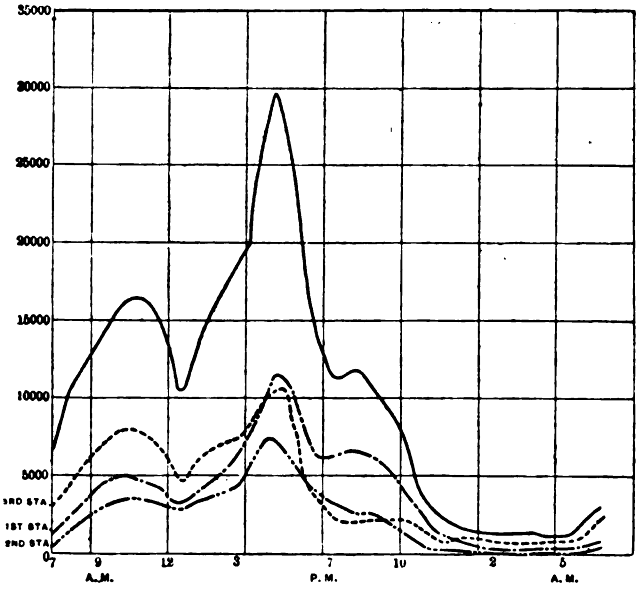


Fig. 1.—Date, December 12, 1894. Weather Cloudy.

maximum but very different average loads. The complete data are given by Mr. R. S. Hale in a Paper recently read before the Boston Society of Civil Engineers, entitled "Approximate Analysis of the Use of Coal in an Edison Electric Station of the Type Standard about 1890." The station selected by the author consists of 10 non-condensing Armington and Sims engines 15in. by 15½in., each belted to two No. 20 bipolar Edison 50-kilowatt dynamos, and supplied with steam at 100lb. gauge pressure from five boilers, Heine and Babcock and Wilcox, aggregating 12,390 sq. ft. of heating surface.

Comparing the monthly records of coal used and kilowatt hours generated since January, 1893, it is found that whenever the station is completely ready to run, the coal used may be expressed by the relation: Coal used = 500lb. per hour + 7½lb. per kilowatt-hour. 7½lb. per kilowatt-hour, or, roughly, 5½lb. per electrical horse-power hour is—after allowing for the over and under-loading of the

* Abstract from the *Electrical Engineer* of New York.

Digitized by Google

engines and for the fact that the valves may not be absolutely tight—not much worse than the figures obtained on this class of engines on test runs, and with this quality of coal. The constant loss of 500lb. per hour is divided into: Hot chimney gases, radiation from boilers, radiation from steam pipes, and steam leaks. The two latter, or steam pipe losses, were measured directly and found to amount to 300lb. and 600lb. steam per hour, or about 33lb. and 67lb. coal, respectively. The first two were measured together by shutting the stop valve of a boiler and finding how much coal it took to keep up the pressure without making any

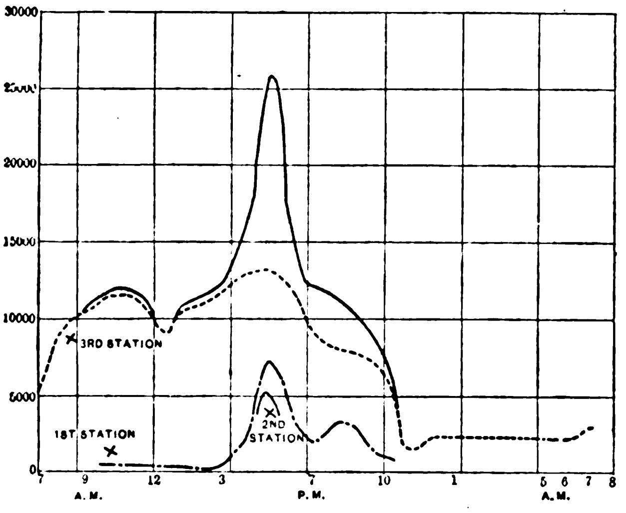

Fig. 2.—Date, December 13, 1894. Weather Fair.

steam, and this was found to nearly account for the remaining 400lb. of constant loss. This gave as the coal consumption:

33lb. coal per hour radiation from steam pipes.
67lb. ,, ,, steam leaks.
400lb. ,, ,, hot gases and radiation from boilers.

500lb. ,, ,, constant loss independent of load.
7½lb. per kilowatt-hour for all power produced.

In an appendix the author has given data from a similar Edison station where, on assuming the loss constant and comparing the Sunday and week-day figures, the loss was found to be about 1,750lb. per hour for a station about three times the size of that in Boston, and the net rate about 6·8lb. per kilowatt-hour, with higher steam pressure and some compound engines.

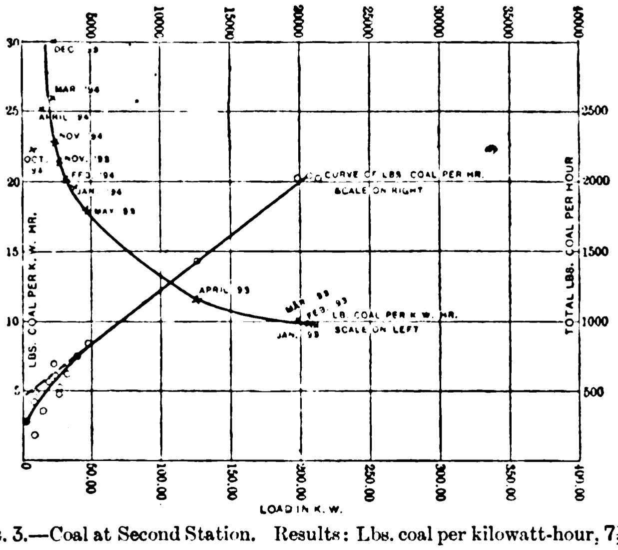

Fig. 3.—Coal at Second Station. Results: Lbs. coal per kilowatt-hour, 7½lb. Constant waste, 500lb. coal per hour = 180 tons per month.

We add from the Paper three curves. The first is an ordinary load diagram of the Boston system and of each of its three districts. The second gives the load generated at the different stations and the total, showing the effect of the tie lines in throwing the load to the economical station. The third gives the relation between the average kilowatts and the pounds of coal per hour and per kilowatt hour from which the equation which is the subject of the Paper is deduced. The Paper expressly disclaims being anything more than an approximation, but is of the greater value since its results are those of actual commercial running.

ON THE ELECTROLYSIS OF GASES.*

BY J. J. THOMSON, F.R.S.

In the experiments described in this Paper I have used the spectroscope to detect the decomposition of gases by the electric discharge and the movement of the ions in opposite directions along the discharg tube.

The method consists in sending the electric discharge through a tube so arranged that the spectra close to the positive and negative electrodes can easily be compared, thus the presence or absence of certain ions at these electrodes can be ascertained. This method is capable of much wider application than the one I previously used in my experiments on the "Electrolysis of Steam" † (*Proc.* Roy. Soc., Vol. LII., p. 90), the use of which is attended with very great difficulty for any substance other than steam. The earlier method has, however, the advantage of being a quantitative method—the present one is only qualitative.

In my former experiment with steam, when I worked at atmospheric pressure and varied the length of the spark, I found that when the spark length exceeded a certain length, d_1, there was an excess of hydrogen at the negative electrode and of oxygen at the positive, equal in amount to the quantities of hydrogen and oxygen liberated from a water voltameter placed in series with the steam tube. When the sparks were shorter than a certain length, d_2, the hydrogen appeared at the *positive*, the oxygen at the *negative* electrode, but the quantity of these gases was again equal to the quantities liberated in a water voltameter placed in series with the steam tube.

When the spark length was between d_1 and d_2 the effects were irregular, and there seemed to be no connection between the amounts of gases liberated in the steam tubes and those liberated in the voltameter.

In the following experiments in which the sparks were of constant length and the pressure was altered, corresponding effects were observed. Within certain limits of pressure definite and perfectly regular evidence of the separation of the ions of the gas sparked through was obtained; and the electrode at which a given ion appeared could be reversed by altering the pressure; there was, however, a range of pressures in which the separation of the ions was either not well marked or was irregular in character.

I shall begin by describing a very simple method of showing the separation of the ions produced by the discharge of electricity through a compound gas such as hydrochloric acid gas, which is applicable when the discharges through the constituent gases of the compound are of distinct and different colours; this is eminently the case with the hydrochloric acid gas, as the discharge through hydrogen in a capillary tube is red, through chlorine green.

Take a capillary tube of very fine bore, the finer the better (the tube I used was thermometer tubing of the finest bore I could procure), and insert platinum wires for electrodes in two small bulbs blown on the ends of the tube; then fill the tube with HCl gas, allowing it to run through the tube for a considerable time so as to get rid of any extraneous gas, and exhaust the tube so that the gas in it is at a very low pressure. Then when the discharge from a large induction coil passes through the tube, the following phenomena are observed. When first the discharge passes through the tube the colour is uniform throughout and of a greenish-grey; after the discharge has been passing for a little time the end of the tube next the cathode gets distinctly red, whilst that next the anode gets green; this difference in the colour at the ends of the tube goes on increasing until the tube presents a most striking appearance, the part near the cathode being bright red, while that near the anode is a bright green. The difference in colour attains a maximum value, and if the discharge is allowed to run for several hours the contrast between the two ends disappears to a very great extent; the discharge throughout the whole of the tube being pinkish and apparently passing mainly through hydrogen. This is doubtless due to the diffusion through the tube of the hydrogen which in the earlier stages of the discharge had accumulated about the cathode; one advantage of using very narrow tubes is that with them this diffusion is slow. When the tube is in this condition the colour of the discharge sometimes changes suddenly, and for a second or two is green instead of pink, showing that though in the main the discharge passes through hydrogen, it occasionally leaves the hydrogen and passes through the chlorine. This transference of the discharge from one constituent to another of a mixture of gases is not infrequently observed when the gases are mixed in certain proportions.

Some of these capillary tubes showed after the discharge had been passing through them for some time a peculiar patchy appearance, some portions of the tube being a much brighter red than the others, while other portions were green. In some tubes this occurred to such an extent that the discharge showed an irregularly striated appearance. This effect is due, I believe, gases or

* Paper read before the Royal Society.

moisture condensed on the walls of the capillary tube, and in some cases to irregularities in the chemical composition of the glass. I found that it did not occur if the tube before being used was heated for some time along its whole length to as high a temperature as it would stand without collapsing; this heating would tend to cleanse the walls of the tube. That differences in the quality of the gas also conspire to produce these patches is shown, I think, by the following phenomenon. A capillary tube of fine bore containing mercury vapour and a little water vapour developed a well-marked red patch; the tube was then heated for some inches in the neighbourhood of the patch. In general heating the tube makes the discharge yellow from the sodium vapour given off from the glass; in this case, however, the whole of the heated portion, with the exception of the patch, turned yellow; the patch itself withstood the heating, and continued to show the bright red colour characteristic of hydrogen.

Electrolytic Transport of one Gas through another.—A tube of the shape shown in Fig. 1 was made of the finest bore thermometer-tubing; the extremities, C and D, of the tube in which the electrodes were fused were bent down so as to be parallel to each other, and so near together that a slight motion of the tube suffices to bring either of the extremities in front of the slit of the spectroscope. The tube was mounted on a board moved by a lever; by moving this, the observer at the spectroscope could readily bring the spectrum of either the positive or negative electrode into the field of view. A side tube, A B, was fused to the middle of the main tube, and was provided with two taps; in the space between these taps a small quantity of any gas which it was desired to introduce into the main tube could be imprisoned, and could, by opening the tap A, be introduced into the discharge tube. The experiment consists in filling the main tube with a gas at a low pressure, observing the spectra at the two electrodes, then introducing by the side tube a very small quantity of gas into the main tube, and again observing the spectra at the two electrodes.

A tube was filled with hydrogen, and showed no trace of the chlorine spectra; a very small quantity of chlorine was then let in through the side tube (in performing this experiment it is necessary to be careful that only a very small quantity of chlorine is introduced). After the discharge had been running through the tube

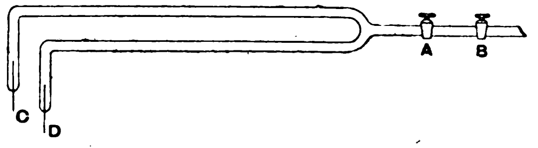

Fig. 1.

for a short time, the chlorine spectrum was found to be bright at the positive electrode, though no trace of it could be detected at the negative. When the discharge was kept on for some time, the chlorine spectrum, though still visible at the positive electrode, got fainter; it did not appear at all at the negative. If a considerable quantity of chlorine was introduced through the side tube, the chlorine spectrum was visible at both electrodes, though it was brighter at the positive than at the negative.

When the induction coil was reversed, so that what was before the positive electrode became the negative, the first effect observed was that the chlorine spectrum flashed out with great brilliancy at the old positive electrode, and was much brighter than at any previous period. This, however, only lasted for a second or two; the chlorine spectrum rapidly faded away and for a time was not visible at either electrode. Soon, however, the chlorine spectrum appeared at the new positive electrode, having thus been transferred from one end of the tube to the other.

On again reversing the coil the same phenomenon was repeated. There was apparently no limit to the number of times this effect may be obtained; at any rate, I have driven the chlorine from one end of a tube to the other 14 times in succession by reversing the coil. The chlorine is always driven to the positive electrode, showing that the chlorine ion carries a charge of negative electricity. The same effect was obtained when a little vapour of bromine was introduced into the tube instead of chlorine. When, however, the capillary tube was filled with chlorine instead of hydrogen, and a little vapour of bromine let into the tube, the bromine went to the *negative electrode* instead of the positive, as it did when introduced into the hydrogen tube. These experiments suggest that the two gases in the tube combine, and that the compound gas so formed is split up into ions which travel along the tube; that bromine when in combination with hydrogen is the negative ion, and therefore travels to the positive electrode; when, however, it is in combination with chlorine the bromine is the positive ion, and travels to the negative electrode.

Another experiment tried was to let a little vapour of sodium into the middle of a capillary tube filled with air at a low pressure. To prevent the sodium vapour condensing on the walls of the tube the whole tube was placed on a sand bath and the temperature raised so high that no condensation took place. After the discharge had run through the tube for about two hours the sand was removed from the tube, and the movement of the sodium vapour to the *negative* electrode was very apparent, even without using a spectroscope, as there was a great patch of yellow light near the negative electrode, and none in any other part of the tube.

Another experiment was to introduce a small quantity of hydrogen into a tube filled with air at a low pressure: the hydrogen made its way to the *negative* electrode. This experiment is a somewhat troublesome one, as it is exceedingly difficult to get these very fine capillary tubes so dry that the spectrum of the discharge does not show the hydrogen lines even before the hydrogen is introduced into the middle of the tube; indeed, I never succeeded in getting rid of the hydrogen lines at the very lowest pressures. By heating the tube and allowing dry air to run through it for a long time, however, I got the tube so dry that it did not show the hydrogen lines at a pressure quite low enough to allow the discharge to pass freely through it. When the tube was in this state and hydrogen was let into the middle of the tube, the hydrogen spectrum appeared at the negative electrode, but not at the positive.

The appearance of hydrogen at the negative electrode when mixed in a discharge tube with other gases has been described by Mr. Baly in a very interesting Paper in the *Phil. Mag.*, Vol. XXXV., p. 200.

The preceding experiments suggest, I think, that this separation of two gases, A and B, by the discharge is due to the decomposition by the discharge of a chemical compound formed of A and B, in which the A atoms have a charge of electricity of one sign, the B atoms a charge of electricity of the opposite sign; these charged atoms under the influence of the electromotive force in the tube travel in opposite directions. Further, it follows from the experiment with the bromine vapour in an atmosphere of chlorine that the sign of the electrical charge on an atom of the same substance is not invariable, but depends on the substance with which this atom is in combination. We shall find numerous other instances of this change in the sign of the charge on an atom in experiments described in a later part of this Paper.

Polarisation of the Electrodes.—This in the electrolysis of liquids is due to the accumulation at the electrodes of ions which have

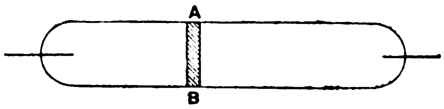

Fig. 2.

ceased to act as carriers of electricity. We have, I think, distinct evidence of a similar accumulation in the electrolysis of gases. For, as has been already described, after the discharge has been running for some time in one direction, giving the spectrum of some gas at one of the terminals, the spectrum of the gas at that terminal is momentarily brightened to a very great extent by suddenly reversing the direction of the discharge. After the current has been flowing for some time in one direction through, say, Cl in an atmosphere of H, the spectrum of the chlorine, though still visible at the positive electrode, gets faint, the chlorine apparently to a great extent ceasing to carry the discharge; when, however, the current is reversed, the atoms of chlorine can move freely, as they are not obstructed by the electrode, so that immediately after the reversal of the current there is probably more of the discharge carried by the chlorine than at any other time, and the chlorine spectrum is consequently brightest.

Discharge through a Compound Gas.—The separation of the ions by the discharge can be readily observed in a tube of the kind shown in Fig. 2.

It differs from an ordinary discharge tube merely in having a flat metal plate, A B, fastened across the tube. When the discharge passes through the tube, one side of the plate acts as a positive, the other as a negative, electrode. The tube is mounted on a stand, which the observer at the spectroscope can move by means of a lever so as to bring one side or other of the plate opposite the slit of the spectroscope; a very slight movement of the lever is sufficient to do this, so that the spectra at the two sides of the plate can readily be compared. I found that the results were more satisfactory when the current was kept flowing through the tube in one direction, and the tube moved so as to bring the spectra at the two electrodes into the field of view, than when the tube was kept fixed in one position and the current reversed. The latter method, however, suffices to show the separation of the ions in many cases, and it has the advantage of not requiring a plate across the tube; all that is necessary is to use for one of the terminals a disc whose plane is parallel to the slit of the spectroscope.

If the plate A B is thin it is necessary to fuse it into the glass tube all the way round; otherwise, when the pressure is low, the

Digitized by Google

discharge, instead of crossing the plate, goes through any little crevices there may be between the plate and the tube. The easiest way of making the tube is to use a plate about 0·5cm. thick, cut from an aluminium cylinder which tightly fits the tube; with a plate of this thickness the narrow spaces between the tube and the plate are so long that the discharge goes through the plate rather than through the crevices.

The tube was filled with the gas to be observed, and the spectra at the two sides of the plate compared. These spectra were in many cases found to differ in a very remarkable way; it was, however, only in exceptional cases that a line which was bright at one side of the plate was absolutely invisible on the other. The method used was to take two sets of lines, say A and B, as close together in the spectrum as possible and compare the brightness of these sets of lines on the two sides of the plate; if it was found that the A lines were brighter on the positive side of the plate than on the negative, while on the other hand the B lines were brighter on the negative side of the plate than on the positive, then it was inferred that electrolytic separation had occurred, and that the substance giving the A lines was in excess on the positive side of the plate, that giving the B lines on the negative. It is not safe to draw any conclusions from the variations in intensity of one line or one group of lines on the two sides of the plate, as the total quantity of light coming from the neighbourhood of the cathode often differs considerably from that coming from the anode. When, however, we get an increase in the brilliancy of one set of lines accompanied by a diminution in the brightness of another set, when we move across the plate we eliminate this source of error. The differences in the spectra at the two sides of the plate are most easily observed at pressures where there is not any very great difference between the luminosity of the cathode and the anode. As was mentioned at the beginning of the Paper, there is a range of pressure within which the effects are irregular, and no decided differences are observed between the spectra at the two sides of the plate. It is desirable in these experiments to keep the tube on to the pump as long as the experiment lasts, for the discharge always decomposes the compound gas, and unless the products of decomposition are continually pumped off and replaced by fresh supplies of the compound gas, the spectra of the discharge keep changing. With organic compounds this is especially necessary, as the character of the spectrum often changes entirely very shortly after the commencement of the discharge unless fresh gas is continually introduced.

In the following experiments the current was produced by a large induction coil with a mercury slow break.

When the tube was filled with hydrochloric acid gas at a low pressure, the separation of the hydrogen and chlorine was seen very distinctly, the hydrogen line being much brighter on the side of the plate which acted as the cathode (which we shall call the negative side of the plate) than on the positive side, while the chlorine, on the other hand, was brighter on the positive than on the negative side of the plate.

When the tube was filled with ammonia gas, the hydrogen lines were bright on the negative side of the plate, but were absent from the positive side, while on the positive side of the plate there was the positive pole spectrum of nitrogen, and on the negative side of the plate the negative pole spectrum of nitrogen and the hydrogen spectrum.

Sulphur Monochloride.—When the tube was filled with the vapour of this substance at a low pressure, the chlorine lines were brighter on the *negative* side of the plate than at the positive, while the sulphur lines were brighter at the positive side than at the negative. Thus the chlorine in this substance behaves in the opposite way to the chlorine in HCl; in the latter compound the chlorine ion has a charge of negative electricity, while in the sulphur monochloride it has a charge of positive electricity.

Influence of the Chemical Constitution of a Compound on the Sign of the Charge of Electricity on one of its Constituent Atoms.—In many organic compounds an atom of the electro-positive element hydrogen can be replaced by an atom of the electro-negative element chlorine without altering the type of the compound. Thus, for example, we can replace the four hydrogen atoms in CH_4 by chlorine atoms, getting successively the compound CH_3Cl, CH_2Cl_2, $CHCl_3$, and CCl_4. It seemed of interest to investigate what was the sign of the change of electricity on the chlorine atom in these compounds. The point is of some historical interest, as the possibility of substituting an electro-negative element in a compound for an electro-positive one was one of the chief objections assigned against the electro-chemical theory of Berzelius.

When the vapour of chloroform, $CHCl_3$, was placed in the tube, it was found that both the hydrogen and the chlorine lines were bright on the negative side of the plate, while they were absent from the positive side, and that any increase in the brightness of the hydrogen lines was accompanied by an increase in the brightness of those due to chlorine. The spectrum on the positive side of the plate was that called the carbonic oxide spectrum; when first the discharge passed through the tube, the spectrum on the positive side was the so-called candle spectrum, but this very rapidly changed to the carbonic oxide spectrum. The appearance of the hydrogen and chlorine spectra at the same side of the plate was also observed in methylene chloride and in ethylene chloride. Even when all the hydrogen in CH_4, was replaced by chlorine, as in carbon tetrachloride, CCl_4, the chlorine spectra still clung to the *negative* side of the plate. To test the point still further, I tried the analogous compound silicon tetrachloride, inserting a small jar in the circuit to brighten the spectrum. The chlorine spectrum was again brightest at the *negative* side of the plate, while the silicon spectrum was brightest at the positive. This is a very favourable case for the application of this method, as there are two silicon lines (wave-lengths 5058, 5043) quite close to two chlorine ones (wave-lengths 5102, 5078), so that their relative brightness can easily be compared. The experiment with the silicon tetrachloride is more conclusive than those with the carbon compounds, as with the latter the spectrum on the positive side of the plate is a band spectrum, and since the potential gradient when the discharge is passing is very much steeper on the negative side of the plate than on the positive, the effects observed might be supposed to be due to the circumstances on the negative side being better adapted for the production of line spectra than those on the positive. This explanation is not, however, applicable to the case of silicon tetrachloride, where the spectra on both sides of the plate are line spectra.

From these experiments it would appear that the chlorine atoms in the chlorine derivatives of methane are charged with electricity of the same sign as the hydrogen atoms they displace.

When we can determine the signs of the electrical charges carried by the atoms in a molecule of a compound, we can ascertain whether any given chemical reaction does or does not imply interchange between the electric charges on the atoms taking part in the reaction. Thus take the reaction

$$CH_4 + Cl_2 = CH_3Cl + HCl.$$

If we represent the sign of the charge of electricity carried by an atom by + or − placed below the symbol representing that atom, we may write the last reaction as

$$\underset{-}{C}\underset{+}{H_4} + \underset{+}{Cl}\underset{-}{Cl} = \underset{-}{C}\underset{+}{H_3}\underset{+}{Cl} + \underset{+}{H}\underset{-}{Cl},$$

so that this reaction could be produced by a rearrangement of the atoms without any alterations of their electrical charges.

If, however, we take the reaction—

$$\underset{+}{H}\underset{-}{H} + \underset{+}{Cl}\underset{-}{Cl} = 2\underset{+}{H}\underset{-}{Cl},$$

we see that in addition to a rearrangement of the atoms there must in this case be an interchange of electric charges between the atoms; for before combination half the hydrogen atoms had a negative charge, and half the chlorine atoms a positive one, whereas after combination no hydrogen atom has a negative charge, and no chlorine atom a positive one. We may thus distinguish between two classes of chemical reactions: (1) those which do not necessarily require any interchange of the electrical charges carried by the atom, and (2) those which do. It might, perhaps, repay investigation to see whether the occurrence of chemical change is affected by the presence of a third substance in the same way in these classes of chemical combination.

Another point to be considered is the effect of this difference between the chemical actions on the amount of heat developed during chemical combination. When hydrogen and chlorine combine the heat produced may be regarded as the joint effect of three processes:—

1. The splitting up of the molecules $(\underset{+}{H}\ \underset{-}{H})$ and $(\underset{+}{Cl}\ \underset{-}{Cl})$ into the atoms $\underset{+}{H}$, $\underset{-}{H}$, $\underset{+}{Cl}$, $\underset{-}{Cl}$.

2. A transference of electricity, by which the negative charge on one atom of hydrogen is replaced by an equal positive charge, while the positive charge on an atom of chlorine is replaced by an equal negative charge.

3. The combination of the positively electrified hydrogen atoms with the negatively electrified chlorine ones to form hydrochloric acid.

In that class of chemical action where the atoms retain their charge (2) is absent, so that if the change in energy occurring in the process (2) were considerable compared with the changes occurring in processes (1) and (3), the thermal effects of the two types of chemical combination ought to differ considerably. If the changes in energy occurring in the process (2) had a great preponderance over those occurring in (1) and (3), the thermal effects produced by the combination of two elements ought to follow very simple laws. For if $2\{H\}$ is the excess of the energy of an atom of hydrogen charged with the negative electron over the energy of the atom charged with the positive electron, $2\{Cl\}$ the excess of the energy of an atom of chlorine charged with the positive electron over the energy of the atom charged with the negative electron, then, if we could neglect the energy changes in

Digitized by Google

(1) and (3) compared with those in (2), the mechanical equivalent of the heat developed when a molecule of hydrogen combines with one of chlorine to form two molecules of hydrochloric acid would be equal to $2\{H\}+2\{Cl\}$. Thus we see that if the energy changes in (2) preponderated largely over those in (1) and (3), the heat produced when an element A combined with another element B to form the compound AB, could be expressed as the sum of two numbers {A} and {B}, where {A} depends solely on the element A, {B} solely on the element B. In some cases of chemical combination between dilute solutions there seems evidence that the heat produced can be expressed in this way (see Lothar Meyer, "The Evolution of the Doctrine of Affinity," *Phil. Mag.*, Vol. XXIII., p. 504), but when we attempt to apply the same law to combination between gases, it seems utterly to break down ; indicating that in such cases the greater part of the changes in energy occur in the splitting up of one set of molecules and the subsequent formation of others. This view seems to be supported by the phenomena attending the discharge of electricity through rarefied gases, for the smallest difference of potential which can send a discharge through an electrified gas (which we have reason to believe involves the splitting up of molecules into atoms), is very many times the electromotive force required to liberate the ions from an electrolyte, though the latter process requires changes in the electrical charges on the ions. These reasons seem to indicate that we can hardly expect to get any clear indication of the charges carried by the atoms in gaseous compounds from the study of the thermal changes which occur when gases enter into chemical combination.

Vapours of Organic Compounds.—These show very interesting differences between the spectra on the two sides of the plate when the discharge passes through them. Thus, when the discharge first passes through the vapour of ethyl alcohol, C_2H_6O, the spectrum on the positive side of the plate is the candle spectrum, that on the negative side the carbonic oxide spectrum. For some little time after the discharge commenced I could not detect any hydrogen lines on either side of the plate ; after a time, however, they appeared on the negative side but not on the positive. If the discharge was kept running for some time without letting a fresh supply of alcohol into the tube the "candle spectrum" on the positive side of the plate was replaced by the CO spectrum, which now occurred on both sides of the plate, accompanied on the negative side by the hydrogen spectrum. This is the appearance presented by all the compounds of carbon, oxygen, and hydrogen which I examined, when the spark had been passing through them for a considerable time, and it is what would occur if the vapour were decomposed by the spark into carbonic acid, water, and hydrogen.

The appearance of the candle spectrum on the positive side of the plate with the CO on the negative was observed in many other cases. Thus, on sparking through a tube filled with CO, I could not detect any difference between the spectra on the two sides of the plate, but when a little hydrogen was let into the tube the "candle spectrum" appeared on the positive side of the plate, the carbonic oxide spectrum on the negative. The same effect was observed in a tube filled with cyanogen mixed with a little hydrogen. When the tube was filled with the vapour of methyl alcohol, CH_3OH, the candle spectrum was on the positive side of the plate, the carbonic oxide and hydrogen spectra on the negative ; with this vapour, unlike that of ethyl alcohol, I could not detect any stage when the hydrogen spectrum was absent.

The first explanation which occurs to one of this phenomenon is that it is owing to the potential gradient at the negative side of the plate being steeper than that on the positive, so that we may imagine we have a fierce spark on the negative side, a mild one on the positive, and that the fierce spark gives the CO spectrum, the mild one the candle spectrum. There are, however, some phenomena which seem inconsistent with this explanation : in the first place, if the current is reversed after flowing in one direction, traces of the former spectra linger for some time at the sides of the plates, and, secondly, if the difference is due to the greater decomposition at the negative side of the plate, how is it that in the case of the vapour of ethyl alcohol the hydrogen spectrum is not seen, at the commencement of the discharge, on the negative side of the plate ? It only appears after the discharge has passed through for some time, when hydrogen has probably been set free by the decomposition of the vapour by the discharge. If the absence of the candle spectrum from the negative side of the plate is due to the spark being so intense that the hydro-carbon which is supposed to be the origin of this spectrum cannot exist, then we ought to see the spectra of the substances which result from the decomposition of the hydro-carbon—*i.e.*, we ought to see the hydrogen spectrum at the negative electrode. The view which seems most in accordance with the results of observations on the discharge through these vapours is that the "candle spectrum" is the spectrum of carbon when the atom is charged with negative electricity, or of some compound of carbon in which its atom is negatively charged, while the "carbonic oxide" spectrum is the spectrum of carbon when the atom is charged with positive electricity, or of some compound in which the carbon atom is positively charged.

Discharge through an Elementary Gas.—It has long been known that when the discharge passes through some elementary gases, the spectra at the two electrodes are different. This was first shown to be the case for nitrogen ; then Dr. Schuster showed that the same thing occurred with oxygen, and recently Mr. Crookes has shown that it is also true in the case of argon. I have observed a very striking change in the relative brilliancy of the red and green hydrogen lines at the two electrodes. When the tube with the plate across it was filled with hydrogen at a low pressure, then on the positive side of the plate the red line tends to be brighter than the green, while on the negative side the green line tends to be brighter than the red ; in some tubes this was so marked that on the positive side of the plate the red line was bright, and the green invisible, while on the negative side of the plate the green line was bright, and the red invisible. The spectroscope I was using weakened the red rays much more than the green, so that I cannot be sure that the red rays were really altogether obliterated on the negative side of the plate ; the above experiment is, however, sufficient to show that on the positive side of the plate the red rays are more easily excited than the green, while on the negative side the green line is more easily excited than the red. On the negative side of the plate we have an excess of positively charged hydrogen atoms, while on the positive side of the plate there is an excess of negatively charged hydrogen atoms, and I am inclined to attribute the difference in the spectra partly at any rate to the difference in properties between a positively and a negatively charged hydrogen atom. The reason I do not attribute it wholly to the difference in the potential gradient on the two sides of the plate is that the effect is not reversed immediately, but only gradually on reversing the coil, the former spectra clinging for some time to the sides of the plate.

Chlorine.—I have made a great many experiments to see if there is any difference between the spectra given by chlorine on the two sides of the plate, but with negative results. Chlorine seems a gas in which we might expect to find this effect, for as Dr. Schuster, in his Report on Spectrum Analysis, says, the behaviour of its spectrum indicates that we have several spectra superposed. I have not, however, been able to effect a separation of its spectra ; the differences I observed between the spectra on the two sides of the plate were irregular, and due, I think, to impurities producing effects like those observed when the discharge passes through a compound gas. However, as has been mentioned before, there is even in the case of gases where distinct evidence of separation can be obtained, a region of pressure within which the effects are irregular, and I ascribe my failure to observe separation in the case of chlorine to my having failed to get the relation between the intensity of the discharge and the pressure so adjusted as to get outside this irregular region. The cases, however, in which distinct differences between the spectra of a simple gas occur at the two electrodes, seem to indicate that the spectrum given by an element is influenced by the sign of the electrical charge carried by its atoms.

I have made some experiments to determine whether there was any separation produced in a mixture of equal volumes of hydrogen and chlorine kept in the dark, when a considerable difference of potential though not sufficient to produce discharge was maintained between the two electrodes. The parts of the tube adjacent to the two electrodes could be shut off from each other by a tap, and the amount of chlorine in the two sides was determined by absorbing it by caustic potash. The mixture was at atmospheric pressure, and the electrodes were maintained at a potential difference of about 1,200 volts by connecting them to a large battery of small storage cells. The potential difference between the terminals was maintained for about 16 hours on three separate occasions, but on analysing the vessels surrounding the two electrodes, the amount of chlorine in the vessel adjacent to the negative electrode did not differ from that in the vessel adjacent to the positive electrode by more than 1 per cent., and this could be accounted for by errors of experiments, as test experiments in which the mixture had not been exposed to the electric field, gave differences comparable with these. We should conclude from the preceding experiments that the molecules of a gas are not acted on by any appreciable translational force tending to move them from one place to another, when they are near to a body charged with electricity. To test this point further, two large terminals were placed in bulbs which were connected by a horizontal capillary tube, in which a drop of sulphuric acid was placed ; a difference in the pressure of the gas would cause the sulphuric acid to move, and the arrangement acts as a very delicate pressure gauge. The bulbs and tube were filled with chlorine at atmospheric pressure. The terminals were then connected to the electrodes of a battery giving a potential difference of 1,200 volts, but not the slightest movement of the drop of acid could be detected.

I wish to acknowledge the help I have received in making the preceding experiment from my assistant, Mr. E. Everett.

ELECTROLYSIS OF GASES.

Since the time when Prof. J. J. THOMSON gave experimental proof of the astonishing fact that, in the electrolysis of steam by a spark discharge, the ions of hydrogen and oxygen may each become either positively or negatively electrified, our ideas of the electrical condition of isolated atoms and single molecules have undergone considerable modification and enlargement. The time is probably past when we could affix a definite quantity of a definite kind of electricity to the atoms of each element, and believe that under no condition whatever could there be any alteration. In fact, we have learned that what in 1893 was regarded as exceptional, supernormal, almost it seemed paradoxical, must now be considered the expression of a law, as yet inexactly defined but nevertheless perceived, which extends over a wide range of chemical phenomena. Not alone the ions of electrolysed steam, but certainly a wide class of, and possibly all, electrolytic ions are capable of this remarkable reversal of electrification.

This fact, among a number of others of equal importance relative to molecular physics, is very cogently demonstrated in the series of charming experiments with which Prof. J. J. THOMSON recently delighted a Royal Society audience. Our readers will find a reprint of Prof. THOMSON's Paper in our issue this week. One of the most striking of the confirmations of the fact we have just referred to is the series of experiments on the group of compounds formed by the successive replacement of the hydrogen in CH_4 by chlorine atoms. It must be borne in mind that in the electrolysis of simple HCl the hydrogen collects at the cathode, being positive, while the negative chlorine is found at the anode. But in the series of compounds just referred to, the electrolysis of the vapours results in both hydrogen and chlorine collecting at the negative electrode, both these ions therefore becoming positive. And even when all the hydrogen in CH_4 has been replaced by chlorine, in carbon tetrachloride, the electrolysis of the vapour results in chlorine being found only at the negative electrode.

Further—and this supports the view that in certain allied groups of compounds, such as the tetrachlorides, an element will be electrically opposite to what it is in other groups, such as the chlorides—if the analogous compound, silicon

Digitized by Google

tetrachloride, is substituted for the carbon compound the chlorine behaves in precisely the same way as before. Prof. THOMSON points out the historic interest there is in this series of experiments; inasmuch as, by showing that a "normally" negative element may replace a "normally" positive one, it disproves the objection raised against the electro-chemical theory of Berzelius.

The explanation which Prof. THOMSON puts forward, of the transport in opposite directions of the two ions of an electrolytic gas, is the perfectly natural one that "the separation of two gases, A and B, by the discharge is due to the decomposition by the discharge of a chemical compound formed of A and B, in which the A atoms have a charge of electricity of one sign, the B atoms a charge of electricity of the opposite sign." It is easy to see that this might be the case where the gases are already introduced into the apparatus in a combined state; but it is not so evident that where two gases are merely admixed, a true chemical combination between them, atom by atom, must momentarily ensue before there can be any directive motion of the ions. If this latter supposition is correct, only those admixed gases could be electrolytically separated by spark discharge, which are in themselves capable of direct chemical combination. A test case might be instituted, by making one of the gases argon and the other an elementary gas with which it has stubbornly refused to enter into combination. Yet, even then, there would be room for the horrid doubt, whether the argon had not accommodatingly entered into an evanescent combination in order ultimately to get further separated from the other element!

The new addition to the instruments of electro-chemical research which Prof. THOMSON has made in his method of spectroscopically examining gases in the process of being electrolysed, seems likely to prove doubly useful; for on the one hand it enables us to learn more of molecular and atomic phenomena, while on the other hand it reveals new phases of the habits, so to say, of a spark discharge. Referring briefly to this second matter, we may notice the curious fact that a spark discharge, when passing through a seemingly homogeneous mixture of two different gases, will sometimes confine itself to the molecules of the one, and sometimes equally exclusively to the molecules of the other. It is as if lightning should sometimes pass entirely through the nitrogen, and at other times only through the oxygen, of the atmosphere.

Reverting to the chemical side of the matter once more, we may note, in conclusion, the importance of this method of investigation as a further test of the elementary condition of a gas. Its value in this respect lies not so much in its ability to prove an elementary state as to disprove it. If the lines of the spectra at one of the spark terminals become altered, relatively to those at the other terminal, when the discharge is reversed, the presumption is strongly in favour of there being a compound in the tube, but if there is no relative change it would be hasty to infer an elementary state. Yet it is curious that chlorine, believed to be an element, but the spectrum of which in some respects behaves like that of a compound body, exhibits not the slightest indication of its complexity when examined spectroscopically under spark discharge. The spectra at the two terminals, Prof. THOMSON has found, are absolutely identical; or, in other words, the atom is spectroscopically the same whether at the anode or the cathode. So far as this is any test, it goes to support the view that the complexity or compositeness of the chlorine spectrum arises from an infra-elementary complexity of the chlorine atom. Prof. CROOKES has delighted us with his charming hypothesis of the genesis of the elements; and his view that the atoms of any element are not always identical, but seem to vary between certain limits, is supported by the spectra of the metals of the rare earths. The explanation Prof. CROOKES has offered is, that an atom is built up of a number of slightly different subatoms of infra-elementary bodies, the differences between them being finely shaded. Possibly it is to some such complex atomic structure as this that the complications of the chlorine spectrum are due. Yet this is not made absolutely certain by the failure of the electric spark discharge to resolve chlorine into simpler constituents; for it is logically conceivable that chlorine may consist of two real elements, which, however, cannot be electrolytically separated in this way.

REVIEWS.

The Management of Dynamos. By G. W. LUMMIS-PATERSON. (London: Crosby Lockwood and Son.)

There has been a tendency of late to flood the book market with small unpretentious volumes purporting to give instructions to mechanics, engineers, students, and others interested in the running of dynamo electric machinery. It is needless to say that the majority of these are not only useless, but in many cases probably productive of harm. They cover too much ground to state anything in a clear manner and usually make a terrible mess of the theoretical parts of the subject, involving the units in inextricable confusion, and hopelessly mixing up power and energy. If it be necessary for the authors to appear in print they should confine themselves to practice, wherein they are generally fairly safe, and leave the exposition of theory to its legitimate exponents who occupy the seats of wisdom in our technical colleges. The book before us is perhaps rather above the average of its class; but if a knowledge of the principles touched upon in the first three chapters were taken for granted—no reader will ever grasp them from the text—much time might be saved. And if the reader were referred to one of the standard works for the construction of dynamos it would be much to his advantage, and he would have more time and perhaps more inclination to study the section on the practical management and working of dynamos, which is well written and contains some instructive hints. We cannot help thinking, however, that hints to dynamo tenders, to be of real use, should be confined to one side of a printed sheet pasted on a board and hung up in the engine house.

Solution and Electrolysis. By W. C. DAMPIER WHETHAM, M.A. (London: C. J. Clay and Sons.)

In this work of 283 pages we have a concise account of the modern theories of solution and electrolysis, and of the experimental facts on which they are based. For a considerable portion of the first six chapters the author expresses his indebtedness to Ostwald's "Lehrbuch der Allgemeinen Chemie," and for a fuller account of the developments of the dissociation theory he refers the reader to the second volume of that book, and to Prof. Nernst's "Theoretische Chemie." In these chapters the properties of solutions and of Van't Hoff's application of Boyle's law to them are very clearly set forth. In the succeeding pages we have an historical sketch of the principal facts of electrolysis as they have been noted from time to time, leading us up to the modern theories based on the intimate relation which has been observed to exist between the conductivity of electrolytes and their other physical and chemical properties. The quantitative agreement which has been observed to exist between the molecular conductivities, the abnormal value of the osmotic pressures, and the specific chemical affinities of electrolytes, certainly show that the peculiar condition which the author terms "ionisation" is the chief cause of them all. The explanation of the real physical meaning of ionisation is then sought, but the author is careful to point out that no hypothesis advanced merely to explain

Digitized by Google

observed facts rests on the same sure ground as a theoretical idea which is a necessary consequence of those facts. The dissociation theory of electrolytes, which has been worked out by Arrhenius, Kohlrausch, Ostwald and Nernst on Van't Hoff's view of the nature of solutions is explained, and the hydrate theory of solution as put forward by Armstrong, Pickering and others is discussed, and the author shows how the two hypotheses may be reconciled.

This book is a valuable addition to the literature on the subject, containing, as it does, a great number of tables and curves; and the way in which the equations are numbered, and the frequent references from one part of the book to the other, render the mathematical reasoning much more easy to follow than is often the case in such works. In the appendix is given a reprint from the British Association Report of 1893 of the valuable collection of data on the conductivity and migration constants of solutions which was made by the Rev. T. C. Fitzpatrick.

Indicator Diagram Record Book. Compiled by J. Wright, M.I.M.E. Edited by H. T. Wright. (London. 1895.)

The title of this book clearly indicates the use for which it is prepared—to contain the graphic and tabular records of indicator diagrams. To suit this special purpose, the book is made some 10in. wide and 3¼in. long, the pages being bound at the shorter side. The early parts include "Hints on Taking Diagrams," and a number of mathematical and steam tables. Then follow 100 forms, upon which the records of actual diagrams are to be made. Each form bears, at the left-hand end, squared rulings with scales for plotting diagrams; and the rest of its surface is ruled for various numerical entries and remarks. Each form extends over two pages, and is so complete that we are unable to think of any further engine datum that could be added; indeed, we fancy most engineers get along without troubling themselves about half the things that have a place provided for them in this sumptuous record book. We would suggest, however, that these forms should be numbered consecutively; and that somewhere in the book, preferably at one end or the other, a a blank index should be provided, so that the user might be able quickly to hunt up his elegant records. As matters stand now the user must number the forms for himself; and he will be sorely put to it, to find a place for an index. But, after all, when do engineers stand in need of a gilt-edged, leather-bound, fifteen-shilling repository of their indicator tests?

NOTES ON SOME EXPERIMENTS WITH ELECTROMAGNETIC MECHANISM.

BY P. V. McMAHON.

(Continued from page 496.)

Another experiment on the shape of cross-pieces was tried. The results are given on Fig. 14 (see page 495, *The Electrician*, August 9th). A zig-zag shaped cross-piece (Fig. 18) was used in *b*, and a cigar-shaped cross-piece (Fig. 19) in *c*. The zig-zag shape was used to allow the end of the core to go more into the coil; the straight cross-piece prevented this by reason of the flange of the coil stopping further travel. Comparing the curves we see that the ½ sq. in. straight cross-piece gives the greatest travel, 5·3in., for a variation of 1,100 ampere-turns. The zig-zag and cigar-shaped cross-pieces (curves *b* and *c*) have a travel of 4·4in. for the same variation. The zig-zag cross-piece gives a much straighter curve in the middle, but bends over earlier than *a* or *c*. The cigar-shaped cross-piece seems to have no advantage over the ordinary straight iron cross-pieces. The sketches of these cross-pieces are about one-fourth actual size. The curve *b* starts higher up on diagram than *a* or *c*. This is due to the point of the core being 1in. outside the coil at the beginning of the travel, on account of the knee of the cross-piece resting against the flange of the coil at starting.

The curve obtained with the ½ sq. in. iron cross-piece is drawn again on Figs. 13 and 14 (as this cross-piece gave the best result) in order to more readily compare the change in the shape of curve produced by the alteration in the cross-piece.

On Fig. 20 are given eight curves, obtained under the following conditions:—In *a* the brass cross-piece was as in Fig. 12, curve *a*, but the travel is measured higher up on the curve to

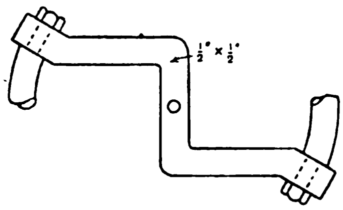

Fig. 18.—Zig-Zag Cross Piece.

compare with *b*, in which one core was 6in. and the other 8in. long. The travel with the two 8in. cores for a variation of 1,250 ampere-turns was 3·7in., while the travel in which the shorter core was used was only 2·6in. for the same variation of excitation. Inspection of this curve makes it clear that it is quite different from those which preceded it. The curve seems to be made up of two straight lines, with a small irregular piece connecting them. This irregular piece corresponds with that part of the travel where the ends of the cores are passing through the weak magnetic

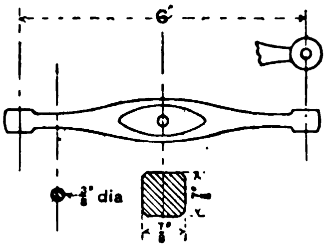

Fig. 19.—Cigar Cross Piece.

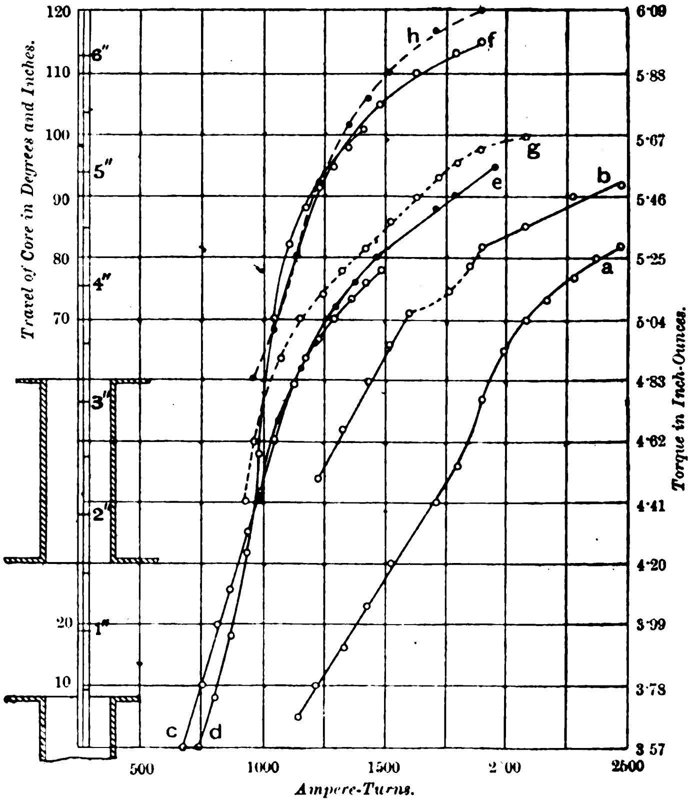

Fig. 20.

field between the coils. The first point on the curve, or the first position in which balance was obtained between the controlling spring, and the force due to the ampere-turns, is about 2in. higher than in the *a* curve, or when both cores were 8in. long; the curve then continues a straight line

Digitized by Google

until the point of the 8in. core is 3·3in. outside its coil, and the 6in. core 1·3in. outside the other coil; the travel then proceeds at a slower rate for a distance of 0·55in., and continues in a straight line again to the end of the travel, a distance of 0 55in. A point worthy of notice in connection with this irregular part of the curve is that when the two 8in. cores are used, the travel of the cores is quicker than the first part, and with one 8in. and one 6in. core the state of affairs is reversed. It may be mentioned that in this and the following experiments, with one 8in. core the spindle was balanced by a brass sector on the opposite side to the core.

The remaining six curves (c to h) were obtained from one eight inch core, as shown Fig. 21, which is drawn to scale half-size. The coils were arranged in this manner to try the effect of making the coil longer with respect to the core, and also the effect of bunching the winding or making the coil itself taper. This latter effect was obtained by shunting the top coil with a resistance equivalent to its own; thus the top coil had half the number of ampere-turns the bottom coil contained. Owing to the coils being square the arrangement was not quite the same as if the whole space between the outside flanges was filled with wire; this becomes more evident when we examine the position of the second coil on Fig. 20, which shows the position if the coil was straight instead of circular.

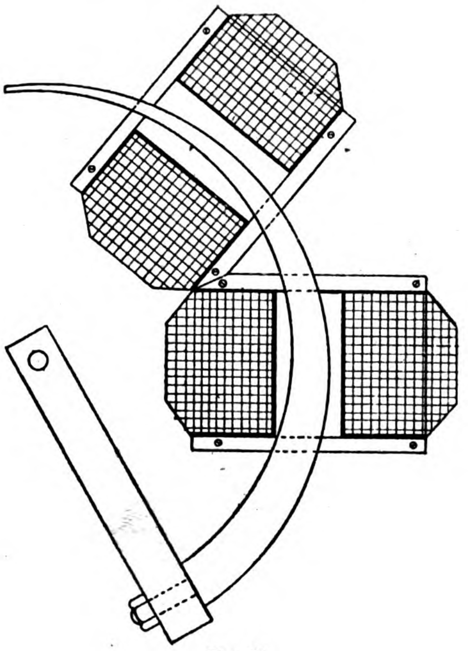

FIG 21.

The curve c was obtained with one 8in. core, and the bottom coil with the brass cross-piece; here for a variation of 750 ampere-turns the travel was 3·8in.; where the iron cross-piece was used, curve d, the travel for the same variation of excitation was 5·4in. Here the effect of using the iron cross-piece is more apparent than when the two cores were used, the increase in travel with the iron over brass being about 42 per cent. Comparing this travel with one core and one coil with curve d (Fig. 12), we have a travel of 5·4in. for 750 ampere-turns variation, as against 5·7in. for 1,250 ampere-turns variation, and the curve d (Fig. 20) is a nearer approach to a straight line than that obtained with two cores. However, the curves have the same general shape; d (Fig. 20) rises at first in a straight line (nearly) and thence more quickly; this seems to happen as the iron cross-piece comes into the influence of the coil's stray field, then the curve bends over as if the iron were getting saturated, but not so much as in the curve d, Fig. 12.

The effect of shunting the top coil was next tried with both brass and iron cross-pieces, curve e and f. The travel here was 2·3in. in each case for a variation of 750 ampere-turns. It is noticeable that the straight part of the curve comes last with the brass cross-piece and first when the iron cross-piece is used; also the core is drawn further into the coil when the iron cross-piece is used.

Next the two coils were tried coupled in series under the same conditions, as in e and f, as regards cross-pieces. For the same variation of excitation the travel, when the brass cross-piece was used, curve g, was 1·5in., and with the iron cross-piece, curve h, the travel was 2·6in. The curve g is a straight line from the first point on the curve (here the top of the core is about one-third into the second coil) for about $1\frac{1}{4}$in. and bends over, giving a second straight line for almost the remainder of the travel. The curve h is very similar to curve d (one

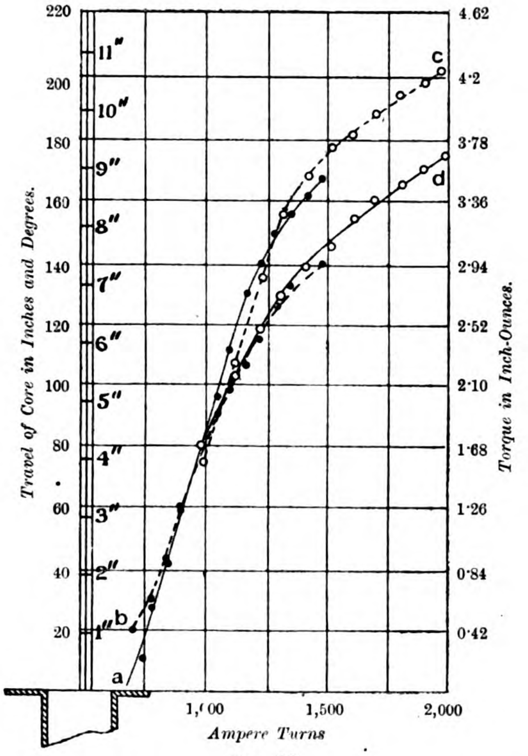

FIG. 22.

coil), but has a much shorter travel. Inspection of the curves also shows that when two coils are used (top not shunted) the core is drawn more into the coil with both iron and brass cross-pieces than when the top coil is shunted.

Lastly, four curves were obtained with these coils, and a core 14in. long, $\frac{9}{16}$in. diameter at bottom, and $\frac{1}{8}$in. diameter at top, bent into an arc of 3in. radius as before (Fig. 23). In the two curves a and b (Fig. 22) one coil was used—a with iron cross-piece, and b with brass cross-piece; here, for a variation of

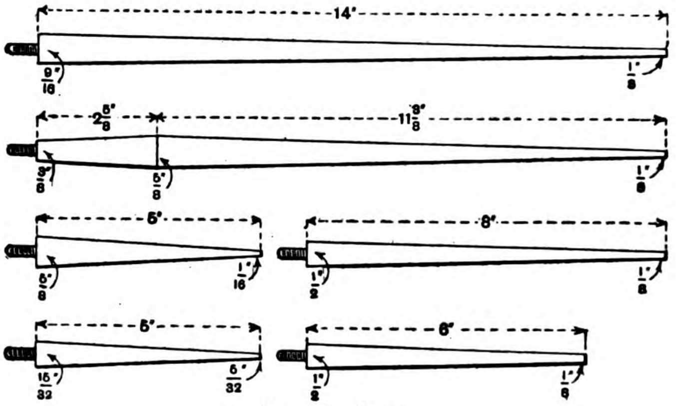

FIG. 23.—Cores.

750 ampere-turns, the travel is 8·1in. and 6·2in. respectively, as against 5·4in. and 3·8in. when the 8in. long core was used. Using the two coils in series, as in g and h (Fig. 20), the travel for the same variation of excitation was in e (iron cross-piece) 6·1in., and d (brass cross-piece) 4·4in. It is noteworty that the curves obtained under all conditions with the 14in. core are more nearly straight lines than those obtained with the 8in. core under similar conditions of torque and variation of

Digitized by Google

excitation. In fact, the curve *a* is a perfectly straight line for 7·5in. of its travel, and *d* the same for 4in. Here not only is a straighter curve obtained when the iron cross-piece is used, but the total travel is also greater than with the brass cross-piece. In this experiment the point of the core was flush with the outside edge of the coil when the spring had no initial tension and no current flowing.

For greater convenience the results are tabulated in Table IV., which requires no further explanation.

Table IV.

* Position taken higher up on curve to correspond with curve *d*, Fig. 20.

From the foregoing remarks and curves it would seem that the best results may be obtained with one core and one coil only, or, in other words, the core must be as long as possible and the coil short. Also when the core is long in comparison with the coil, the disturbance due to the external field of the coil seems to decrease with both iron and brass cross-pieces.

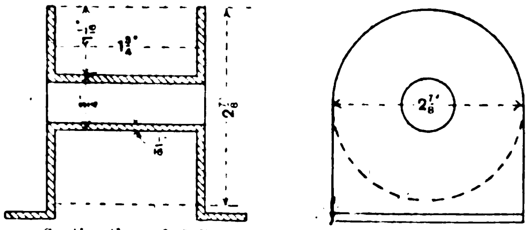

Fig. 24.

As it was necessary to use the piece of mechanism (when a suitable one was found) on a circuit of about 300 volts, the coils in the remaining experiments on the solenoid and core were made with two coils of very high resistance wound with platinoid wire. It was found more convenient to wind the bobbin with platinoid wire to stand 300 volts than winding it with copper wire and putting a resistance in series with the coil, although the latter method would have been the least expensive. Before winding the coil it was found impossible to get any published data as to what gauge wire to use; therefore full particulars of the two coils and some temperature tests are given in the hope that the results may prove useful.

The smaller coil was wound with No. 30 B.W.G. double silk-covered platinoid wire, had 5,650 turns, and a resistance 4,326 ω at 22°C. The dimensions of the bobbin are given in annexed sketch (Fig. 24).

With a difference of potential of 350 volts across the terminals for about an hour, the temperature, as shown by a thermometer placed inside the coil, with its bulb touching the metal and covered with wool, was 70°C., the temperature of the room being 22°C.

The other coil was wound with 6,154 turns of No. 28 B.W.G. double silk-covered wire, and had a resistance of 4,390 *w*. The weight of wire on coil was 3lb. 5oz. The dimensions of the bobbin are given in the annexed sketch (Fig. 25).

With a difference of potential of 285 volts across terminals of coil for an hour, and the thermometer arranged as in the smaller coil, the temperature rose to 50°C., the room being 22°C. The thermometer was then placed on the outside of the coil, its bulb touching the winding and the metal flange, the remaining portion of the bulb being covered with wool. The

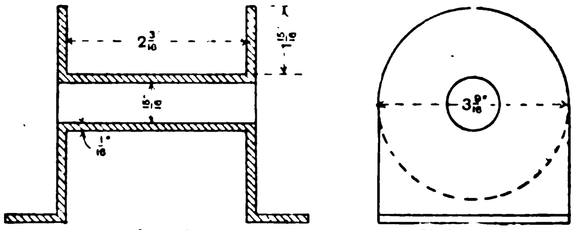

Fig. 25.

coil was kept in circuit for 2½ hours, and the temperature rose to 75°C., that of the room being 22°C. as before.

In Fig. 26 are given three curves obtained with the large coil, and three different cores under the same conditions as regards the spring, which was smaller and weaker than that used in the first set of experiments. This spring was 36in. long by 0 275in. wide by 0·013in. thick in convolution, and was calibrated as before, giving a perfectly straight line. Every 10deg. turned through by spring corresponding to a torque of 0·11 inch-ounces. The curves *a*, *b*, *c*, are chosen from several

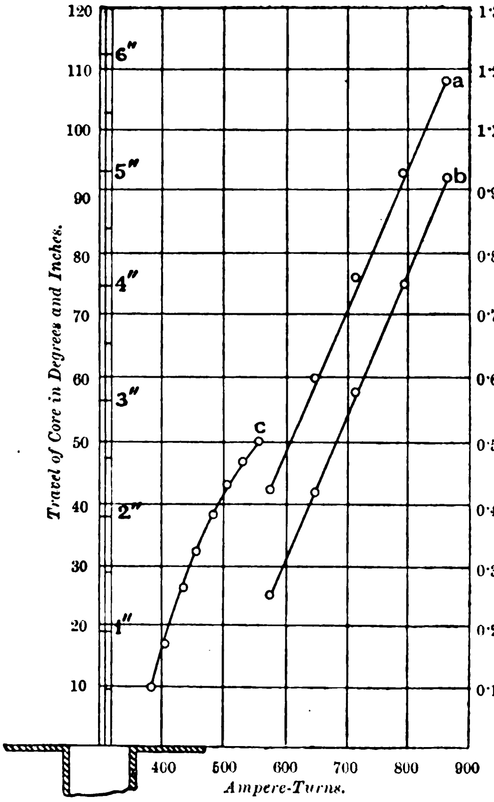

Fig. 26.

as being the best suited for our purpose (or nearest a straight line), and show the effect of different cores, each with the ½ sq. in. iron cross-arm. Here for the same variation of excitation, viz., 200 ampere-turns, the travel is practically the same, although the cores are widely different, *a* being obtained with a core 14in. long (Fig. 23); in *b* the core was 14in. long, but was double-tapered (Fig. 23), and in *c* the core was only 5in. long. As regards the shape of curve, there is no difference between the single and double-taper core of the same length,

Digitized by Google

but the single-taper a is drawn more into the coil for the same excitation than the double-taper b. The curve c is straight until the point of the core is 1·7in. outside coil, and then bends over slightly. Although this 5in. core does not give as good a curve as the 14in. cores, yet the arrangement with the 5in. core is very much more sensitive than with the 14in. cores, the smallest variation in the excitation giving an immediate movement of the core, and, in addition, it is more dead-beat. This is no doubt due to the lightness of the short core as compared with the long one.

Fig. 27, curves a and b were obtained with the smaller coil and the 5in. core (Fig. 3), and show the effect of using the iron

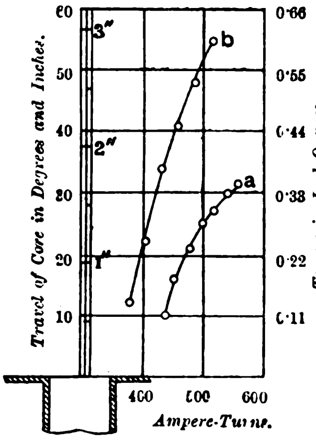

FIG. 27.

and brass cross-pieces. For a variation of 120 ampere-turns the travel in a, where brass cross-piece was used, was only 1·1in., as against 2·3in. travel when the iron cross-piece was used. Here, where the core is short compared with the length of the coil (or the core about $2\frac{3}{4}$ times the coil length), there is a decided gain by using an iron cross-piece, both as regards travel and shape of curve.

Fig. 28, curves a, b and c show the effect of altering the taper of the core and of adding the iron disc used in curve b, Fig 13, to the base of the core. The smaller coil was used here, and the two 5in. taper cores, a $\frac{5}{8}$in. diameter at base and $\frac{1}{16}$in.

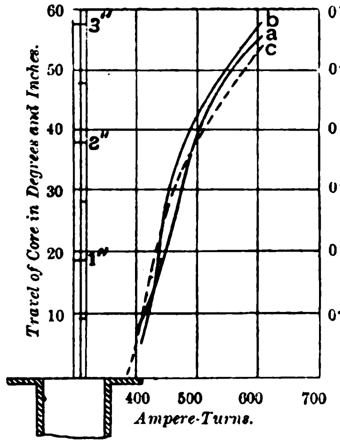

FIG. 28.

diameter at point, and c $\frac{15}{32}$in. diameter at bottom and $\frac{5}{32}$in. diameter at point (Fig. 23); the curve b is that obtained with the iron disc on the base of the 5in. core used for a. The $\frac{1}{2}$ sq. in. iron cross-piece was used in this experiment, and for a variation of 200 ampere-turns the travel is practically the same, being 2·8in. for a (quick taper core), 2·7in. for c (slow taper core), and 2·6in. for b (quick with disc attached). Here, in addition to a giving the greatest travel, it is also the straightest curve; c comes next in order of shape, and the addition of the disc to the end of the core gives a curve somewhat similar to that obtained when the two cores and two coils were used.

(To be continued.)

THE ELECTRIC LIGHTING OF THE CITY OF LONDONDERRY.*

BY JOHN CHRISTIE.

The idea of public lighting by electricity was first discussed by the Corporation so far back as March, 1888, but was allowed to drop. The matter was again brought up two years later, and it was then agreed to take out a Provisional Order. As the time wore on, and the Board of Trade required the Corporation to take some active steps in the matter if they wished to retain their powers, they, in September, 1892, called in Mr. H. W. Blake as consulting engineer, to advise them on a scheme. The following year the Corporation finally decided to adopt a scheme for the public lighting of the city by means of arc lamps. This scheme, prepared by Mr. Blake, was submitted to Dr. John Hopkinson, and on his approving of the specifications, &c., tenders for the plant were invited by advertisement, accepted, and gone on with as soon as the permission had been granted by the Local Government Board to borrow the necessary estimated capital of £15,000.

In the selection of a site for the station, the Corporation were particularly fortunate in obtaining on very favourable terms what had formerly been an old saw mill, situated in the Strand, at a distance of some 700 yards from the centre of the city, and extending back 230ft. to the quay, and having an opening on to the river, thus affording every facility for storing coal direct off the steamer, and also an ample supply of water for condensing purposes. At present there are only two boilers laid down. They are of the Lancashire type, constructed for a working pressure of 125lb. per square inch. The feed-water arrangements comprise two duplex double direct-acting pumps, each capable of supplying 900 gallons per hour against the maximum working pressure. The water is drawn from a storage tank of some 20,000 gallons capacity, placed on the roof of the boiler house, and supplied direct off the town mains. The economiser is one of Messrs. Green's. The steam is conveyed to the engine room by two lines of 9in. wrought-iron pipe, having 6in. branch pipes to each boiler; both lines are common to each engine. In the engine room are placed along one side three vertical compound-condensing engines of 150 I.H.P., made by a local firm of engineers, Messrs. Brown and Sons. The diameters of the cylinders are, high-pressure 11in., low-pressure 22in., and the stroke 18in. The average speed at which they are run is 145 revolutions per minute. Each engine has a jet condenser of its own placed under the floor of the engine room, the air pump being operated on a crank disc on the end of the shaft. The condensing water is supplied to each engine by a separate 4in. cast-iron pipe laid direct to the river, each pipe being fitted with a clack valve, rose head and mud box. A 9in. cast-iron pipe serves as a common discharge to all the engines. An auxiliary injection pipe off the town mains is provided to each engine to assist at starting if the tide is very low or a suction pipe gets choked. The speed of the engines is controlled by Hartnell's patent automatic expansion governor fitted on the crankshaft, which, by shifting the angle of advance of the high-pressure eccentric, varies the cut-off of the valve to suit the load. The distribution of steam is effected in the high-pressure cylinder by a piston valve, admitting the steam in the middle and exhausting at the outer edges, and in the low-pressure cylinder by an ordinary trick slide valve; by this arrangement the high-pressure piston gland is the only one which is subjected to the full working pressure. The fly-wheels are 8ft. in diameter and 24in. broad, and each weighs about 3 tons.

By means of two 10in. leather belts, each engine drives two dynamos, placed on sliding rails one behind the other. The dynamos are of the constant-current series type, made by Messrs. Siemens Bros. and Co. They are designed for an output of 10 amperes at 3,000 volts at 750 revolutions per minute. The machines have ring armatures rotating in a double magnetic field, and are fitted with copper commutators 18in. diameter, divided into segments, and insulated with mica. We have had them running constantly for nearly 18 months at 2,500 volts, and often having them subjected to the most severe strains possible, and they have given no trouble whatever; the sparking is not excessive and the wear on the commutators very small. To keep the current constant a very ingenious regulator is provided, which automatically varies the voltage to suit the number of lamps on circuit by rocking the brushes back or forward; with these regulators in gear it is almost impossible to get more than 10 amperes for any time, and they give the current just as well on short circuit as when the whole resistance of the circuit is on. Last winter we had ample opportunity of testing them through the high winds which were so prevalent.

The lighting of the city is divided into sections, each section having two circuits with lamps arranged alternately on different circuits. At present we have the lamps arranged on the four

* Abstract of a Paper read before the Incorporated Association of Municipal and County Engineers, at Londonderry.

Digitized by Google

circuits as follows: 40, 43, 41 and 48, or 172 in all; but extra lamps will most probably soon be looped in to bring the numbers on each circuit up to over 50, and do away with some more of the gas lamps which still exist in some of the smaller streets.

The cables consist of $\frac{7}{16}$ copper strand heavily insulated with vulcanised india-rubber, served with a covering of bituminised jute, armoured with galvanised steel wires, the whole being covered with jute steeped in a preservative compound and laid in the ground direct. The armouring is earthed at every lamp, and also at the station ends. There are some 34 miles of this cable laid, the longest circuit being about nine miles round, and the area lighted is, I think, one of the largest in the country. During the first six months after the plant was taken over by the Corporation we had a most unfortunate time of it, through failures of the lamp cut-outs, cables and other causes incidental to the start of such a large scheme. For a long time this made the electric light most unpopular with many, but Messrs. Siemens successfully surmounted all the many difficulties as they cropped up, and in the very depth of winter entirely relaid the whole of the cables without interrupting the lighting of the city. All these failures are happily a thing of the past, and now we rarely have even a single lamp failure reported.

All the lamps are of the well-known Brockie-Pell double-carbon 32-hour type, so that in winter they only require trimming every second day, whilst in summer once a week suffices. The lamps are fixed on ornamental cast-iron pillars 25ft. high, and pitched from 75 to 250 yards apart.

A brief description of our method of detecting faults on the circuits may be of interest to some of you. Daily insulation resistance tests of all the circuits are taken, and if any one shows below the normal it is carefully watched; should it become dangerously low, the position of the fault is first roughly located by means of a Kelvin electrostatic voltmeter of the ordinary type, reading up to 6,000 volts; the weights on the vane are adjusted so that the scale reads 50 volts per division. One terminal of the instrument is then earthed, and the other terminal connected to the positive and negative ends of the faulty circuit, and two readings obtained, which, assuming the voltage per lamp at 50, reads directly the number of lamps from either end about which the fault exists. By referring to the map we can at once go to almost the exact lamp, and by freeing the ends at the switch tell by means of a detector whether the fault lies in a lamp or a section of the cable between two lamps. This method I find saves an immense deal of trouble, rendering it unnecessary to split up a long circuit into several parts until the faulty one is found; and if the readings are carefully taken we can always spot the section within two lamps either way. If the fault proves to be in a lamp it is immediately remedied by replacing it with a spare one, and if in the cable and of low enough resistance it is at the earliest opportunity burned out dead to earth by temporarily earthing one end of the line at the station, when by means of the loop test taken on the section with a portable testing set, the exact position of the fault is located and cut out. I am glad to say, however, that such faults never occur in the cable we now have through any inherent weakness of the insulation, but have always been clearly traceable to pick marks caused by some careless workman, when opening the streets, accidentally striking the cable and neglecting to report it.

The cost of the whole scheme up to the present amounts to between £18,000 or £19,000. In winter during the long nights the works cost per lamp-hour were as low as 0·65d., and in summer when the runs were shortest they reached as high as 1·70d. per lamp-hour. So far as can be judged, the total costs, including everything, should not much exceed £19 per lamp per annum, which, considering the number of hours we run (over 3,000) is by no means excessive.

No attempt has yet been made by the Corporation to introduce private lighting.

CORRESPONDENCE.

MAGNETIC UNITS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is after hesitation, and with some reluctance, that I comply with your request to take part in the discussion of this question. The fact is I have not been able to see that the proposed new names and new units are needed. When so clever a man as Prof. Lodge takes all these pains, I should like to believe that his proposals are meeting a felt want. But by whom is the want felt? I hold strongly that in this matter necessity should be the mother of invention. Dr. Lodge offers us sundry bantlings for adoption, but where is the maternal parent? New names and new units will be worse than useless unless they quickly become familiar. The B. A. Committee may make them legal tender among electricians, but will they come to be current coin? Will the success that attended the invention of ohms, volts and amperes be repeated, even in minor degree? Only if the new names allow us to conceive magnetic quantities more easily or to specify them more tersely than we can already do. We are accustomed to say that the permeability of air is 1. Will the advantage of calling it the "inductivity" instead, and of saying that it is one millihenry per kilometre, be immediately obvious to practical men?

In some cases it is proposed simply to give a name to the C.G.S. unit, and in other cases to use a multiple of the C.G.S. unit and give that a name. Thus Mr. Evershed would have us call the C.G.S. unit of magnetic induction a "thom," while Dr. Lodge would take 10^8 of the same unit and call it a "weber." Why do either? So long as we stick faithfully to C.G.S. a number is enough. To say that the total induction through an armature is 25 millions is at least as convenient and precise as to say that it is 25 million "thoms" or 0·25 "webers." Dr. Lodge has chosen the magnitude of the "weber" so that an E.M.F. of one volt shall be excited in a conducting circuit through which the total induction changes at the rate of one "weber" per second. But this endeavour to connect the new unit with the volt, the ampere and the ohm results in making it inconveniently large. Better, I think, use C.G.S. pure and simple in dealing with the magnetic quantities, and introduce the needful power of 10 when we want to reckon volts.

Again, we are asked to accept a new name for the line-integral of magnetic force, which most of us (following Mr. Bosanquet) call the magnetomotive force. This quantity is of first-rate importance in relation to the magnetic circuit as a whole. But I doubt if the occasion ever arises in practice to reckon magnetomotive force except for the whole circuit. And so long as we are dealing with the magnetic circuit as a whole it is not likely that any new name will be more serviceable than the familiar and eminently practical "ampere-turns." When we want, for purposes of reckoning, to express the magnetomotive force in C.G.S. units, it is easy to multiply by $\frac{4\pi}{10}$; but ampere-turns is too expressive and explicit a phrase to require addition or change.

As to the magnetic force at any point (H), no new name is wanted, and the C.G.S. unit is all that could be wished in respect of magnitude.

I understand that it is proposed to use one and the same unit for the permeance of a magnetic circuit and for the self-induction of a coil or the mutual induction of two coils. These are quantities of the same dimension, and as Prof. Lodge points out, the self-induction of a coil of n turns is $4\pi n^2$, the permeance of the magnetic circuit through its coil. Mr. Baily's objection that the self-induction of a coil would be liable to confusion with the permeance of its core has much force. As to permeance, which is total induction divided by magnetomotive force, no special unit name seems necessary. Whether a unit name for self-induction and mutual induction is practically important I have no opinion. The invention and partial use of "secohm" on this side of the Atlantic and "henry" on the other suggest that it is. But in any case it would be unfortunate and confusing to give the "henry" a value different from that which has already been assigned to it. Will American electricians consent to make their old name have a new meaning? Moreover, though this is of less consequence, the unit now proposed is, like the "weber," inconveniently big. These are large prices to pay for the kind of consistency that is aimed at in Prof. Lodge's proposals.

One or two points may be noticed that have come up incidentally in this correspondence. Prof. S. P. Thompson speaks of the quantity which we write B as "unfortunately sometimes miscalled the induction, as though induction were not the operation of inducing." I have rarely heard it called anything else, and am content to follow Maxwell, who probably believed that induction, like deduction, might properly name the result of a process as well as the process itself.

Digitized by Google

To define μ as $\frac{d\mathbf{B}}{d\mathbf{H}}$ would, in regard to iron, make μ useless. It should be remembered that, owing to the complications of hysteresis, the term permeability as applied to iron has a special meaning. It is used to name the ratio of **B** to **H**, when **H** is either (*a*) applied without previous magnetisation, or (*b*) applied after previous magnetisation by an equal and opposite magnetic force. These two definitions do not give strictly the same result; but the values are so nearly alike that the difference is, in practice, unimportant.

As to Mr. Heaviside's invitation to formulate a theory of the process of magnetic induction in iron, I fear that the relation of **B** to **H** is far too complex—as depending on previous values of **B**—to admit of mathematical statement. That at least is the conclusion to which a study of the model with small magnets seemed to point, where the process of magnetisation was seen to occur through the breaking up and rearrangement of inter-molecular ties under the influence of the applied field.—Yours, &c., J. A. Ewing.

Festiniog, North Wales, Aug. 26, 1895.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Referring to the correspondence on the subject of magnetic units now going on in your columns, I am sorry to say that Prof. Thompson could not have named in this connection a less sympathetic individual than myself; as the alleged necessity for new units does not in the least appeal to me.

It is unnecessary to seek a new name for "one line of force" or for "1,000 lines of force," or for "a million lines of force." As well might we coin a new term for "one revolution," follow that up with another for "100 revolutions," and still a third for "1,000 revolutions"—a *kilorevolution* to wit. It is as easy to say that the total flux is "5,000 lines" as to say that it is 5 *kilolines*; and the "thom" of my friends at Woodfield Works I have never been able to understand. Substituting *thom* for *line*—I put it shortly, without writing *of force* after it—I have always regarded as the most awful example of unit mania extant.

As regards *the number of lines per square centimetre* or *induction*, denoted by **B** the world over, I do not see that we require special names for particular values of it. "Lines per square centimetre" = so many, or "the induction" = such a figure, or **B** = so much, seems to meet all cases. There are some I know who would like to have a name invented for 1,000 lines per square centimetre, but I am not amongst them. *Engineers* have gone on very well without such variety of terms. *They* do not require a distinct name for a speed of 30 miles an hour, and another for 60, or a special term for 100lb. pressure per square inch, and another for 120lb. Proposals of this kind made by anyone would very properly be regarded as ridiculous, and having been brought up in a practical school, I am consequently inclined to look down upon the senseless multiplicity of terms some electricians would have us adopt.

There remains *magnetising force* to be dealt with, and here I am still at a loss as to what is requiring new definition. Magnetising force is expressed in two different ways, either as the *line-integral* or *ampere-turns* accordingly as the constructive engineer regards one or other as the more convenient. What he has to determine is the magnetising force required for a given circuit, and this he finds from his iron data in the usual manner; but how it will help him to give a name to some particular value of magnetising force, whether expressed as the "line-integral" or "ampere-turns," and call it *unit magnetising force* I fail to see. Altering the unit of current is not to be thought of seriously for a moment. Magnetic quantities are only dealt with professionally, if I might so put it, while amperes, volts, watts and horse-power are dealt with commercially by everyone having the slightest connection with electrical matters. These quantities have become stereotyped as part and parcel of an industrial system, and even if a change were desirable, which it is not, they could not be altered with any greater facility than could the horse-power.

The advantage of having a universally received meaning for the terms in Prof. Thompson's paragraphs 5 and 6 seems to be more apparent than real. Whenever the relation between magnetic force and flux is given by any writer he is careful to state which way the magnetising force is computed, so I do not think any confusion has arisen or is likely to arise under this head.

Of course I am writing solely from the constructive engineer's point of view, and it may be here observed that practicians who write on questions of construction are likely to adopt the language they have found most useful, whatever new names may be invented by the physicists. Probably Mr. Evershed would not give up his "thoms," nor Mr. Kapp his "English lines," nor the writer his "ampere-turns" without a pang. Again, it is unlikely that anything the practician urges will be considered by the high-and-dry theorist, for the latter seldom understands the mode of thought of the former, and when he does comprehend, he fails to appreciate it.

Probably all engineers do not share my views, but the engineers—I bar *electricians*—who are represented as thirsting for fresh units I have never met. We have done wonderfully well for some time with the existing terminology, and the "swallowing of camels," to use Mr. Heaviside's expression, has not impaired our faculties. By all means let the "scienticulists" invent units and names for units, as many as they please, but they should not delude themselves into the idea that the practician is benefited thereby; it makes not the slightest difference to him.

I understand Mr. Heaviside is the ringleader of the unit movement, and for that gentleman's work I have the greatest respect. But as the heavens are higher than the earth, so are Mr. Heaviside's thoughts loftier than those of a mere practician, and his conclusions correspondingly obscure to the average intelligence. Nevertheless in his own domain he has done work which will endure. And conscious that the practician can never degrade it by application to dynamo design or other things useful, he ought to be both proud and happy.—Yours, &c., W. B. Esson.

London, August 27, 1895.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I am ashamed to say that for many years I designed dynamos without using the orthodox **H** and **B**, until the sarcasm of a third-year student, who wasted hours in drawing the most beautiful German capitals, at last induced me to multiply my square inches by 6·45 and my minutes by 60. It looks better, but it is more trouble.

As to the new units, they should certainly have the same relations to each other as the volt, ampere, and ohm; this will remove a great difficulty from the path of many students who have to teach themselves, and who always seem to find it so hard to get beyond Ohm's law. I do not see that any other units are wanted.

With regard to the 4π question I do not think that it is generally known that 2 **H** = the ampere-turns per inch long within 2 per cent. This is immensely useful, as all lengths can be taken in inches, so that I should be very sorry to see 4π disappear.

I hope that "thom" will not be adopted among the new names; it is nearly as offensive as "practician."—Yours, &c.,

110, Cannon-street, E.C., Henry W. Ravenshaw.

August 26, 1895.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: So long as the unit of length of the mechanical engineer is not a centimetre, it is unreasonable for us to reckon lengths and areas in machine designs by that unit. Conversions of the dimensions in a design from centimetres into inches are a serious nuisance, which an engineer cannot afford to submit to merely in order to support a theoretical system of measurements. Hence I consider the units for magnetic quantities per centimetre (**H**), or per square centimetre (**B**), and consequently the names for such units, as of little interest (What about a name for the unit of current density in amperes per square centimetre?) until the mechanical engineer takes to the centimetre, or, let me say, until he decides whether he will have that unit of

Digitized by Google

length or not. For, suppose the electrical and mechanical engineers, whilst waiting for the millenium of metrical measurements, were to agree upon, say, a decimal foot (10 English inches) and 1lb. avoirdupois as fundamental units, then they might any day, *without changing tools and gauges*, have the immense advantages accruing from the use of a rational system—advantages which otherwise seem to be still in the blue. It must be remembered that the C.G.S., besides having unsuitable fundamental units, is not a rational system.

I have a number of years ago constructed my **B-H** curves and tables with 1 kilo C.G.S. per square inch as unit **B**″, and 1 ampere-turn per inch as unit **H**″. With these units wrought iron and dynamo steel goes in the habitual ranges from 30 to 120 **B**″ under 3 to 570 **H**″, and the net magnetic pole in a dynamo, when it is running light, is (1 kilo C.G.S. being unit magnetic pole) $m = \frac{6 \times 10^6 E}{N h}$ (m = magnet pole, E = volts, N = revolutions per minute, C = number of bars effective), which are convenient values.

My **H**″ unit, 1 ampere-turn per inch, being $\frac{0 \cdot 4\pi}{2 \cdot 54}$, and my **B**″ unit $\frac{1,000}{2 \cdot 54^2}$ times greater than the respective C.G.S. units, my ratio $\frac{B''}{H''}$, multiplied by $\frac{1,000}{0 \cdot 4\pi 2 \cdot 54}$, or 313·3, brings μ based upon unity for air; my quantities are those given in practice. If we use the C.G.S. system, the practical data are ampere-turns per centimetre and pole (or lines) per square centimetre, and μ is obtained by multiplying their ratio by $\frac{1}{0 \cdot 4\pi}$, or 0·7958, a figure which is no more convenient than my 313·3.—Yours, &c.,

F. V. Andersen.

14, Westdown-road, Catford Bridge, London, S.E., August 27, 1895.

BRITISH v. CONTINENTAL TELEPHONY.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I was pleased to notice that Mr. G. L. Addenbrooke, in your issue of August 16th, has, with the help of figures taken from my recently-published book on "Continental Telephony," pointed out, in a manner which you, in your leader, justly commend, that one of the most persistently-advanced excuses for high telephone subscriptions in this country is devoid of foundation. For many years the shareholders of the National Telephone Company, Parliamentary Committees and the general public have been told that one of the chief causes of high rates is the much greater cost of labour of all kinds in this country. That this is not the case was one of the facts my book was designed to prove, and Mr. Addenbrooke has very neatly clinched the demonstration.

While admitting as much in your leader, you say "it is for him or others to prove that the cost of erecting, maintaining and working a telephone system is in the same state, that the Continental concerns honestly pay their way and something over." Now the lowest rates on the Continent are nearly invariably granted by companies who issue detailed and clear accounts at regular intervals; and had Mr. Addenbrooke dipped deeper into my book when reviewing it, he would have found that particular care had been taken to prove the very thing that you infer still calls for proof. Translations of the recent accounts and balance-sheets of several Continental companies are given in full, and these show conclusively that dividends even better than those habitually paid by the National Telephone Company are earned year after year on subscriptions which the Directors of the National Telephone Company have on numberless occasions stated to be ridiculous and unworthy of serious notice; and this after providing (which the National Telephone Company has never done) sickness and accident funds for the benefit of the male and female employees, and after putting aside adequate provision for deterioration and renewals. These accounts show that low subscriptions pay handsomely in exchanges larger than any possessed by the National Telephone Company, as well as in medium-sized and small towns. It is fortunate that these companies' accounts exist, since the various States adopt methods which render it impossible for an outsider to tell whether their systems are remunerative or the reverse.

If Mr. Addenbrooke cares to search even deeper within the book, he will find several other pet illusions and excuses effectually disposed of.—Yours, &c.,

A. R. Bennett.

22, St. Alban's-road, Harlesden, N.W., August 22, 1895.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

SPECIAL NOTICE.—The 1895 (thirteenth) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. In addition to the old well-known features of the book, which are brought up to date, a quantity of new and useful matter has been added, rendering the book more than ever indispensable to the Electrical, Engineering, and Allied Trades. Price, 7s. 6d., post free 8s. 3d., abroad 9s.

The following New Books and Editions of "The Electrician" Series *can be obtained of the Booksellers or direct from the Publishing Offices:—*

Laboratory Notes and Forms.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett (*now ready*). Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"Electric Lamps and Electric Lighting," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

A Large-Sheet Table, giving full particulars of the Electricity Supply Stations throughout the Kingdom, can now be supplied mounted on stout board, with cord for hanging. Price: Varnished, 3s. 6d.; Unvarnished, 3s. —each post free. A Map showing positions of Supply Stations throughout the country is mounted on the back of the Table, and a Coloured Map of Metropolitan Electric Lighting Areas and a large sheet of Electricity Supply Statistics are also mounted on some copies, the price of which complete, post free, is 5s.

A Sheet Table showing Total Capital Outlay and Receipts and Expenditure for the year 1894 of the Statutory Electric Supply Undertakings of the Metropolis is now ready, printed on thick paper, price 6d. each.

A Sheet Table giving similar particulars in relation to Provincial Statutory Electric Supply Undertakings is now ready, printed on thick paper, price 6d. each.

"The Work of Hertz."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"Electric Motive Power."—A new work, by Mr. Albion T. Snell, with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"Electrical Engineering Formulæ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"Drum Armatures and Commutators."—By Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"The Incandescent Lamp and its Manufacture."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application

"Practical Notes for Electrical Students."—By Messrs. A. E. Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

"The Art of Electrolytic Separation of Metals."—A second issue of Dr. Gore's book is now ready, price 10s. 6d. post free.

Tenders Invited.—Tenders are invited by the Vestry of Hammersmith, London, W., for complete schemes for public and private lighting, and for the supply of motor power in the compulsory area of the Vestry's Provisional Order. Particulars can be obtained of Mr. H. Mair, Surveyor to the Vestry. Tenders have to be sent in by 6:30 p.m. of *Wednesday next*, Sept. 4th.

Digitized by Google

TENDERS INVITED.—The Urban Sanitary Authority of the Borough of Bedford requires tenders for the supply of vulcanised rubber cables. Tenders to Mr. T. S. Porter, Town Hall, Bedford, by Wednesday next.

——— The Municipal Authorities of Braila, Roumania, invite tenders for the concession for (*a*) lighting about 64 kilometres of public streets by both electricity and gas, and (*b*) 64 kilometres of public streets by electricity alone, and also for the concession for the construction and operation of a network of electric tramways in the principal thoroughfares. Tenders to the Maire, Hôtel de Ville, Braila, by October 2nd.

——— The Urban Sanitary Authority of Chepping Wycombe (Bucks.) invite tenders for working their Provisional Electric Lighting Order. Tenders, by noon of October 14th next, to the Town Clerk, High Wycombe.

——— The Queenstown Town Commissioners require tenders for the erection of works and the necessary plant for generating electric current for the public and private lighting of the town. Tenders to be in by September 26th.

——— The Staffordshire County Infirmary Committee require tenders for wiring and fitting up the Infirmary for the electric light. Specifications, &c., may be had at the Infirmary and at the offices of the engineers (Messrs. Kincaid, Waller and Manville), 29, Great George-street, London, S.W. Tenders, addressed to the Secretary (Mr. Ellis E. Crisp), County Infirmary, Stafford, must be in by noon on Saturday, September 14th. Some additional information appears in our advertisement pages.

——— The Baths Committee of the Oldham Corporation invite tenders for supplying and fixing wires, fittings, &c., for lighting a portion of the Central Baths, Oldham, by electricity. Specifications may be had from the borough electrical engineer, Mr. S. Willmott Newington, and tenders, addressed to Mr. A. Nicholson, Town Clerk, Town Hall, Oldham, must be in by noon on September 11th. Further particulars are given in our advertisement columns.

——— The Portuguese Posts and Telegraphs Department require tenders for the supply of 19½ tons of iron and steel wire (from 1mm. to 4mm. dia.) and 2½ tons of bronze wire. Tenders by Sept. 4th to the Director General of Posts and Telegraphs, Lisbon.

——— The French Posts and Telegraphs Department requires tenders for the supply of 100 tons of copper wire and 24,000 copper cylinders. Tenders by September 10th to the Direction Générale des Postes et des Télégraphes, 103, Rue de Grenelle, Paris.

——— Tenders are invited by the municipal authorities of Jerez de los Caballeros (Badajoz), Spain, for the supply and erection of the necessary plant for the electric lighting of the town. Tenders to be addressed to the Ayuntamiento de Jerez de los Caballeros (Badajoz).

——— The Spanish Posts and Telegraph Department invites tenders for the supply of 20 tons of sulphate of copper and 12,000 zinc cylinders for telegraph purposes. Tenders to the Direccion Generale de Correos y Telegrafos, Madrid.

——— The Corporation of Sunderland invite tenders for (*a*) high-tension and low-tension concentric cables, (*b*) cast-iron pipes and box frames and covers, (*c*) stoneware casing, boxes, and bell-mouth protectors; (*d*) high-tension transformers for alternating current, and (*e*) meters for alternating current. Specifications may be obtained from the Borough Electrical Engineer (Mr. C. S. Vesey Brown), Electricity Supply Station, Sunderland. Tenders must be in by 6:30 p.m. on Friday, September 13th. Some further particulars appear in our advertisement columns.

TENDERS ACCEPTED.—The following tenders have been received for wiring and supplying the necessary fittings for the electric lighting of the County Council Offices, St. Mary's Gate, Derby, to the specification of Mr. J. Somes Story, M.I.C.E., architect and surveyor to the County Council. Current is to be taken from the Corporation mains:—

Fletcher and Hirst, Burnley (*accepted*)	£397	0	0
J. Davis and Sons, Derby	600	0	0

S. J. Waring and Son, Liverpool	475	0	0
B. Verity and Sons (*withdrawn*)	431	0	0

——— The Belfast Town Council have accepted the tender of Messrs. Wormald and Co. for covering the exhaust pipes at their electricity works.

SALE.—Our advertisement columns contain particulars of some high-class second-hand electric lighting machinery for disposal. The plant includes two 12 H.P. Davey-Paxman steam engines and boilers, two Crompton and two Edison-Hopkinson dynamos, a Crompton-Willans direct-coupled steam dynamo, two 40 H.P. Davey-Paxman locomotive boilers, a switchboard, and a battery of Crompton-Howell cells, together with feed-water injectors, beltings, steam pump, &c. Further information and orders to view may be had from the Hove Electric Lighting Company, Mansion House-buildings, London, E.C., or Cromwell-road, Hove.

BANKRUPTCY.—The following is a list of some of the creditors in the bankruptcy of Ronald A. Scott, lately carrying on business as an electrical engineer at Acton Hill:—

Fraser and Fraser	£50	0	0	Archdale (J.) and Co., Birmingham	£333	0	0
Gapp Bros.	86	0	0	Hill & Smith, Brierley Hill	12	3	8
General Electric Co.	12	2	3	Glover (W. T.) and Co., Salford	29	9	0
Highton (E. G.) & Co.	1,143	0	0	Colver Bros., Sheffield	21	15	0
Lloyd and Lloyd	12	5	0	Fully-secured creditor	4,180	0	0
Reeves and Son	100	0	0	Partly-secured creditor (Brecks, C.W.), Brough	2,775	0	0
Taylor and Hobson	51	10	0				
Willcox (W. H.) & Co.	12	16	8				
Farquharson, J.	1,060	0	0				
All of London.							

LIQUIDATION.—Last week an application by Mr. J. L. Fuller, electrical engineer, of Bush-lane, Cannon-street, London, E.C., for the compulsory winding-up of the New British Electrical Installation Contractors (Limited), was heard at the Worcester County Court before Sir R. Harington. Mr. Bell, who appeared for the petitioner, stated that the Company were indebted to creditor in the sum of £85. The old British Installation Company had a capital of £20,000, but upon the shares taken up only £1,075 had been subscribed. The new Company purchased the business of the old Company for £3,000, for which amount Six per Cent. Debentures were created in favour of the old shareholders as supplementary capital. In July last, on the application of the debenture-holders, who claimed the whole of the assets of the Company, Mr. Justice Kekewich appointed a Mr. H. A. Leicester receiver for the debenture-holders. The petition alleged that the old Company was insolvent and its shares valueless. After a patient hearing the judge made an order for the compulsory winding-up of the Company, and appointed the Official Receiver liquidator.

——— An application was made to Mr. Justice Mathew on Tuesday in the Chancery Division to sanction a scheme of arrangement by which the Otis Steel Company (Limited) could be got out of liquidation. Meetings of the shareholders had been held, and had approved of the proposed arrangement, the new company to take over the liabilities of the old. His Lordship granted the application, subject to a report from the Registrar that no meeting of creditors was necessary.

INFORMATION INVITED.—A correspondent of the *Financial Times* pertinently (perhaps we should say impertinently) desires to know something of the details of the winding-up of Messrs. J. E. H. Gordon and Co. (Limited). The correspondent appears to think this information is somewhat overdue. There are, however, other liquidations regarding which some information would be appreciated. A very long time back a concern called the Electrical Engineering Corporation (Limited) reached the winding-up stage after a tortuous career. We have ourselves made several attempts to obtain information, for our own and our readers' benefit, concerning this liquidation, but particulars are very difficult to obtain. Some information relating to the affairs of Poole and White (Limited), of J. G. Statter and Co. (Limited), and of several other concerns would be welcome. Perhaps some of the gentlemen who figured conspicuously in these concerns would volunteer some information, which, we feel sure, would be received with thanks.

APPOINTMENT VACANT.—The Portsmouth Town Council require a clerk of works to superintend the laying of conduits, &c., in connection with their electric lighting extensions. Salary £2 per week. Applications to the Chairman of the Electric Light Committee, Gunwharf-road, Portsmouth, by Thursday next, September 5th.

PARTNERSHIP.—Messrs. Percy H. Tewson and Roland H. Streatfield have entered into partnership, and will carry on business as electrical engineers and contractors under the style of Tewson and Streatfield, at 35, Bucklersbury, London, E.C. Both members of the firm were formerly with Messrs. Laing, Wharton and Down.

DISSOLUTIONS OF PARTNERSHIP.—Messrs. Dadge and Fraser, carrying on business as electrical engineers under the style of Dadge and Co., at 18, Cecil-court, Charing Cross-road, London, W.C., have dissolved partnership.

——— Messrs. Broadbent and Reaney, electrical and mechanical engineers, 80, Manningham-lane, Bradford, have dissolved partnership.

——— The partnership business of mathematical instrument makers hithero carried on by Messrs. W. E. and C. Barker, under the style of Francis Barker and Son, at 12, Clerkenwell-road, London, E.C., has been dissolved.

CHANGE OF ADDRESS.—Until further notice the Glasgow address of the Eastern Telegraph Company is changed from 5, Royal Bank-place, to 141, Buchanan-street.

PERSONAL.—Mr. R. S. Bozon, who has for some time past been in the service of the Post Office at Birmingham, has been appointed

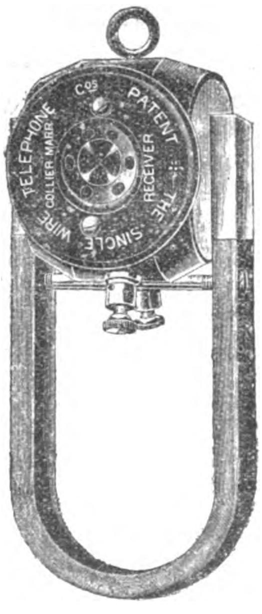
Digitized by Google

electrical engineer at the Palace Theatre of Varieties, London. Before his appointment to Birmingham Mr. Bozon was engaged at Brighton, and he was for some years in the States.

Dividend.—A final dividend on the shares of the International Cable Company (Limited) (in liquidation), at the rate of 5s. 3¾d. per share, has been declared, and is now payable at the Offices of the Official Liquidator (Mr. F. S. Lucey), 15, George-street, Mansion House, London, E.C.

Hermite Sanitation Plants.—Messrs. Paterson and Cooper have received instructions from the War Office Authorities to proceed with the erection at Netley Hospital of the Hermite Sanitation Plant, the cost of which has been provided for in this year's parliamentary estimates. The Corporation of Cape Town have also ordered a plant for producing electrolised sea water, with a view to the Hermite process being applied to the sanitation of Cape Town.

The Collier Receiver.—The accompanying illustration shows the latest form of the Collier receiver, the patent rights in which have been acquired by the Single-Wire Multiple Telephone Signal Company (Limited), of 50, Old Broad-street, E.C. The instrument has been before the public for some years, but has not, in the opinion of those who know it best, yet received the attention it deserves. The Company claim that it is without doubt the most sensitive, loudest and clearest telephone receiver in the market, and where, from any cause, the currents available to operate the receiver at the end of a telephone line are much reduced this form of receiver has very great advantages, and will enable communication to be kept up. The only objection that could, in the Company's opinion, be formerly urged against it was its outward appear-



ance, which has, however, now been modified as shown. The extreme sensitiveness of these instruments is due to two causes : (1) the use of two diaphragms arranged in combination with a specially-shaped air chamber, so that each reinforces the sound waves produced by the other ; and (2) the fact that the magnetic polarisation, owing to the special arrangement by which the lines of force are carried through almost a closed circuit of thick iron all the way, is exceptionally strong ; and, the coil being placed centrally on a short, well-laminated core, and not touching a mass of iron or steel at either end, but always well polarised, the power of the high frequency but minute undulatory currents is exceptionally well conserved and reconverted into the form of energy required. This receiver is, therefore, especially adapted for long-distance work. In conjunction with a Brown transmitter, also owned by the same Company, excellent results have been obtained. As showing one of many instances where the receiver has been found superior to others, the owners state that all the best receivers to be obtained have been tried by Mr. Pocklington, representative of Callender's Company at Liverpool, for detecting faults in electric light leads. He says : "In my opinion your telephone receivers are by far the best I have yet tried for localising faults on underground mains, such as those in Liverpool. My experience extends over some seven years, and I have never been so certain of localisation with any other make." The combined Collier receiver and Brown transmitter telephone set is supplied by the Company specially made for warehouse, factory, and office requirements. The usual bell is dispensed with, and its place taken by the spoken word—a very useful and compact arrangement, requiring only very simple connections and minimising the cost of wiring.

Cable-Making and Wire-Covering Machinery.—Messrs. Johnson and Phillips have wisely entered at Stationers' Hall a very complete catalogue of machinery for sheathing, armouring and serving submarine cables, and also machinery for wire-winding, stranding, and closing work for electric light cables. The catalogue is very fully illustrated, and is undoubtedly the completest of the kind yet published by manufacturers of this class of machinery. The illustrations are taken from photographs of the actual machines which are the outcome of long experience in this special department. The firm are not only manufacturers but users of these machines, and the experience gained, therefore, is first hand. Accompanying the particulars are what may be termed guarantees of the output of the machines. The particulars given are very full and complete, and comprise the sizes, capacity and dimensions over all in English and in metrical measurements. The makers especially call attention to the machine illustrated on page 2, which is for sheathing "shore-ends," and is probably the largest of its kind in existence. It will armour the heaviest types of submarine cables, and at the same operation will sheath with tapes and "compound," or can be made to sheath with steel tapes or hemp yarns. This particular machine has been in work in the factory of one of the chief Continental manufacturing firms for several years, and has given every satisfaction. Messrs. Johnson and Phillips refer with some pride to the capacity of their works at Old Charlton for turning out machines in cases of emergency, a case in point being the execution of an order for 25 machines, illustrated on page 16 of the catalogue, in the short time of seven weeks. The capacity of these machines was 750 miles of covered wires per day. Many of the machines illustrated in the catalogue are of novel design, and no previous particulars have appeared regarding them. A further catalogue is in course of preparation, and will comprise machines for core taping, core vulcanising, cotton covering, indiarubber covering, silk coverings. The firm offer copies of the catalogues, compounding, &c. to any responsible applicant. It should be added that a comprehensive index, and the notes concerning the use of the machinery, make the catalogue unusually compact and complete.

College Calendars.—We have received from Messrs. Whittaker and Co. a copy of the "Programme of the Technological Examinations of the City and Guilds of London Institute" for the Session 1895-6." The price of the programme is 10d. net. Very full particulars will be found, in some places illustrated, of the subjects to be taken during the ensuing session. From the Durham College of Science we have received a calendar for the session 1895-6, together with prospectuses of the day and evening classes. Connected with this College there is also special Saturday classes for the benefit of artisans. The Secretary of University College, Bristol, forwards a copy of the calendar for the coming session, in which all particulars relating to the classes will be found. Copies of this Calendar can be obtained of Messrs. Whittaker & Co.

Barnet.—A belated attempt by Mr. Bampfield to infuse interest into the electric lighting question in this town, has signally failed—for the want of a seconder. The question arose on the discussion of correspondence between the District Council and Messrs. Vaughan and Brown.

Birmingham.—Col. W. L. Coke, M.I.C.E., held a Local Government Board inquiry on Tuesday into an application by the City Council to borrow £27,420 for technical education purposes. It was stated that the Council had already expended over £61,000 in purchasing a site for the technical school, erecting buildings, &c. The school was now nearing completion, and £14,000 of the loan was required for fitting up 116 rooms, laboratories, &c. The contract for supplying the fittings had been placed with Thomas Parker (Limited) for £13,227, and this work was in progress, because the Committee considered it desirable that the new session should be commenced next month. There was also a sum of £6,080 wanted for lighting the school by electricity, and for providing electric motive power in the laboratories. There was no opposition to the application.——The electric light is making steady progress in this city. The Birmingham Electrical Supply Company are laying mains in Broad-street and Hagley-road. Several residences in the Edgbaston district are being wired and fitted, and it is stated that current will be available by the end of next month. It is also stated that in order to cope with the growing demand for current in Newhall-street, the centre of the jewellery trade, the Company are building another supply station in that street.

Blackpool.—The Electric Lighting Committee of the Town Council, at their meeting on Saturday last, decided to recommend the Council to spend £30,000 in extending the Corporation electricity works before next season. Two new boilers and two 300-kilowatt machines will be erected. This addition to the plant will involve large extensions of the buildings. The question of transferring the tramway generating plant to the new buildings has been deferred. If the recommendation of the Committee be adopted the total expenditure on the electricity works will amount

Digitized by Google

to nearly £90,000, but the Committee think the demand for current amply justifies the new expenditure. This demand continues to grow by leaps and bounds, and there is already considerable difficulty in complying with customers' requirements.

Bristol.—At the last meeting of the Electrical Committee it was decided to recommend the extension of the electric light mains from the corner of Regent-street to Victoria-square; from the end of West-street, St. Philip's, along Trinity-road to supply the new free library and St. Philip's police station; a short distance in Redcliff-street; from Redland Park-road to a part of Hampton-road, and a short distance in St. Paul's-road. The consideration of a proposal to include Cotham in the present extension scheme was postponed, as the Committee have already practically expended the money at their disposal. The demand for current continues to increase in a most satisfactory manner. The Guildhall and the Prince's Theatre are being wired and fitted for the electric light.

Bromley (Kent).—The District Council some time ago received an offer to purchase their Provisional Electric Lighting Order, and at the last meeting the Chairman (Mr. W. H. Bosanquet), in reply to a question as to what progress had been made, said that the Committee dealing with the question were making inquiries as to the ability of those who proposed to purchase the Order to carry out its provisions, and when this point had been satisfactorily settled the Committee would present a report to the Council.

Cambridge.—The present contract with the local gas company for lighting the streets expires in June, 1896, and, on the recommendation of the Paving, Drainage and Lighting Committee, the Town Council have decided to give the Cambridge Electric Supply Company an opportunity of tendering for the lighting of the town.

Cheltenham.—The Public Library is now lighted by electricity, the current having been switched on for the first time on Monday last. The work of wiring and fitting up the library has been carried out by Messrs. R. E. and C. Marshall to the specification of the borough electrical engineer, Mr. Hamilton Kilgour; 141 incandescents, with a total of 2,712 c.p. are used.

Church Lighting.—Lindley Parish Church, Huddersfield, and Zion Chapel, Lindley, are to be lighted electrically.—It has been decided to light the Congregational Church, Buckley (North Wales), electrically.

Club Lighting.—The West and Pellon Wards Liberal Club, Halifax, is now lighted electrically. The work of installation has been carried out by Messrs. Nunn and Sykes, of Halifax.

Dundalk.—The Electric Lighting Committee have just presented a report on the question of the introduction of the electric light into the town. The report recommends that in order to comply with the Provisional Order (which expires in July, 1896) the Council should invite electric lighting contractors to tender for the lighting of the town under licence, failing which steps should be taken in November next to give more extensive powers than a licence to the proposed contractors. The report was unanimously adopted.

Durban.—The Town Council have unanimously decided to adopt the recommendations contained in the report of Mr. W. H. Preece and Mr. James Fletcher (borough engineer) on the question of the electric lighting of Durban. The cost of the initial installation is not to exceed £25,000, and it was also decided to prepare specifications and invite tenders from the principal British manufacturing firms for the supply and erection of the necessary plant. An abstract of the report appeared in our issue of May 31st last.

Electric Traction in Egypt.—In reference to our Note on this subject in our last issue, we now learn that the Société Anonyme des Tramways du Caire, the company which was recently formed to take over the concession for the erection of electric tramways in Cairo, has given the contract for the construction and equipment of the line to the Union Elektricitäts Gesellschaft of Berlin.

Electric Railways.—Mr. Charles Rettie, of Liverpool, communicates to the *Journal of Commerce* of the 27th inst. on the subject of electric railways in general, and in connection with the application of electricity to the Mersey Company's line in particular. In taking a survey of the applications of the electric system to railways, Mr. Rettie observes that there is a splendid opening on the Lancashire and Yorkshire Company's 18-mile run to Southport for the application of the electric system.

Exeter.—A special meeting of the City Council was held on Wednesday to consider the advisability of negotiating with the Exeter Electric Light Company (Limited) for the acquisition of the Company's undertaking. A letter received by the Town Clerk from the solicitors to the Company stated that the County of London and Brush Provincial Company had offered £7,000 for their undertaking, and a syndicate of local gentlemen offered to give over £8,000. The critical condition of the Company rendered it necessary that an immediate decision should be come to, and if the Council were willing to purchase for £10,000, the Directors would recommend the proprietors to accept that amount. A memorial from the principal tradesmen in High-street, Fore-street, and Queen-street had also been received in favour of the acquisition of the works by the Council, and the Deputy-Mayor (Mr. E. J. Domville) said that he called the meeting in response to an urgent requisition. After referring to the position of the Company, he moved that the whole matter be referred to a special committee, but this motion was withdrawn in favour of a resolution by Mr. W. Wreford declaring it to be expedient that the control and supply of the electric light should be in the hands of the Council. A long discussion on this proposition took place. Mr. Penny thought if the Council let the present opportunity of purchasing the Electric Light Company's works pass by they would be making a mistake. The motion was unanimously adopted, and a further resolution by Mr. Wreford, authorising the Council to enter into negotiations with the Company for the acquisition of their undertaking, was also adopted. The further consideration of the matter was then referred to a committee of the whole Council, with power to appoint a special committee to decide points of detail.

Faraday.—An excellent portrait of Michael Faraday is published with the *Electrical Journal* of Chicago, U.S.A., for August 15th.

German Foresight.—At the instigation of the German Envoy at Tokyo and of the Prussian Minister of Commerce, a committee of German manufacturers have resolved to publish a periodical in the Japanese language, with the object of bringing prominently before Japanese buyers the goods of German firms. It has also been decided to publish a similar periodical in Chinese, and it is probable that the necessary translations will be made by the teachers of Japanese and Chinese in the Oriental Seminary at Berlin.

Hampstead.—The Electric Lighting Committee of the Vestry have recently presented a report, in which they review the past history of the station in Lithos-road, the foundation stone of which was laid in May, 1894. Reference is made to hitches which have from time to time occurred, but which have been overcome. Until now the lighting is a complete success. This is especially the case with private lighting, which in March last reached the equivalent of 6,500 8 c.p. incandescents. Since March the number of customers has risen to 116, with an equivalent of 11,879 8 c.p. lamps connected. Considerable additions are being carried out, and applications for current justify the Committee in seriously considering still further extensions. Rebates to large consumers from 3 to 20 per cent. have been agreed upon, to be made on the Christmas quarter accounts. A report is to be issued at Christmas on the general working of the station from the opening up till that time, to be published with the usual accounts of the Vestry's electric lighting undertaking.

Hull.—At the last meeting of the Electric Lighting Committee of the Town Council the Sub-committee recently appointed to consider the question of the appointment of a Borough Electrical Engineer in place of Mr. A. H. Gibbings, who has been appointed to Bradford, reported that they had interviewed Mr. Gibbings and Mr. Bastow (assistant engineer) in reference to filling up the vacancy. Mr. Gibbings' view was that Mr. Bastow had not had sufficient experience to justify his appointment to take charge of the station. A discussion on this report followed, and Mr. Holder (the Chairman of the Committee) moved "That the appointment of an electrical engineer be left open for four months beyond the termination of Mr. Gibbings' appointment, and that Mr. Bastow be asked to take charge of the station for that period." This resolution, however, was not seconded, and it was decided to adopt the Sub-Committee's recommendation to advertise for an engineer, whose salary has been fixed £250 per annum. Applications have to be sent in by the 19th September to Mr. R. Hill Dawe, Town Clerk. It has also been decided to allow Mr. Gibbings to go to Bradford two days a week, as the Hull station work would permit, subject to the Bradford Corporation paying the Committee his rate of remuneration up to the termination of his agreement with Hull or to Mr. Gibbings foregoing such payment—a truly involved arrangement, and hardly worthy of the high contracting parties.

Kingswood (Bristol).—The Town and Village Electric Light and Power Company, who have taken over the electric lighting of this district, have made proposals to the District Council as to public and private lighting, and at the last meeting of the Council a committee was appointed to consider and report on the matter.

London General Omnibus Company.—At the meeting of shareholders yesterday, the Chairman, Mr. Alderman Pound, who is not unknown in the City of London in connection with electric lighting enterprise, stated that the Directors were closely watching the development of electric and oil motors as compared with horse power.

Metropolitan Telephone Exchanges.—The new Gerard-street (Regent) Exchange of the National Telephone Company is, we understand, to be opened on October 14th. The new exchange is made up of the old Regent-street exchange and a portion of the Chancery-lane subscribers; the remaining portion of the subscribers of the latter exchange being transferred to Holborn. We are

Digitized by Google

ourselves in the unsatisfactory predicament of having our telephone number changed, and can vouch for the inconvenience and expense which such a change involves. The National Company are face to face with a choice of evils, and have decided that the alteration of a great many subscribers' numbers is inevitable. It is to be hoped that arrangements are being made to obviate the necessity for any similar re-numbering in the future.

NEWPORT (MON.).—The Free Library Committee have referred the question of lighting the library by electricity to a Sub-Committee for consideration and report.

PORTSMOUTH.—The Town Council have decided to reduce the charge for electric current from 6d. to 5d. per unit, the reduction to take effect from September 29th. The Electric Lighting Committee are busily engaged in making extensions to the mains, and are introducing a new system of earthenware ducts, by means of which it is claimed the making of house connections can be effected at a cost of 1s. 6d., against 5s. previously.

THEATRE LIGHTING.—The new Empire Palace Theatre, Sheffield, is to be lighted throughout by electricity. The work of wiring and fitting has been entrusted to the Sheffield Electric Light and Power Company (Limited).

THE BERNE OFFICIAL VOCABULARY.—It is stated that the French Government has, on the representations of the London and Manchester Chambers of Commerce, suspended the order for the compulsory use from next New Year's Day of the Berne vocabulary for commercial telegrams. Previous protests from the Paris and Havre Chambers of Commerce had produced no results. It is also stated that the movement against the obligatory use of the vocabulary is rapidly spreading in other Continental countries.

THE LONDON TECHNICAL EDUCATION BOARD.—The issue of the *London Technical Education Gazette* for August contains particulars of the awards granted by the Board for the session 1894-95 to many of the schools of science, art or technology aided by the Board, and also the maintenance grants to the Polytechnics and to University College and Bedford College. The list of candidates who were recommended for evening exhibitions in science and technology contains a gratifying proportion of engineers' apprentices, draughtsmen, metal workers, and instrument makers. A list is given of 19 matriculation students of the Central Technical College of the City and Guilds of London Institute who have received the Board's diploma for applied physics and electrical engineering. The *Gazette* is a useful publication, and should become widely known.

WREXHAM.—The Board of Trade have decided to defer the consideration of the revocation of the Wrexham and District Electric Supply Company's Provisional Order for a further period of six months.

WORKS LIGHTING.—The extensive glass works of Messrs. Kilner Bros., at Conisborough, Yorks., are to be lighted throughout by electricity.

YORK.—The electric lighting question in this city has now taken a new turn. On the 12th inst. the Council referred back the whole question to the Streets and Building Committee, with instructions to select an expert to advise them as to the best system of electric lighting for the city, and the Committee have now resolved to invite Mr. Preece to become their adviser, and they have requested him to inform them what inclusive fee he would require to advise on the matter, and to support the application for the necessary borrowing powers, &c., to carry out the electric lighting scheme. It is to be hoped that Mr. Preece, if he accepts the position, will be successful in rescuing the electric lighting question from the involved condition in which it has been allowed to lapse by the combined action or inaction of the several committees who have in the past had the matter in hand.

OUTING.—The employés of the Edison and Swan Company's Ponder's End Works held their annual excursion at Brighton on Saturday last. The city offices and warehouses of the Company were closed for the occasion, and consequently many members of the City staff were enabled to join the party, which numbered upwards of 600. The excursionists were favoured with fine weather, and an enjoyable day was spent.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

August 19, 1895.

15,529. A. J. WHEATLEY. Harborne, near Birmingham. Improvements in electrical time switches.

15,547. J. A. KINGDON. London. An improved method of operating electric locomotives, tramcars, and the like, and apparatus therefor.

15,563. L. EPSTEIN. London. Improvements in the formation of the electrodes for use in primary and secondary batteries.

August 20, 1895.

15,664. SIEMENS BROS. AND CO. (LIMITED). London. Improvements in electrical apparatus for railway signals actuated by passing trains. (Messrs. Siemens and Halske, Germany.)

15,686. W. P. THOMPSON. Liverpool. Improvements in electric railways. (James Francis McLaughlin, United States.)*

15,695. E. J. CLUBBE and A. W. SOUTHEY. London. Improvements in electrically-propelled carriages.

15,703. G. G. M. HARDINGHAM. London. Improvements in electric cables. (The firm of Felten and Guilleaume, Germany.)

August 21, 1895.

15,722. W. THOMSON and W. ROUTLEDGE. Newcastle-on-Tyne. Improvements in the formation of thin plates intended to be subsequently assembled, as in certain electrical and like constructions.

15,736. W. PATTERSON. London. Improvements in insulating wire for electrical purposes.

SPECIFICATIONS PUBLISHED.

NOTE.—All Specifications can now be obtained at the uniform price of 8d. each.

1894.

8,607. THOMPSON (KEITH). Electrical exchanges.

15,004. RITTER. Telephonic installations.

17,130. STOTZ and SCHINDLER-JENNY. Electrically heating liquids.

17,335. GRAHAM and CHAPMAN. Governing dynamos, &c.

1895.

7,458. KELLNER. Electrolysis of metallic salts.

10,445. STÖRMER. Electrolysis of alkali salts.

12,161. MOULART. Electric conductors.

12,468. MÜLLER. Electric railways.

NEW COMPANIES, STATUTORY RETURNS, &c.

In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1895, pages *304-332, &c. &c.*]

FIELDING AND PLATT (LIMITED).—This Company was registered on August 24th, with a capital of £50,000, in £10 shares, to purchase and take over the business carried on under the style of "Fielding and Platt," of the Atlas Iron Works, Gloucester, to enter into an agreement with Messrs. James Platt and James and John Fielding, engineers, of Gloucester, and to carry on the business of general engineers, gas and oil engine makers, metal workers, boiler makers, &c.

F. MADELEY AND CO. (LIMITED).—This Company has been registered, with a capital of £5,000, in £5 shares, to purchase the business of a tube manufacturer, carried on by F. Madeley, at Watery-lane, Birmingham, and to carry on the business of manufacturers of brass, copper and other tubes, metal workers, ironfounders and machinists.

PORTABLE ELECTRIC LAMP COMPANY (LIMITED).—This Company was registered on August 26th, with a capital of £50,000, in £1 shares, to acquire from William and Andrew P. Morrison the benefit of an invention entitled "improvements in portable primary batteries," and the letters patent granted in respect thereof (No. 9,826 of 1894), also the benefit of an invention of a composition suitable for the manufacture of the cases of the said batteries, and of a chemical compound known as "electric sand," suitable for the generation of electricity, for use with the said batteries, and to manufacture, provide, sell, deal in and let on hire steam, gas and other engines, dynamo machinery, cables, wires, batteries, electric motors, miners' electric safety lamps, meters, instruments, fittings, and other electrical apparatus and appliances. The subscribers, with one share each, are: E. S. Walmisley, F. H. Sanders, E. F. Grainge, R. G. Taylor, A. M. Forbes, L. White, and J. Seagrave.

ROAD VEHICLE STARTER SYNDICATE (LIMITED).—This Company has been registered with a capital of £18,000, in £1 shares, to carry on business as merchants, patentees, manufacturers, agents, contractors, &c.

Digitized by Google

AFRICAN DIRECT TELEGRAPH COMPANY (LIMITED).—The annual return to August 7th has been filed. Out of a capital of £300,000, in £10 shares, 23,600 shares have been subscribed for and the full amount paid thereon.

ALTERNATE-CURRENT ELECTRO-MOTOR SYNDICATE (LIMITED).—The annual return to August 17th has been filed. The nominal capital is £6,000, in £1 shares; 5,037 shares have been taken up, and 2,000 have been issued as fully paid to Mr. W. Langdon-Davies electrical engineer. A call of 6s. per share on the remaining 3,037 shares has been made.

NEW ELECTRICITY SUPPLY COMPANY OF CROYDON (LIMITED).—The annual return for 1894 hast just been filed. The nominal capital is £40,000, in 100 Founders' and 7,900 Ordinary shares of £5 each; 29 of the former have been allotted.

PEARSON'S AUTOMATIC FIRE INDICATOR COMPANY (LIMITED).—The statutory return to July 12th has been filed. The nominal capital is £5,000, in £1 shares, of which 1,715 have been taken up; 1,000 fully-paid shares have been issued to Mr. Edward Mann, electrical engineer; 10s. per share has been called on 708 shares, but no calls have been made on the seven subscribers' shares.

RAND CENTRAL ELECTRIC WORKS (LIMITED).—The statutory return to August 13th has been filed. The nominal capital is £300,000, in £1 shares, of which 275,000 have been allotted, and a call of 5s. per share made.

READING ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return to July 1st has been filed. The nominal capital is £75,000, in £5 shares, and 2,819 of these have been allotted; 2,000 shares are held by Mr. J. C. Fiddler, merchant, Reading.

UNITED RIVER PLATE TELEPHONE COMPANY (LIMITED).—The annual return to July 23rd has been filed. Of a nominal capital of £500,000, in £5 shares, 58,000 shares have been taken up. 16,000 have been issued as fully paid, and the full amount has been called on the remaining 42,000 shares.

WESTERN COUNTIES ELECTRIC LIGHT AND POWER SYNDICATE (LIMITED).—The annual return to August 9th has been filed. The nominal capital of £25,000 is divided into 380 Ordinary and 120 Deferred shares, of £50 each. 85 of the former and all of the latter have been taken up. The Deferred shares have been issued as fully paid, and the full amount has been called on the Ordinary shares.

CITY NOTES.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver, 30½d. per oz. (Aug. 29th). Consols (2¾ per cent.) 107¾—107⅞ for money, 107⅞—107⅞ for September account (Aug. 29th); 2½ per cent. 106¼—106½. Stock Exchange Settling Days: Consols, Aug. 30th—Sept. 2nd; Stocks and Shares Continuation Day, Sept. 9th; Ticket Day, Sept. 10th; Pay Day, Sept. 11th; Mining Shares Carry-over Day, Sept. 7th; Railway and Foreign Stocks, &c., Sept. 10th—12th.

BRISTOL GAS COMPANY.—At the half-yearly meeting of this Company on Friday, the Chairman (Mr. J. W. S. Dix), in moving the adoption of the report and accounts, announced a further reduction of 2d. per 1,000 cubic feet in the price of gas. He said that the increase in their output (7½ per cent.), showed they were not much affected by their electrical friends, and the shareholders need not have any fear as to their not being able to maintain their present prosperous position. To properly appreciate the reduction and this heroic expression of opinion, our readers must remember that the Bristol Corporation are the owners of a thriving electricity supply station, and it will also be seen from another column that the Electrical Committee of the Corporation have decided to recommend considerable further extensions of the electric light mains.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended August 25th amounted to £875, and to £878 for the corresponding period of last year, a decrease of £3. The total receipts for the half-year were £6,883, and £6,941 for the corresponding period of last year, a decrease of £58.

CORK GAS CONSUMER'S COMPANY (LIMITED).—At the half-yearly meeting of the shareholders of this Company last week the Chairman (Mr. George Lynch) said that they had a considerable demand for gas from firms in the city who had private installations of the electric light, and he therefore thought that, instead of being a serious competitor, the electric light would prove of considerable service to them. This view was also echoed by Mr. S. H. Newsom. Answering a question as to the rumour of the formation of an electric light company, the Chairman said that the statutory notice of intention to apply for a Provisional Order had been given to the City Council. Mr. Denny Lane stated that similar notices had been served on three previous occasions, and added that he believed the Corporation were making inquiries from other Irish towns where the electric light has already been adopted as to the cost, &c., of an installation.

ELECTRIC CONSTRUCTION COMPANY (LIMITED).—The share transfer books of this Company will be closed to September 12th.

ELECTRIC TRACTION IN AMERICA.—It is stated that the Siemens and Halske Electric Company of America intend to form a combination with the Yerkes interest to fight the recently-formed Westinghouse-Baldwin combination. The Yerkes interests comprise the Widener-Elkins Syndicate, controlling many of the street car lines in New York, Philadelphia, Pittsburgh and Chicago. Mr. Yerkes, jun., was recently elected vice-president of the Siemens and Halske Company. Our readers will remember that in our issue of July 26th we gave particulars of the purchase of the plant of the Grant Locomotive Works in Cicero, Ill., by the Siemens and Halske Company, and at the same time the Siemens Company increased its capital from $1,000,000 to $2,000,000.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 25th inst. amounted to £1,318, and to £1,094 in the corresponding week last year, an increase of £224.

LONDON, DEPTFORD AND GREENWICH TRAMWAYS COMPANY (LIMITED).—At the half-yearly meeting of this Company on Tuesday the Chairman (Mr. W. J. Carruthers-Wain) very strongly condemned the action of the London County Council in connection with their treatment of the shareholders' interest. There was, he said, scarcely a project which the Council had formulated which would not in some way have damaged the interests of tramway companies, and he hoped that the Bill promoted by the Council to enable them to work all tramways (whether they leased the lines or not) would be strangled in the House of Lords.

NORTH STAFFORDSHIRE TRAMWAYS COMPANY (LIMITED).—The ordinary general meeting of this Company was held on Tuesday at the Guildhall Tavern, Gresham-street, London, E.C., Mr. W. J. Carruthers-Wain presiding. The Chairman said that not only would all obstacles to the working of the Longton lines be shortly removed, but the Longton Town Council are likely to make considerable extensions to the lines at their own expense. Their licence for working the tramways by steam expired in May, and it was suggested to them that they should take into consideration the question of the adoption of some improved motor. Having regard to the severe gradients in North Staffordshire, there could be no doubt that there were only two systems of traction that could possibly be adopted, and these were cable or electricity by means of overhead wires. The traffic was not great enough for the former system, and, in addition, the curves are tremendous. Consequently, the Directors have been compelled to consider the overhead system of electric traction, and therefore suggested to the Town Council that, if they desired them to adopt electricity, they should grant them an extension of their lease in order that they might be able to recoup themselves for the additional cost of introducing a new system of traction. The Town Council had replied that if the Company introduce electric traction they are prepared to considerably extend the present lease. The Chairman announced that a proper scheme for the working of the line by electricity had been prepared, and when all the necessary preliminary arrangements had been made by the local authority he would lay the details of the proposal before the shareholders.

PHOSPHOR BRONZE COMPANY (LIMITED AND REDUCED).—Notice is given that the Order of the Chancery Division of the High Court of Justice, dated July 20, 1895, confirming the reduction of the capital of this Company from £150,000 to £90,000 (in 15,000 Preference and 15,000 Ordinary shares of £3 each), and the Minute showing the several particulars respecting the altered capital were registered by the Registrar of Joint Stock Companies on August 17th inst. Only 8,375 Preference and 7,335 Ordinary shares have been issued, and on each £3 per share has been paid.

SOUTH STAFFORDSHIRE TRAMWAYS COMPANY.—The annual meeting of this Company was held on Monday last at the Cannon-street Hotel, Mr. W. S. L. Schuster presiding. The Chairman said the present Directors were only responsible for the management of the Company's business for six weeks out of the period under review, and had repudiated the contract made with the Electric Construction Company by the late Directors, on the ground that it was not an equitable one, and that no Court would uphold it. This contract provided for a payment of 9d. per mile to the Electric Construction Company. The working expenses of the tramway amounted to about 2½d., which gave a total of 11½d. The receipts were, roughly, 10d., and therefore there would be an actual loss of 1½d. per mile, or £1,500 a year under that contract. Law proceedings with the Electric Construction Company in reference to the matter were still pending. He considered the contract meant absolute ruin to the South Staffordshire Company, and they were advised that its terms could not be enforced. The present Directors had resisted all attempts to break up their undertaking, and the Court had so far supported their action. As to the question of reorganisation, the Chairman said they had abolished the offices of traffic superintendent and draughtsman, while they had appointed Mr. Robins to the position of manager in place of Mr. A. Dickinson. In order to improve the service on the electrical section of the tramway the Company have decided to run trains every 15 minutes from Wednesbury to Bloxwich, and every half hour from Darlaston to Mellish-road, Walsall. After a long discussion the report and accounts were adopted.

STOCK EXCHANGE NOTICES.—Application has been made to the Stock Exchange Committee to appoint a special settling day in, and to grant a quotation for 17,139 "A" shares (Nos. 01 to 05,800 and 05,802 to 017,140) of the Edison and Swan United Electric Light Company (Limited).

WEST AFRICAN TELEGRAPH COMPANY (LIMITED).—The half-yearly interest, due September 1st, on the Five per Cent. Mortgage Debentures of this Company, will be paid on and after Monday next by the National Bank of Scotland, 37, Nicholas-lane, London, E.C.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the week ended August 23rd, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), amounted to £2,945.

WESTERN UNION TELEGRAPH COMPANY.—A Company with this title, and having a capital stock of $100,000, has recently been incorporated at Chicago. The promoters say it will be able to provide exchange connections for subscribers at $30 per annum.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 903. [No. 19. Vol. XXXV.] FRIDAY, SEPTEMBER 6, 1895. PRICE SIXPENCE.

NOTES.

THOUGH Ipswich is, of British Association centres, an unusually small town; and has the distinction of being the place at which the smallest meeting of the Association has ever been held, save that at the start at York; we may expect that the activity at Ipswich during the forthcoming meeting will be little if any below the average. The interests of electrical men centre in the Mechanical, Physical and Chemical Sections, and in the combined meetings of these Sections which at Oxford proved so successful.

IN Section A, which is devoted to mathematics and physics, a good initial interest will be created for theorists by the presidential address from Prof. W. M. HICKS, on the present development of the vortex atom theory and kindred hypotheses of an elastic fluid ether. On the following day this same Section will conjoin with Section B, the province of which is Chemistry, to consider the relation between the elementary state of a molecule and the complexities of its spectrum, a subject to which we made some reference last week. Another discussion, on the adoption of a new unit of heat—do we want one? we wonder—has been arranged, and will be opened by a Paper from Mr. E. H. GRIFFITHS. Sectional Papers on a diversity of topics will be brought forward by a great many well-known men, and particulars of these will be found in our news "Notes" this week.

THERE is an unusually large number of electrical Papers in Section G, the engineering coterie. After the conclusion of the presidential address, in which Prof. L. F. VERNON HARCOURT will call attention to the mutual relations of science and engineering, Major-Gen. WEBBER will open a discussion on "Light Railways in Agricultural Districts." Mr. PREECE, in conjunction with Mr. A. P. TROTTER, will describe a "New Portable Photometer." The chloride battery will be described by Mr. W. H. EARLE, and the Hermite sewage process by Mr. J. NAPIER, the borough analyst. We may mention that the Hermite process is in use at Ipswich. The subject of "Telephony" will be broached, in some of its recent aspects, by Mr. A. R. BENNETT, and the progress made in "Induction Telegraphy" will be reported by Mr. PREECE. Most of these electrical Papers in Section G will be brought forward on "electrical day," which this year falls upon Monday, the 16th.

IN our "Correspondence" columns this week will be found several additional contributions to the Magnetic Unit controversy. Dr. LODGE does not hold that the statement $\mathbf{N} = 10$ is sufficient; but, as Mr. W. B. SAYERS points out, "if only the C.G.S. system is taken for granted, nothing more is required than the number expressing the quantity of the thing in question." Dr. LODGE makes a good point when he urges that "those who hold that no simple multiples are of any use ought to speak of an event as going to occur in 15,834,000 seconds, instead of in three weeks. . . ." To this we venture to reply that no one does hold that simple multiples are in no case useful. The total flux in big dynamos measured in *lines* certainly runs into very big figures, but what of that? Dynamo designers, who alone experience the alleged awkwardness of these large totals, do not appear to feel any inconvenience. Moreover, *lines* hold the field, and "megalines," &c., do not. No doubt if every schoolboy had to handle *lines* in large quantities, the "megaline" would be needed; although even then frequent usage would, perhaps, soon accustom him to deal airily and easily in millions of lines. Dr. SUMPNER's wish that the names of units used by practical men should be allowed to evolve themselves, and his preference for names that are self-explanatory, is, we feel sure, largely shared by others. The drawback to this process, however, is that it tends to the evolution of different compound names in each country, and, in some degree, to the evolution of different units. The disadvantage would not, perhaps, be so formidable in fact as it is in imagination. Neither the French nor the German rendering of ampere-turn, secohm, or volt-line would be unrecognisable to Englishmen. The difficulty lies in securing the adoption of the same word-mixture in every country.

THERE is considerable ingenuity in the general principle of the methods by which Mr. ALBERT CAMPBELL proposes to obtain a constant potential difference, under varying temperature, at the terminals of a Clark standard cell; and the methods themselves appear to be quite practicable for commercial use, where this form of cell is employed during testing operations. If a Clark cell is circuited through a high resistance of any metal possessing a positive temperature coefficient, a rise in temperature will cause the resistance to increase while the electromotive force of the cell will diminish. As a result, the potential difference at the ends of the wire will tend to become constant. As Mr. CAMPBELL shows, by properly choosing the

Digitized by Google

material and magnitude of the resistance, and by arranging a number of these resistances in shunt and in series with the cell, the tendencies to change of the difference of potential between two given points may be set off against one another so as to cancel out completely.

THE net result, so far, of the indefatigable researches of Profs. DEWAR and FLEMING on the electrical behaviour of bismuth at low temperatures cannot be summed up more accurately than in their own words:—"These investigations indicate that the electrical behaviour of bismuth in certain states at and below particular temperatures is irregular, and that further study is necessary to arrive at a complete explanation of the facts." As, however, the further study stated to be necessary for the evolution of this much-to-be-desired complete explanation is—so the authors tell us in their Paper, which will be found elsewhere in the present issue—now actually in progress, and as revelations with regard to the conduct and character of electrolytic bismuth are promised shortly, we, in our turn, may hope that this decidedly inconclusive conclusion may prove but a temporary one.

THE general behaviour of bismuth is indeed indifferent, and when we come to its electrical resistance and thermo-electric power it is hopelessly vicious. The curves giving the specific resistance of this eccentric substance in relation to temperature all possess at least one bend, and some possess two. Had it been possible to lay the blame of the double bend upon impurities, something approximating to order might have been evolved out of chaos, and the physicist might have concentrated his explanatory powers upon the single-bend type of curve. Alas! 'twas not to be. A specimen of pure (?) bismuth prepared from the oxide by Mr. GEORGE MATTHEY yielded a single-bend curve, but then a specimen of pure (?) bismuth reduced from the oxychloride by Mr. EDWARD MATTHEY very inconsiderately gave a two-bend curve; whether by reason of its different origin or owing to the difference in the christian name of its preparer has not up to the present been definitely settled. An interesting discovery of Profs. DEWAR and FLEMING is that the sensitiveness of the electrical resistance of bismuth to a magnetic field is enormously increased at low temperatures; but as only one specimen was examined for this purpose, who can say whether this property is common to the substance called bismuth, or is merely peculiar to this particular specimen of it?

IT seems reasonable to anticipate that the so-called anomalous behaviour of bodies like bismuth will some day reward those who are now so patiently unravelling the tangle of observed facts, by revealing to them the meaning of the more decorous deportment of ordinary bodies. Eccentricity in the physical world is quite as trying to one's patience as it is when met with in the social world, and one can only hope it will perform as useful a function in the one as in the other.

THE British public is constantly being reminded, that as there are more things in heaven and earth than in orthodox philosophy, the chance that the inventor of a new (?) primary battery has been successful in bringing one of those things to light is not one to be laughed at. If every new name signifies a new thing, two of these inventors have got the latter in the "electric sand," with which it is proposed, firstly, to raise a capital of £50,000 in small-size shares, and afterwards to set about the "generation of electricity." But, the promises of "electric sand" are as nothing beside the promises of Mr. HYMEN LEVETUS. That gentleman has been proclaiming from the housetops the wonderful properties of the Milver Portable Electric Battery; and if one-half of these are to be relied upon, it is time for the horse and the dynamo builder to adjourn to the museum. The "Milver" battery does not, we are told, consume anything so expensive as zinc; it makes a daily 10-minutes meal on that wonderful material, "a substitute," and then it develops marvellous power for ten long hours. If you have a cathedral, Mr. HYMEN LEVETUS can give you a "Milver" battery that will light it; or if you merely want a glimmer to guide you to bed, it is not more difficult for the "Milver" to accomplish that than the lighting of St. Paul's. You need not live in England to enjoy these great benefits; for "arrangements have been made to secure the patent rights in fifteen countries." But, should it chance that you neither want to light your cathedral, nor in the small hours of the morning your staircase; nor yet to run a "produce wagon along the roads at the highest rate of speed"; there is still an advantage to be derived. For, if you put your money into this primary battery you will, so says that prophet, Mr. HYMEN LEVETUS, get back "twenty times the money invested."

The Theric-Oblasser Accumulator.—A company, with a capital of £30,000, has been formed in Germany to exploit the Theric-Oblatter patents in that country.

Cable Interruptions and Repair:—

	Date of Interruption.	Date of Repair.
Accra-Lagos	August 12th.	August 23rd.
Aden-Zanzibar	September 2nd.	—

Glasgow and West of Scotland Technical College.—The session for 1895-6 commences on Tuesday, October 1st. The entrance examination begins on Tuesday, the 24th inst. The Calendar for 1895-6 gives very complete particulars of the course of instruction in the day and evening classes.

Our Electrical Defences.—Operations have now been started for connecting Lavernock, the Flat Holm and Steep Holm, and Brean Down by an electric cable for the purposes of the Severn defence. The cable will be also connected with the Royal Engineers' offices in Canton and the Submarine Mining establishment at the docks, Cardiff.

Electric Motors and Cable Traction.—The cables on a three-mile section of the Chicago and City Railway Company are now being driven by means of a 700 H.P. Westinghouse continuous-current motor supplied with current from the mains. It is stated that the variations in load on this line are much more violent than would be the case with an electric tramway consuming about the same amount of power, the ammeter pointer rising and falling between 200 and 300 amperes within one-third of a minute.

Proposed Waterloo-City Overhead Railway.—It is rumoured that a project is on foot for the construction of an overhead railway from Waterloo Station to the City. All the necessary surveys have been made, and the Bill authorising the undertaking will be promoted in the next Session of Parliament by the South-Eastern Railway Company. The new line will compete with the underground electric railway now in process of completion connecting the South-Western Railway with the City at an almost identical point.

Digitized by Google

Electric Elevators.—The electric elevator is rapidly coming into general use in the United States. At first, says the *Western Electrician* of Chicago, central station managers were rather dubious of the effect upon their lighting circuits of the sudden and heavy demands for starting currents for the elevator motors; but they have found that this service forms a safe and desirable addition to their business. Probably 30 or 40 electric elevators have been installed in Chicago within the last year, and the business is also growing rapidly in the large eastern cities.

Expiry of a Secondary Battery Patent.—On Tuesday next will expire the secondary Patent No. 3926, granted September 10, 1881, to Mr. J. S. Sellon. The patentee expressly disclaims the use of spongy lead, &c., *per se*, and the use of corrugated or grooved plates "unperforated for the retention of such substances." His claim is: The use in the construction of secondary batteries of *perforated* plates or sheets, roughened, serrated, or indented, composed of lead, platinum, or carbon, upon, in, or against which plates, spongy or finely divided lead, or oxides or other salts, or compounds of lead or other suitable substances or compounds, are or may be held or retained substantially as and for the purposes hereinbefore described.

The Electric Conductivity of Heated Gases.—At a recent meeting of the Physical Society of Berlin, Dr. Pringsheim gave an account of his experiments on the electric conductivity of heated gases. In a Chamotte tube closed by brass caps the various gases, such as air, hydrogen, and carbon dioxide, were heated to a temperature of 700°C to 900°C. The electrodes consisted of circular discs of platinum capable of being placed at varying distances from each other. All the results obtained by Becquerel in 1853 were confirmed. As the electrodes were separated from each other the deflection of the galvanometer became less, and with constant distance between the electrodes the current became less the longer it flowed. This fact led to the suspicion, verified by experiment, that polarisation was here playing a part. On breaking the primary current, the polarisation of the electrodes was quite perceptible for fully a half-hour. The author concluded from the above that conduction in heated gases is an electrolytic phenomenon.

Obituary.—We regret to have to announce the death, on August 30th, of Mr. H. C. Hart, one of the first-class technical officers of the Engineer-in-chief's Office, Post Office Telegraphs. Mr. Hart joined the Telegraph Department in June, 1870, shortly after the transfer of the Company's business to the State. He has throughout his official career taken a keen interest in the great developments of the telegraph and telephone industries and in Post Office work generally. He was a Director of several of the mutual associations started and managed by Post Office men for the benefit of their brother officers. His loss will be deeply deplored by all with whom he was brought into contact. The interment took place on Monday, the 2nd inst., at Elmer's End Cemetery. Among those present to render a last tribute of respect to their late colleague were Mr. J. Hookey, assistant engineer-in-chief, Messrs. J. B. Chapman, T. H. Stockwell, P. Ennis, J. W. Curra, R. C. Leversedge, T. Reid and J. Ward of the Engineer-in-Chief's Office, and many representatives of other branches of the Post Office. The deceased was only 49 years of age.

Atmospheric Electricity.—The *Sitzungsberichte* of the Vienna Academy of Sciences (Vol. CIV.), says *Nature*, contains a discussion of the observations of atmospheric electricity and St. Elmo's Fire on the Sonnblick by Messrs. J. Elster and H. Geitel, being a continuation of the observations to the time of the change of the former observer. The results confirm those previously obtained, and show that the yearly variation of the electrical energy at the summit is small, compared to that at the base, and that the summit of the mountain projects above those strata of the atmosphere in which electrical processes mostly occur. During the fall of fine snow the St. Elmo's Fire is mostly negative, but positive when large flakes of snow and hail are falling. Dr. J. Hann has recently published a Paper on the conditions of atmospheric electricity on the summit of the Sonnblick. The discussion, says *Nature*, is one of much importance, and the subject is treated by Dr. Hann in a very thorough manner.

British Association, Section A.—The proceedings this year of the Mathematical and Physical Section of the British Association, so far as they are of electrical or allied interest, comprise the following Papers:—Prof. O. Henrici will read a Paper in this Section "On the Teaching of Geometrical Drawing in Schools," with a view to the appointment of a committee. Lord Kelvin and Messrs. M. Maclean and A. Galt will contribute a Paper "On the Electrification and Diselectrification of Gases;" Prof. A. W. Rücker will propose the question, "Do Vertical (Earth-Air) Electrical Currents exist in the United Kingdom?"; Messrs. Edier and Starling will discuss researches "On the Velocity of Light in a Rarefied Gas through which a Current is Passing"; Dr. G. J. Johnstone Stoney has a Paper "On the Events that go on within Molecules"; and Mr. W. H. Wheeler will report on Reduction of Magnetic Observations and on Electrical Standards. This Section will meet daily at 10·30 a.m., except on Saturday, when the proceedings will commence at 10 o'clock.

A Case of Globular Lightning.—In *The Times* of Tuesday Sir Charles S. King gives the following quotation from a memoir of the Rev. Dr. William Henry, F.R.S., a very close and careful observer, in which he describes an accident to Belturbet Castle, the then seat of Viscount Lanesborough, caused by globular lightning:—

> "About 20 years ago (1719), this castle was struck in an extraordinary manner with lightning, the traces of which are preserved to this day, and seem to confirm that philosophical opinion that what the vulgar call the thunderbolt is only the focus of that stream of liquid fire which is then discharged. This thunder struck the top of the castle close by the stack of chimneys, from which it shot down perpendicular to the bottom. The hole it made in the garret ceiling through which it darted is scarce 3in. diameter. This seems to be the very focus; from thence diffusing it knocked to pieces the stone of the hearth, and cut to itself a circular passage about 3ft. diameter; descending to the next floor, and growing more diffused, it cut through the hearth and floor a passage of about 8ft. diameter; from thence descending into the hall, and spreading wide, it, by the violent concussion of the air, dashed down two stands of arms hung round the hall, and broke out of the door, tearing down one side of it. Two women were in the hall—the one who stood on the further side, near the arms, was struck down, astonished but not hurt; the other, who was that instant shutting the door, was struck half dead; that side of her next the lightning was left all black, the other not in the least discoloured; she in a few days recovered, and attended me at the time I observed this progress of the thunder."

Water Power Station on the Sihl, near Zurich.—The water power station on the Sihl, near Zurich, of which some mention has been previously made in these columns, came into operation on the first of this month. The entire water of the river is retained by a dam, and the water is led along a canal about a mile and a-half long to a reservoir which has been excavated to a capacity of 48½ millions gallons. From the reservoir the water is led by an iron pipe, 4½ft. in diameter, to the turbines. A sluice valve is inserted at the opening of the pipe, by means of which the entire water can be kept back without the aid of sluice gates. The average rate of flow through the pipe is 350 gallons per second. Before the water begins to descend it flows a distance of some 70 yards, thence the pipe leads the water to the turbine house 160 yards off with a fall of 63 per cent. The pipe is made from rolled sheet, which is 0·2in. thick from the reservoir to the beginning of the drop, and thence 0·44in. thick. At the turbine house there are at present three 500 H.P. turbines, to which later on two more will be added. The plant is designed to generate a total of 1,800 H.P., of which 1,000 H.P. will be devoted to lighting and the rest to power purposes. At the present moment agreements to take power for several years are in view, a total of 500 H.P. being required. As soon as the station commences work, some 4,400 8 c.p. lamps will require current, and 1,000 more are expected to be connected up shortly. The engineer of the station is Herr Wissling, previously head of the municipal electrical plant at Zurich.

Wiring Rules of the Paris Municipality.—The Paris Municipal Council has recently published a set of wiring rules, which will apply not only to installations connected to the municipal mains, but also to those connected to the mains of the various electric lighting companies of Paris. Rule 2 lays down that the copper conductors shall have a resistance of not more than 1·8 microhms per cubic centimetre at 20°C.—that is to say, they are to be of about 97 per cent. conductivity. Rule 3 lays

Digitized by Google

down that the cross-section of the conductors is to be such that in the event of the accidental passage of a current of twice the normal amount, it shall not heat up more than 40°C. The maximum permitted current densities are as follows: 1,935 amperes per square inch for wires between Nos. 18 and 13 B.W.G., 1,290 amperes per square inch for wires between Nos. 13 and 1 B.W.G., and 645 amperes per square inch for larger conductors. The permissible density is double this when bare conductors are used. No single wire conductor of less than No. 20 B.W.G. is permitted. Rule 5 states that fuses must melt for currents equal to not more than three times the normal amount. Rule 7 states that a special tablet is to be placed upon houses which are electrically lit. By Rule 12 casing is permitted. With regard to arc lamps it is stated that the wires of the rheostats in connection with them are to be so arranged as not to attain a higher temperature than 200°C, and the resistance wires of the rheostat are to be separated from the base of the apparatus by at least 2in. of air. By Rule 15 all fixtures serving both for gas or electricity are to be mounted on insulated bases, having a resistance of at least half a megohm. Rule 16 reads as follows: "Every conductor which can be separated from the general network by the movement of a switch or the taking out of a fuse shall have an insulation resistance either with regard to earth or to its neighbouring conductor, which, expressed in ohms, shall not be lower than 5,000 E/2, E being the potential difference in volts measured at the terminals of the generator or transformer. In insulation tests the difference of potential employed shall be equal to E, not, however, exceeding 500 volts, nor going below 100."

The Telephotograph.—The telephotograph is the name of a new Swedish invention, which, according to *Engineering*, claims to do for the eye something like what the telephone does for the ear. It is based upon the peculiarity of selenium, that its resistance to the transmission of electricity depends to a great extent upon the strength of the light to which it is exposed. The construction of the telephotograph is simple enough, but it is not so evident that it would work as described. A fine point of selenium is made to move in a plane by a mechanical arrangement in such a manner that, moving repeatedly forward and backwards, within a limited compass of this plane, it describes a spiral consisting of very close windings. An electric current passes through the selenium point, and the power of this current will vary according to the light to which the point at any given moment is exposed. The receiver is constructed in a similar manner to the above, except that a very susceptible incandescent light has been substituted for the selenium point. The intensity of this light will, it is said, vary in harmony with the light to which the selenium point is exposed, though we should have thought there would be a perceptible lag and damping effect, considering the speed with which the lamp must be moved in its cycle. When the light is made to move in a similar manner to the movements of the selenium point, it will produce lights and shadows on the plane. The despatching apparatus is inclosed in a case, something like a photographic camera, fitted with an objective, which can be so adjusted that the picture of the subject to be telephotographed is formed in the movement plane of the selenium point. The lights and shadows produced by the incandescent light of the receiving apparatus will then, so it is said, produce a picture identical with the one at the despatching station. The rapidity of the movements of the selenium point through any one point of the picture must not allow of a greater interval than about one-eighth of a second, so that the corresponding impressions upon the eye of the beholder form a continuous complete picture.

African Telegraph Rates.—In the House of Commons on Wednesday Mr. Hanbury moved that the agreements (1) dated July 9, 1895, between the Treasury, the Colonial Governments of the Cape of Good Hope and Natal, and the British South Africa Company respectively, and the Eastern and South African Telegraph Company; (2) dated July 10, 1895, between the Treasury and the same Telegraph Company, providing for a reduction in the charges for telegrams between South Africa, certain places on the East Coast of Africa, Mauritius, and Seychelles on the one hand, and Europe on the other, be approved. Agreed to.—— The agreements referred to above are embodied in a Parliamentary Paper just published. The agreements provide for a reduction, now in force, in the charges for telegrams between South Africa, certain places on the East Coast of Africa, Mauritius and Seychelles on the one hand, and Europe. The rates per word previously varied from 7s. 6d. to 8s. 11d. for ordinary telegrams, and from 5s. 9d. to 6s. 4d. in the case of Government telegrams, and the Telegraph Company has undertaken to reduce the rates in the case of South African traffic by both the East and West Coast routes to rates which are approximately 5s. a word for ordinary and 2s. 6d. a word for Government telegrams. The Home Government and the contracting colonies have undertaken, by the first agreement, to grant, as from December, 1899, a subsidy of £17,000 per annum for 10 years, in the following proportions: By Her Majesty's Treasury, £8,750 per annum; by the Government of the Cape Colony, £6,000 (in the event of the Orange Free State paying to the Telegraph Company the sum of £200 per annum, this sum to be reduced to £5,800); by the Government of Natal £1,650, and by the British South Africa Company £600. Provision is made for a rebate in the subsidy if, during the last five years of the period of 10 years mentioned, the net receipts of the Telegraph Company exceed £180,000 in any one year. Under a second agreement the Home Government undertake to grant to the Telegraph Company an annual subsidy of £3,500, payable for 10 years as from January 1, 1900.

The Institution of Civil Engineers.—Subjects for Papers.—The Council of the Institution of Civil Engineers invites original communications on the subjects included in the following list, as well as on any other questions of professional interest. This list is to be taken merely as suggestive, and not in any sense as exhaustive. For approved Papers the Council has the power to award premiums, arising out of special funds bequeathed for the purpose. The following is a list of the subjects of electrical engineering interest suggested: The Purification of Sewage by Precipitation, Filtration, Electrolytic, Bacteriological and Chemical Processes—The Use of Ash-bin Refuse in Towns for the Production of Steam—The Methods of Condensing Steam by the Use of Moderate Quantities of Water—The Methods of Removing Moisture from Steam, and of Reducing Losses by Radiation from Steam Pipes—The Production and Use of Super-heated Steam—The Theory and Development of the Compound Steam Turbine—The Recent Developments in Gas Engines and Oil Engines, including a comparison of the relative merits of the several Cycles, with reference to "after-burning"—The Design and Construction of Large Turbines—The Magnetic Properties of Iron and Steel—The Extraction of Metals from their Ores by Electrolytic Processes—The most suitable Steam-power Equipments for Electric Light Stations—The Utilisation of Electric Lighting Plant during hours of small demand—The Utilisation of Electrical Energy in the form of Heat—The Regulation of Electric Pressure in large lighting circuits as carried out at the engine, the dynamo or the exciter—The Theory and Practice of the Transmission of Power by Alternating Currents—The Use of Electrical Motors for Driving Machines in textile factories and in engineering workshops—The first cost, facility and economy of operation of Electrical Traction on Railways with heavy trains and on Tramways—The Construction and Working of Electrical Lifts and Cranes—The Electrolytic Action of Return Currents in Electrical Tramways on Gas and Water Mains, and the best means of providing against Electrical Disturbances—The Use of Electrical Machinery for Lighting and the Transmission of Power in Warships and in the Mercantile Marine. In writing these essays the use of the first person should be avoided. They should be legibly transcribed on foolscap paper, on one side only, leaving a margin on the left side, in order that the sheets may be bound. Every Paper must be prefaced by an abstract of its contents not exceeding 1,500 words in length. Illustrations, when necessary, should be drawn on tracing paper, to as small a scale as is consistent with distinctness, but in no case should any figure exceed 6½in. in height. When an illustrated communication is accepted for reading, a series of diagrams will be required so drawn and coloured as to be clearly visible at a distance of 60ft. These diagrams will be returned.

ON SELF-ACTING COMPENSATION FOR TEMPERATURE IN STANDARD CELLS.

BY ALBERT CAMPBELL.

In accurate testing work, when a standard cell is used, in most cases it is necessary to observe the exact temperature of the cell and to make a correction for it. In the case of the Clark cell the temperature coefficient is commonly given $= -0{\cdot}077$ per cent. per degree C. Dr. Kahle (*Wied. Ann.*, p. 174, No. 1, 1894) gives it a little higher, viz. $= -0{\cdot}083$ per cent. per degree C. Carhart's one-volt standard cell, in which calomel paste and solution of zinc chloride replace the corresponding sulphates, is stated to have a coefficient as small as $+0{\cdot}0097$ per cent. per degree C., and Weston's cadmium cell seems almost as invariable. But whatever be the merits of the two last-named cells, the Clark cell is at present the most widely received standard, and therefore any simple arrangement which gets rid of the correction for temperature must be of distinct advantage. Below are three methods which I propose for this purpose; as far as I know, they are novel.

The principle used in all of these is to make the variations in resistance of metallic conductors counterbalance the changes of E.M.F. in the standard cell. Since the amount of compensation *required* is approximately proportional to the variation of temperature, it is only necessary (*a*) to make the *applied* compensation also proportional to that variation, and (*b*) to ensure that the compensation acts correctly for a temperature rise of 1 degree.

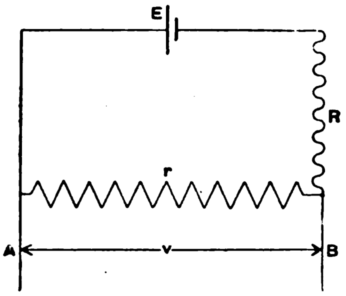

FIG. 1.— ⁀⁀⁀ = Manganin. /\/\/\/\ = Copper or Nickel.

Method 1.—In this the standard cell is placed in series with two high resistances of materials having different resistance temperature coefficients. As will be shown below, by properly choosing the materials and the magnitudes of these resistances the potential difference on one of these resistances can be rendered nearly independent of temperature.

In Fig. 1 let E be the E.M.F. of the standard cell and R, r the resistances in series with it, all being at the normal temperature.

Also let η, a, and β be the temperature coefficients of E, r, and R respectively. Let the potential difference between A and $B = v_0$ at the normal temperature and v_1 when the temperature rises 1°C. Take r and R so high that the resistance of the cell may be neglected.

Then $$v_0 = \frac{r\mathrm{E}}{r+\mathrm{R}}$$

and $$v_1 = \frac{\mathrm{E}(1+\eta)}{1+\frac{\mathrm{R}}{r}\left(\frac{1+\beta}{1+a}\right)} = \frac{\mathrm{E}(1+\eta)}{1+\frac{\mathrm{R}}{r}(1+\beta-a)}$$

$$= \frac{\mathrm{E}(1+\eta)}{\frac{r+\mathrm{R}}{r}\left[1+\frac{\mathrm{R}}{r+\mathrm{R}}(\beta-a)\right]}$$

$$= \frac{r\mathrm{E}}{r+\mathrm{R}}\left[1+\eta-\frac{\mathrm{R}}{r+\mathrm{R}}(\beta-a)\right].$$

Now, if v is to be constant, $v_1 = v_0$, and we must have

$$\eta = \frac{\mathrm{R}}{r+\mathrm{R}}(\beta-a).$$

This condition is easily satisfied if

r be of copper and $\therefore a = 0{\cdot}0040$,
R of German silver and $\beta = 0{\cdot}0004$,
E a Clark cell and $\eta = -0{\cdot}0008$.

So $$\frac{\mathrm{R}}{r+\mathrm{R}} = \frac{0{\cdot}08}{0{\cdot}36} = \frac{2}{9};$$

hence $$\frac{r}{\mathrm{R}} = \frac{7}{2}.$$

We can therefore make $r = 70{,}000$ ohms and $\mathrm{R} = 20{,}000$ ohms, in which case we shall have a constant voltage of about 1·115 volts from B to A.

Instead of making the coil r of copper, which is not a suitable material for high resistances, *nickel* might be used. According to Dewar and Fleming, pure nickel has a resistance temperature coefficient of 0·0062 per degree C.; according to my own experiments (*Proc. Roy. Soc., Edin.*, July, 1887) the coefficient for ordinary commercial nickel is sometimes as low as 0·0040. In any case, if annealed nickel be found to undergo no sensible change as it ages (a point which is yet doubtful), it would, from its higher resistivity, be preferable to copper in all the arrangements here described.

To the above method, however, there is the serious objection that, unless very high resistances are employed, the internal resistance of the cell will not be negligible, and, besides, the cell will polarise. The other two methods which I now proceed to describe are quite free from these defects.

Method 2.—The second way might be called the *auxiliary cell method*, for in it the small variations in E.M.F. of the standard cell are compensated by adding or subtracting a small fraction of the E.M.F. of an auxiliary cell, the magnitude of this added part being automatically regulated by the temperature.

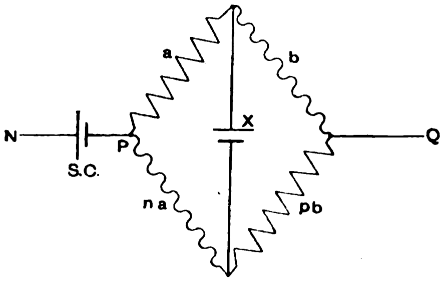

FIG. 2.—S.C. = Standard Cell. X = Auxiliary Cell.
/\/\/\/\ = Copper or Nickel. ⁀⁀⁀ = Manganin.

The arrangement will be seen from Fig. 2, in which the auxiliary cell (X) is shown connected up as in a Wheatstone's bridge, the resistances a and $p\,b$ varying with temperature, while the other arms $n\,a$ and b are practically constant. The auxiliary cell may be a Daniell, Leclanché, or other battery, whose E.M.F. is known to within about 5 per cent., and which will keep fairly constant when run on high resistance.

It is clear from the figure that, if the bridge resistances balance, the voltage from P to Q will = 0, and therefore the voltage from N to Q will be only the E.M.F. of the standard cell. If, however, the bridge, by change of temperature or otherwise, is not in balance, the voltage from N to Q will = E.M.F. of standard ± some fraction of E.M.F. of auxiliary. Let us now investigate if a, b, n, and p can be chosen so as to keep the voltage from N to P constant while temperature varies.

Let a and 0 be the temperature coefficients of a and b respectively, and let η, as before, equal that of the standard cell. To simplify matters, let the cell X be the only resistance in the cross circuit, and let its resistance be small compared with $a + n\,a$ and $b + p\,b$.

Let X = E.M.F. of the auxiliary cell;

V_0 and V_1 = potential rise from P to Q at the normal temperature and at 1°C. above it, respectively.

Then $$\mathrm{V}_0 = \mathrm{X}\left[\frac{p}{1+p} - \frac{n}{1+n}\right]; \quad \ldots \ldots \quad (1)$$

$$\mathrm{V}_1 = \mathrm{X}\left[\frac{p(1+a)}{1+p(1+a)} - \frac{n}{1+a+n}\right];$$

$$\therefore \mathrm{V}_1 - \mathrm{V}_0 = \mathrm{X}\left[\frac{ap}{(1+p)(1+p+ap)} + \frac{an}{(1+n)(1+a+n)}\right]$$

$$= \mathrm{X}a\left[\frac{p}{(1+p)^2} + \frac{n}{(1+n)^2}\right]$$

if neither p nor n is much greater than unity.

Digitized by Google

$$\therefore V_1 = X\left[\frac{p}{1+p} - \frac{n}{1+n}\right] + X\,a\left[\frac{p}{(1+p)^2} + \frac{n}{(1+n)^2}\right]. \quad . \quad (2)$$

This equation will now enable us to choose suitable values for p and n. If the values of X and a be fixed, the maximum possible variation of V is when $\frac{p}{(1+p)^2} + \frac{n}{(1+n)^2}$ is a maximum. Now, since both p and n must be positive, each term in this expression must be a maximum, and it is easy to show that the condition for this is $p = n = 1$. Thus the maximum variation $= X\frac{a}{2}$.

If $X = 1{\cdot}5$ volts and $a = 0{\cdot}0040$, the variation in the auxiliary volts cannot exceed 0·003 volt per degree C. Accordingly a single Leclanché cell at X is more than sufficient if the standard is a Clark cell, for in it the variation to be compensated is only 0·0011 volt per degree C. Let us now find what values of p and n will give good compensation. Putting in the above values of X and a, equation (2) becomes

$$V_1 = 1{\cdot}5\left[\frac{p}{1+p} - \frac{n}{1+n}\right] + 0{\cdot}006\left[\frac{p}{(1+p)^2} + \frac{n}{(1+n)^2}\right]. (3)$$

Case I.—Let $p = n$. In this case the auxiliary volts (V) vanish at the normal temperature.

Equation (3) becomes

$$V_1 = \frac{0{\cdot}012\,n}{(1+n)^2}.$$

Now $V_1 = 0{\cdot}0011$ volt for correct compensation; hence $p = n = \frac{49 \pm 47{\cdot}75}{11} = 8{\cdot}795$ or $0{\cdot}123$. With either of these values the volts from N to Q (Fig. 2) for all ordinary temperatures will keep steadily equal to the E.M.F. of the standard cell at the temperature at which the bridge arms are adjusted to balance. The final adjustment can be made by connecting a sensitive galvanometer to P and Q and adjusting one arm of the bridge until a balance is obtained.

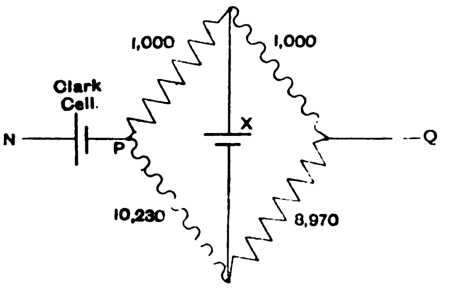

FIG. 3.—[zigzag line] = Copper or Nickel. [wavy line] = Manganin.

Case II.—Let p be not equal to n. When this is the case the first part of V_1 in equation (3) does not vanish, and this gives, in addition to the second term, which forms the temperature compensation, a small constant voltage to be added or subtracted. We can, therefore, choose n and p, so as to have correct compensation, and at the same time to bring the total voltage to an even figure, say 1·400, at all temperatures.

To investigate the general case, let

$$\frac{p}{1+p} - \frac{n}{1+n} = k \quad . \quad . \quad . \quad . \quad . \quad (4)$$

and

$$\frac{p}{(1+p)^2} + \frac{n}{(1+n)^2} = m. \quad . \quad . \quad . \quad . \quad (5)$$

From (4)

$$p = \frac{n(1-k) - k}{nk + k + 1} \quad . \quad . \quad . \quad . \quad (6)$$

Substituting this in (5), and reducing, we have

$$(k + k^2 + m)\,n^2 - 2\,(1 - k^2 - m)\,n - k + k^2 - m = 0. \quad . \quad (7)$$

Equations (7) and (6) give the values of p and n for any desired values of k and m.

For example, let us aim at $V = 1{\cdot}400$ volts.

Here $$k = \frac{1{\cdot}400 - 1{\cdot}434}{1{\cdot}5} = -0{\cdot}02265,$$

and $$m = \frac{0{\cdot}0011}{0{\cdot}0060} = 0{\cdot}1833.$$

Hence $n \doteqdot 10{\cdot}23$, and $p \doteqdot 8{\cdot}97$.

Thus, if the resistances in Fig. 3 are right at 15°C, and $X = 1{\cdot}5$ volts, the voltage from N to Q will be 1·400 volts at all temperatures near 15°C.

In practice it would be safer (after the coils have been arranged approximately, as in Fig. 3) to observe the temperature of the whole, and then, by means of a potentiometer, comparing V_{NQ} with the E.M.F. of the Clark cell alone, to adjust one of the arms slightly, so as to bring V_{NQ} to 1·400 volt. This final adjustment would not sensibly interfere with the temperature compensation. Introducing resistance in branch X would afford another means of adjustment. For cells (like Carhart's) in which the E.M.F. increases with temperature, the auxiliary cell would merely have to be reversed.

Method 3.—To make this method clear let us consider Fig. 4.

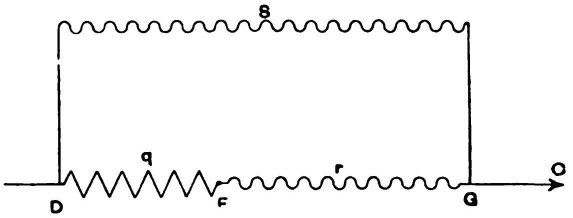

FIG. 4.—[zigzag line] = Copper or Nickel. [wavy line] = Manganin.

A current C from an outside source flows from D to G through the resistances q, r, and s, arranged as in the figure. Let q be more variable with temperature than r and s. Now it is possible to choose the values of q, r and s so that *C can remain absolutely invariable* and yet produce from F to G a potential difference exactly equal to the E.M.F. of a Clark cell *and having the same temperature variation.*

Let C be constant and let U_0 and U_1 = potential differences from F to G at the normal temperature and at 1°C. above it, respectively; also let a be the temperature coefficient of q, β that of r and s, and η that of the Clark cell.

Then $$U_0 = \frac{r}{q+r} \times \frac{(q+r)\,s}{q+r+s}\,C = \frac{C\,r\,s}{q+r+s};$$

$$\therefore \quad U_1 = C\frac{r\,s\,(1+\beta)^2}{q + q\,a + r + r\beta + s + s\beta}$$

$$\doteqdot C\frac{r\,s}{q+r+s}(1 + 2\,\beta)\left(1 + \frac{q\,a + r\,\beta + s\,\beta}{q+r+s}\right)$$

$$\doteqdot \frac{C\,r\,s}{q+r+s}\left[1 + \frac{(2\,q + r + s)\,\beta - q\,a}{q+r+s}\right].$$

Since U is to have the same variation as the Clark cell we must have

$$\eta = \frac{(2\,q + r + s)\,\beta - q\,a}{q+r+s}. \quad . \quad . \quad . \quad . \quad . \quad (8)$$

The simplest solution is to make r and s of manganin, so that $\beta = 0$, and the equation becomes

$$\frac{a}{\eta} = -\frac{q+r+s}{q} = -1 - \frac{r+s}{q}. \quad . \quad . \quad . \quad (9)$$

If q be of copper, $\frac{a}{\eta} = 5$;

$\therefore$ (9) becomes $r + s = 4q$. . . . . (10)

This is the required condition.

The method is best employed along with a potentiometer, as shown in Fig. 5. Here G H K are the potentiometer wires. The absolute values of q, r, and s are to be chosen to fulfil the condition in equation (10), and so that when the potential difference between F and G is just balanced by the Clark cell, the current through G H K will be just the right strength to make the potentiometer read directly in volts. The final adjustment can be made once for all as follows:—Observe the temperature and let the corresponding E.M.F. of the Clark cell $= E_t$. Adjust the current until the Clark cell balances when in position L′ with a potentiometer reading $= E_t$. Then slightly alter the position of the junction at F until the cell balances when shifted to position L. After this the Clark cell

Digitized by Google

is kept permanently in position L. To use the potentiometer now it is only necessary to adjust the current until the Clark cell balances (at F and G). The potentiometer will then read directly in volts and be independent of temperature to the third place of decimals.

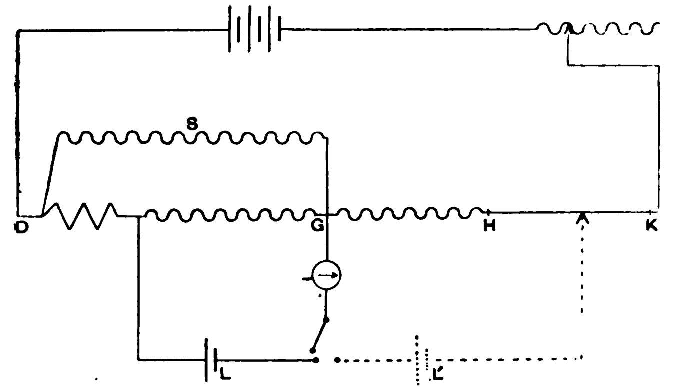

FIG. 5.— ∿∿∿∿ = Manganin. ∧∧∧∧∧∧ = Copper or Nickel.

In conclusion, two practical points should be noted: firstly, that the standard cell should be in the same case, if possible, as the compensating coils to ensure all being at the same temperature; and, secondly, that the copper or nickel resistances must be of such mass as not to be appreciably heated by the currents used.

THE MAGNETIC FIELD OF A RECTANGULAR CURRENT.

BY PROF. G. M. MINCHIN, M.A., F.R.S.

In the following Paper is given the expression for the magnetic force per unit pole at any point in the plane of a given rectangle when this rectangle is traversed by an electric current.

Let A B C D (Fig. 1) be a wire bent into the form of a rectangle and traversed by a current of strength i, and let P be any point whatever in space. From P let fall P Q perpendicular to the plane of the current; through Q draw L Q N and

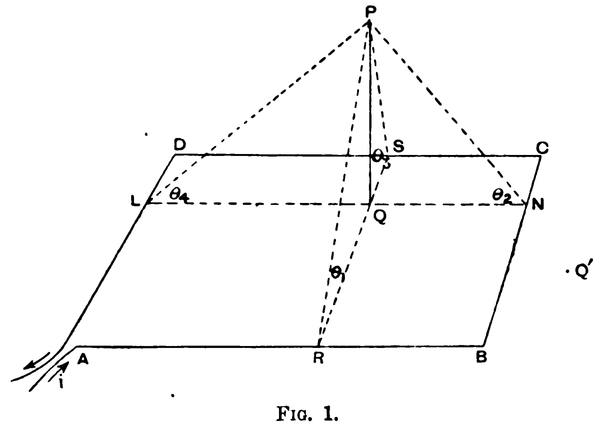

FIG. 1.

R Q S parallel to the sides of the rectangle. Now, if Ω is the conical angle subtended at P by the rectangular contour, we know that the magnetic potential at P due to the current i is $i\Omega$. This conical (usually called "solid") angle is thus defined: Round P as centre describe a sphere of any radius, r, and from P draw lines to all points on the contour A B C D; then these lines will cut the surface of the sphere in a spherical quadrilateral, the area of which, divided by r^2, is the conical angle. We have, then, to consider the quadrilateral in which the sphere is intersected by the four planes P A B, P B C, P C D, P D A.

Now, if the internal angles of *any* polygon formed by great circles of a sphere are (in circular measure) $A_1, A_2, A_3, \ldots$, the area of the polygon is

$$\{A_1 + A_2 + A_3 + \ldots - (n-2)\pi\} r^2, \quad . \quad . \quad (1)$$

n being the number of sides of the polygon; so that in the present case the conical angle subtended at P by A B C D is

$$A_1 + A_2 + A_3 + A_4 - 2\pi. \quad . \quad . \quad . \quad . \quad (2)$$

[Every polygon, or closed curve, on a sphere must, of course, be considered as having *two* areas, according to the portion of the spherical surface which we consider as *inside* or *outside* the contour of the curve. In this case it is the portion of the sphere which faces the circuit A B C D that we consider to be the area.]

The angles, $A_1, A_2, \ldots$, of the spherical quadrilateral are, of course, those between the planes P A B, P B C, . . . ; and it is easily proved either by spherical trigonometry or by analytical geometry that if the angles P R S, P N L, P S R, P L N are denoted by $\theta_1, \theta_2, \theta_3, \theta_4$, the angle between the planes P A B, P B C is $\pi - \cos^{-1}(\cos\theta_1 \cos\theta_2)$, with similar expressions for the angles between the other planes.

Hence, then, we have

$$\Omega + 2\pi = A_1 + A_2 + A_3 + A_4$$
$$= 4\pi - \cos^{-1}(\cos\theta_1 \cos\theta_2) - \cos^{-1}(\cos\theta_2 \cos\theta_3) \ldots; \quad (3)$$

so that if $\cos\theta_1, \cos\theta_2, \ldots$ are denoted by $c_1, c_2, \ldots$, we have finally

$$\Omega = 2\pi - \cos^{-1}(c_1 c_2) - \cos^{-1}(c_2 c_3) - \cos^{-1}(c_3 c_4) - \cos^{-1}(c_4 c_1). \; (4)$$

The most simple way to find the value of the magnetic force at any point, Q, in the plane of the rectangle is to take P indefinitely close to Q in Fig. 1, and to take the difference between the value of Ω for Q and the value of Ω for P, and divide this difference by the length P Q; for the force at P in any direction is the differential coefficient of Ω in that direction, multiplied by i.

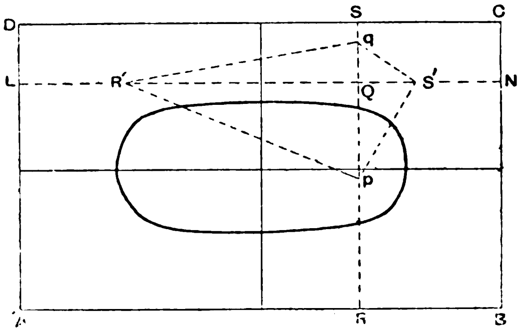

FIG. 2.

Now Ω at Q and at all points in the plane of A B C D *within* the contour is 2π, as is well known, while Ω at all points in the plane and *outside* the contour is 0. Suppose P very close to Q; let $PQ = z$, $RQ = l$, $QN = m$; then $\cos\theta_1 = 1 - \frac{z^2}{2l^2}$, nearly, and $\cos\theta_1 \cos\theta_2 = 1 - \frac{z^2}{2}\frac{l^2 + m^2}{l^2 m^2} = 1 - \frac{z^2}{2}\frac{RN^2}{l^2 m^2}$; so that the circular measure of the angle whose cosine is $\cos\theta_1 \cos\theta_2$ is $\frac{z \, . \, RN}{lm}$, or $\frac{z}{p_1}$, where p_1 is the perpendicular from Q (or from B) on R N.

Hence, then, if p_1, p_2, p_3, p_4 are the lengths of the perpendiculars from Q on the lines R N, N S, S L, L R, the value of Ω at P is

$$2\pi - z\left(\frac{1}{p_1} + \frac{1}{p_2} + \frac{1}{p_3} + \frac{1}{p_4}\right),$$

and hence the value of the magnetic force intensity at Q is

$$i\left(\frac{1}{p_1} + \frac{1}{p_2} + \frac{1}{p_3} + \frac{1}{p_4}\right), \quad . \quad . \quad . \quad . \quad (5)$$

which is a simple result, published now for the first time, so far as I am aware. Of course for a point, such as Q', in the plane of the rectangle, but outside its area, a similar result holds with the proviso that two of the perpendiculars (p_1, p_2) become negative. We must observe also that such a result as (5) obviously supposes that the point Q is not near any side of the rectangle—or, at least, is so distant that the diameter of the cross-section of the wire may be neglected and the wire still considered to be a mere *line*.

Digitized by Google

There is a practical way of using the result (5) which will assist graphic construction. In practice it is difficult, or troublesome, to measure reciprocals, $\frac{1}{p_1}$, &c., so that we must endeavour to get an expression depending on the measurement of *direct* lengths. This can be done as follows :—

Let Q, Fig. 2, be the point at which the magnetic force is required ; draw L Q N, R Q S, parallel to the sides ; on Q N) take S′ such that Q S′ = Q S, and R′ such that Q R′ = Q R ; from S′ draw S′ q and S′ p parallel, respectively, to L R and R N ; draw R′ q, R′ p. [Of course, it is easy to see that R′ q, R′ p are parallel to L S, S N.] Then (5) is equivalent to

$$i \cdot \frac{\text{length of contour } p\,S'\,q\,R'}{Q\,R\,.\,Q\,S}, \quad . \quad . \quad . \quad (6)$$

in which, then, the only reciprocal that has to be taken is that of the product Q R . Q S ; but this is always easily at our disposal if the drawing is made on section-paper. There is no difficulty in verifying the equivalence of (5) and (6), so that it is not worth while to occupy space with the proof.

The oval curve contains on its contour all points at which the magnetic force has a certain constant value, chosen arbitrarily, and it was constructed with considerable ease and rapidity by the rule contained in (6). It may be observed that there is a tendency to corners, or abrupt change of curvature, in such curves.

The case in which the point Q, at which the value of the force is required, lies very close to some part of the current remains for investigation.

NOTES ON SOME EXPERIMENTS WITH ELECTRO-MAGNETIC MECHANISM.

BY P. V. McMAHON.

(Concluded from page 587.)

The last and not least important set of observations are plotted on Fig. 29, and are the results of experiments with the 14in. double-taper core, with the second spring, the different curves being obtained by altering the initial tension of the spring and also the position of the point of the core with respect to the outside edge of the coil at starting. The variation of excitation was maintained the same, viz., 280 ampere-turns for all the curves, *i.e.*, *a* to *f*. Starting with *a* the travel for the above-named variation is only 1·4in. Here, before the current was switched on, the point of the core was 3·25in. outside the coil, and the spring had no initial tension. The first reading (or the first point of balance between ampere-turns and spring) was obtained when the core point was 7·4in. outside the coil. It is thus evident that the core passed rapidly over the first part of the scale. These first points on the curve were not observed, as the object of this experiment was to find the difference between the curves when the core started under different conditions for the same ampere-turns at start and finish. Consequently, the first and last points on the curve must correspond with those of curve *f*. This first curve *a*, in addition to having the shortest travel, is also the worst curve, being nearly part of a semicircle.

The second curve, *b*, was obtained under the following conditions : The point of the core was flush with the outside edge of the coil before the current was switched on, or 3·25in. of core less through the coil than in *a*. For the minimum excitation (580 ampere-turns) the point of the core settled down 5·5in. outside the coil, the travel in this case being 2·45in. The shape of the curve is much better than *a*, although it bends over a little towards the end of the travel.

The spring was arranged as in *a*—*i.e.*, it had no initial tension at the start.

In the third curve, *c*, the point of the core was 3·25in. outside the coil, as in *a*, but here the spring had an initial tension corresponding to a torque of 0·99 inch-ounces. With minimum excitation the core point stood 5·05in. outside the coil, or 0·45in. less than in *b* ; the travel in this case was 2·8in. The curve is somewhat similar in shape to those obtained with the two 8in. cores, only the deviation from a straight line is not so marked.

Coming to the fourth curve, *d*, the point of the core was flush with the outside of the coil, as in *b*, but the spring had an initial tension corresponding to a torque of 0·99 inch-ounces ; with minimum excitation the core point took up a position 2·6in. outside the coil, and the travel was 4·35in. The curve, as will be apparent on inspection, is a perfectly straight line.

The next curve, marked *e*, was arranged under similar conditions to *d*, with the exception that the spring was given an initial tension corresponding to 1·21 inch-ounces torque ; with minimum excitation the point of the core stood 1·35in. outside the coil, and the travel is just the same as in *d*, viz., 4·35in. This curve is not quite straight, but bends slightly at the beginning.

The sixth and last curve, *f*, was arranged so that the core point was flush with the edge of the coil, without the current flowing, and with the minimum excitation the core remained in

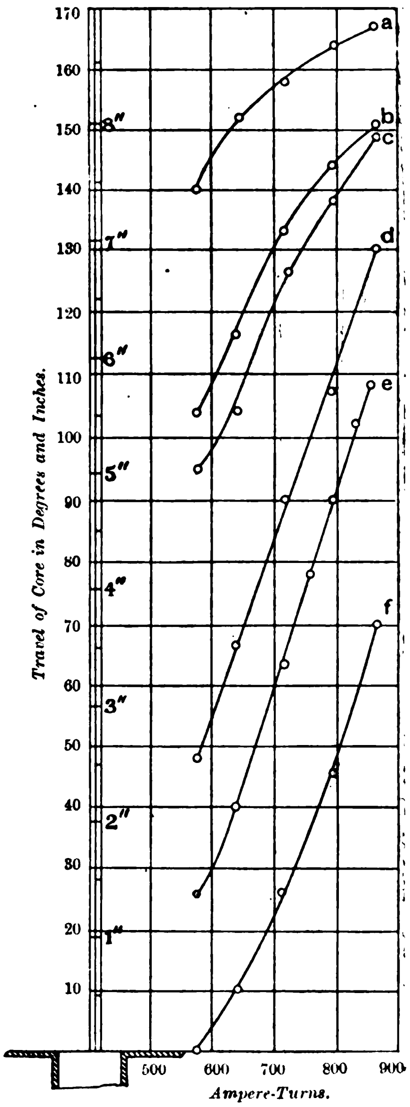

FIG. 29.

the same position. The spring had an initial tension corresponding to a torque of 1·32 inch-ounces. The travel was 3·7in., and the curve not so good as *d* or *e*.

The set of curves given above clearly show how it is possible to vary not only the shape of the curve, but also its travel, by adjusting the spring and the position of the coil with respect to the core.

Here we start under conditions giving a short travel and a bad curve, and gradually come to a maximum travel and a perfectly straight line ; altering the condition still further by increasing the resistance to the movement of the core, the travel becomes small, and the curve deviates again from a straight line. Another noteworthy point about these curves is that each curve becomes straighter until a perfectly straight

Digitized by Google

line is reached; then the curves gradually bend in the reverse direction.

Owing to the initial tension of the spring being altered several times it is not possible to give a scale for the torque exerted. However, it can be found by multiplying the travel in degrees by 0·011 (the torque in inch-ounces per degree as found from calibration of the spring) and adding the value of the torque in inch-ounces corresponding to the initial tension, thus:—

—	Travel in degrees.	Torque in inch-ounces.
a..................	140—167	1·54—1·83

The latter experiments with cores and solenoids may be said to be successful as regards sensitiveness, range and shape of curve, but weak as regards the turning moment. It appeared as if this weakness was due to the fact that the return path for the lines of force was through air and not iron.

To try the effect of a closed magnetic circuit, several experiments were made with an electro-magnet, resembling the field-magnet of a dynamo in appearance, and various shaped armatures. In all cases with an iron return in the magnetic circuit the mechanism was very sluggish; most of the armatures tried gave no movement at all for a considerable variation of the excitation, but in all cases the mechanism was infinitely stronger than when no iron return was provided.

It would seem as though this sluggishness was due to the fact that the air gap used was in all cases very short, and on the whole the magnetic circuit was short and of large cross-section, thus resembling a closed magnetic circuit, and consequently the variation in the lines did not follow the variation or excitation in anything like the same relation as in the earlier experiments with solenoids and core.

The truth of this statement is borne out by the experiments that followed, in which large pole-pieces were used, and the return magnetic circuit through air. Here the mechanism was not so strong for the same weight of material (copper and iron) and expenditure of energy as with the preceding arrangement, but it was stronger than the solenoid and even more sensitive.

The results and curves (where obtainable) with the closed magnetic circuit are given, not on account of their success, but rather on account of their failure, to comply with the required conditions set forth in the commencement. Although not satisfactory from this point of view, the experiment with the shuttle-wound armature and large pole-pieces forms an excellent piece of mechanism, where on switching on the current a very large movement or range and a strong pull or turning movement is required, as in the case of automatic signals, &c., for railway working.

Fig. 30 is a half-size drawing of field-magnets used in all experiments with a return magnetic circuit. The limbs and yoke are built of charcoal iron plates like transformer stampings No. 20 B.W.G., with a thin layer of varnished paper between each plate. The different pole-pieces were held in position by brass clips and wooden wedges, and the joints between the pole-

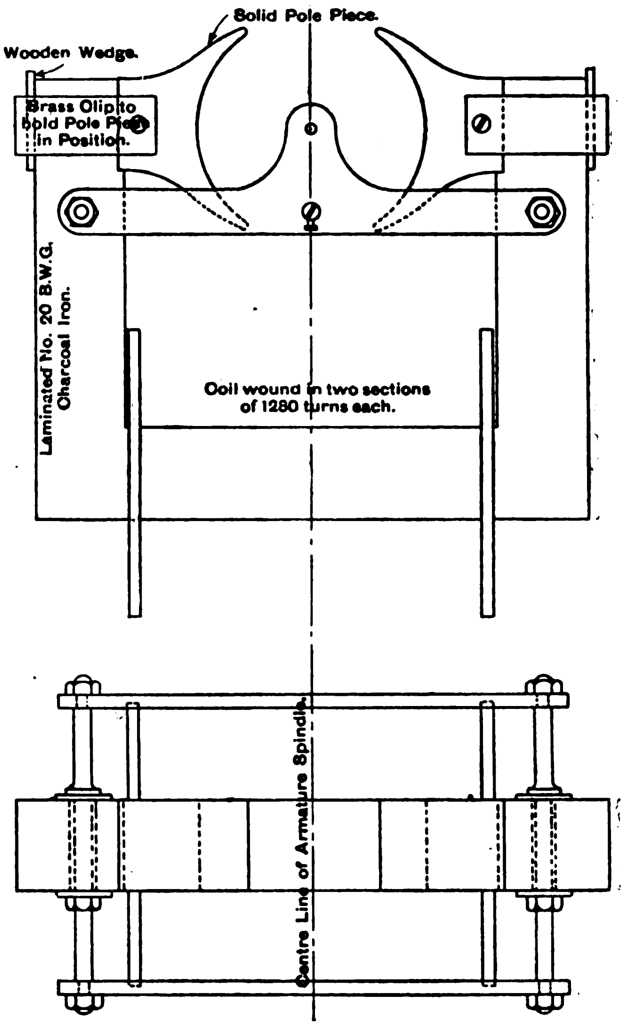

Fig. 30.

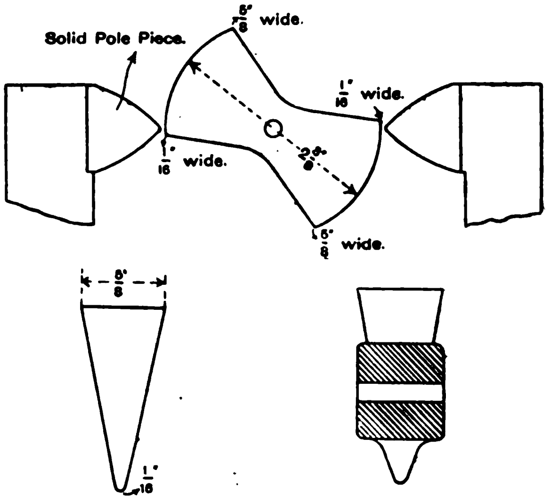
pieces and magnet limbs were carefully faced to insure good contact. The large pole-piece is shown in position in the drawing, and the remaining pole-pieces are shown in Figs. 31 and 32.



Surface of end of Armature. Section through centre of Armature.

Fig. 31.—Knife Edge Pole Pieces and Small Solid Iron Armature.

Two coils were wound on the yoke, each containing 1,280 turns No. 26 d.c.c. copper wire. It was found necessary to use one coil only, as when the two coils were coupled in series there were too many ampere-turns, consequently the inner coil,

Digitized by Google

of 18 ω resistance, was used in all experiments. The armature bearings were carried by the bolts passing through and insulated from the limbs, and were made of brass.

The result of the first experiment is plotted on Fig. 33, curve *a*, and was obtained with the small solid iron armature and knife-edge pole-pieces. The armature was in the position

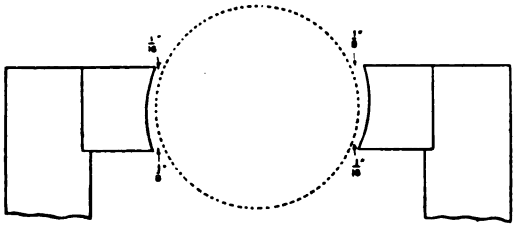


FIG. 32.—Oblique Approach Pole Piece.

shown in Fig. 31 when the pointer stood at zero. This relative position of armature and pole-pieces with the small and large armatures gave the best results, several other positions being tried. The spring in this position had an initial tension of 180deg., corresponding to a torque of 1·98 inch-ounces. Curve *b* (Fig. 33) is that obtained with the large solid armature under the same conditions as in curve *a*. The travel for a variation of

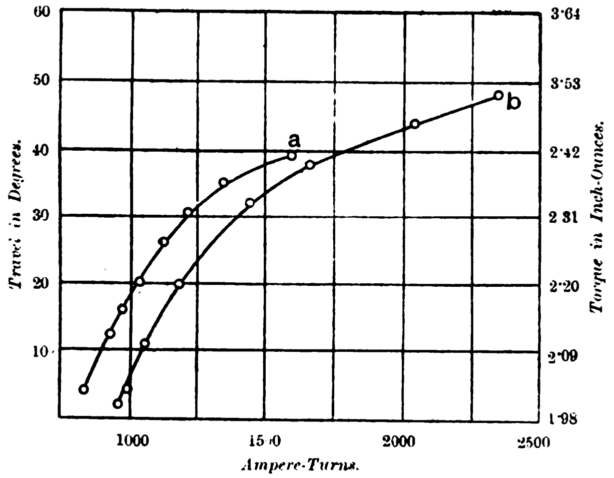

FIG. 33.

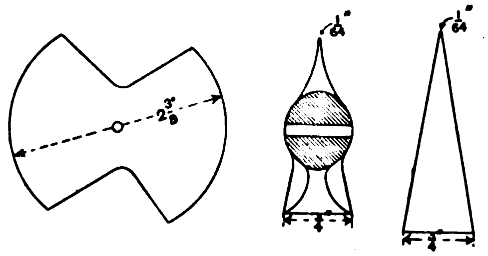
500 ampere-turns on the straightest part of the curve is 31deg. for both armatures; the maximum travel corresponding to maximum variation of excitation is 35deg. and 750 ampere-turns for the small, and 46deg. and 1,400 ampere-turns for the large armature. It would seem as if the travel of the armature was directly proportional to the length of the end surface of the armature. Of course, this is what one would expect, and it is fairly borne out by the above experiment.



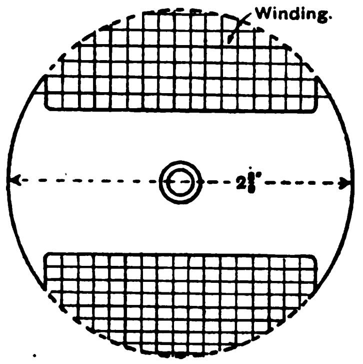
Section through centre. End surface of Armature.

FIG. 34.—Large Solid Iron Armature.

The armature used in the next set of experiments and shown in Fig. 35 was built up in a similar manner to the field-magnets, and had 500 turns of No. 26 d.c.c. wire wound in the space shown; the resistance of the winding was 6·5 ohms. The armature winding was coupled in series with the field-magnet coil, as in a series dynamo. The flat spiral spring used in the former experiments was used as a controlling force, and had an initial tension corresponding to a torque of 1·98 inch-ounces.

This armature was first tried with the knife-edge pole-pieces, and the curve obtained is given in Fig. 37A. The maximum travel for a variation of 1,500 ampere-turns was 25deg., and the curve is a fair approximation to a straight line.

The position of armature with respect to the poles is shown in accompanying sketch (Fig. 38). This position was found to give the best result.



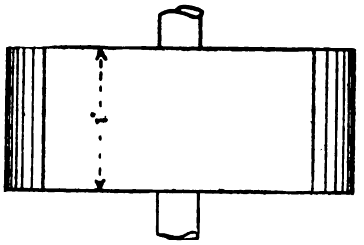


FIG. 35.—Wound Armature on Laminated Iron Core.

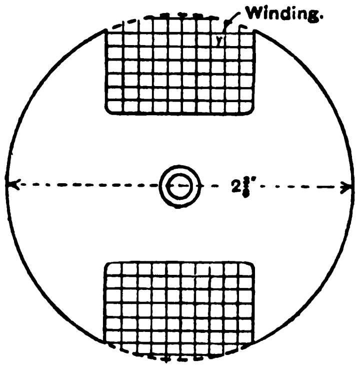
Next, the circular pole-pieces were used, and the two curves obtained are shown on Fig. 37, *b* and *c*. Inspection of these curves makes it apparent that the apparatus thus arranged is quite unsuitable for the purpose in view. Several positions of the armature with respect to the poles were tried, but that sketched (Fig. 39) gave the best results.



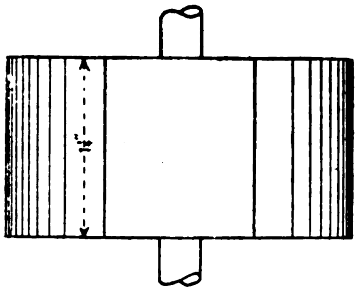


FIG. 36.—Wound Armature on Wooden Core.

In curve *b* the spring had the same tension as in *a*, and in *c* the tension was increased to give a torque of 3·96 inch-ounces at the start. In the curve *b*, for a maximum variation of 1,780 ampere-turns the travel was 77deg., while the useful or straight part is only 11deg. for a variation of 1,500 ampere-turns. The respective maximum values for *c* were 1,800 ampere-turns and

Digitized by Google

74deg., while the useful travel was 6deg. for 1,500 ampere-turns variation.

Although this piece of mechanism is not suitable for our present purpose, it is obviously useful where on closing the circuit a long travel, combined with strength and quickness, is

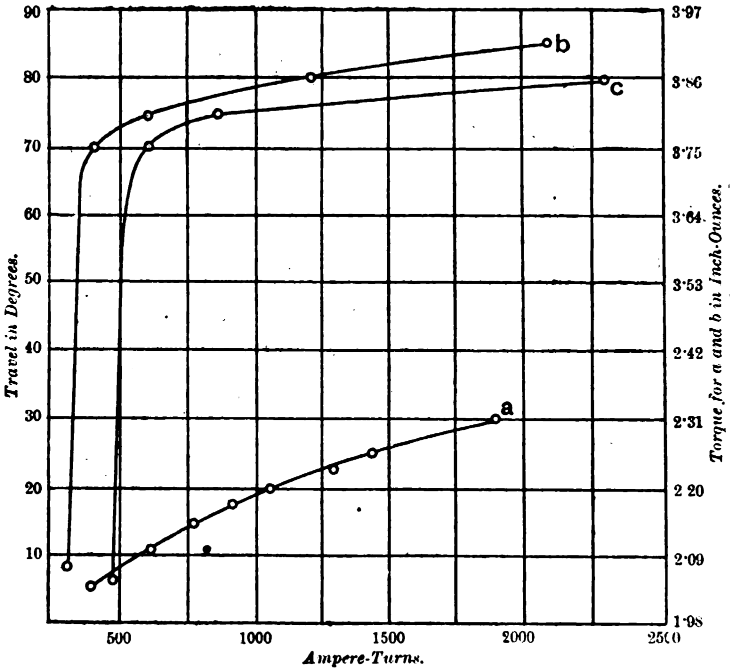

Fig. 37.

desired. The first part of both *b* and *c* curves makes this apparent, as a movement of 60deg. is obtained for a variation of 100 ampere-turns.

While experimenting with this armature and pole-pieces several positions were tried to obtain the best result as regards a rapid travel for minimum variation irrespective of the shape

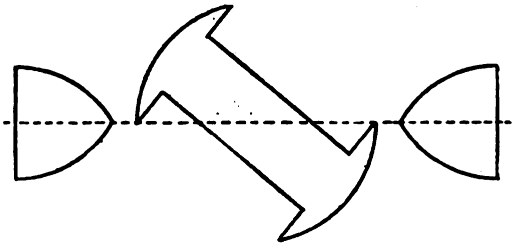

Fig. 38.—Position of Armature with respect to pole pieces when pointer was at 0.

of the curve; that sketched (Fig. 40) gave the best result with this particular armature and poles. With an initial tension corresponding to a torque of 1·98 inch-ounces the travel for a variation of 34 ampere-turns was 90deg.

In the last experiments made with this return magnetic circuit mechanism the wound armature with wooden core

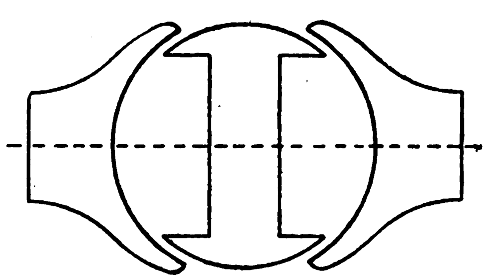

Fig. 39.—Position of Armature with pointer at Zero.

(shown on Fig. 36) was used. This armature was very similar to the last, but had not quite so much winding, having 500 turns of No. 26 d.c.c. copper wire and 6 ohms resistance. With the pointer at zero the spring had no initial tension, as experiment proved that the mechanism with this armature was not as strong as when the iron-cored armature was used. The curves obtained are given on Fig. 41, *a* and *b*; in *a* the knife-edge poles were used, and for a maximum variation of 1,700 ampere-turns the travel was 43deg.; in *b* with the circular poles the travel for the maximum of 1,750 ampere-turns was 96deg.

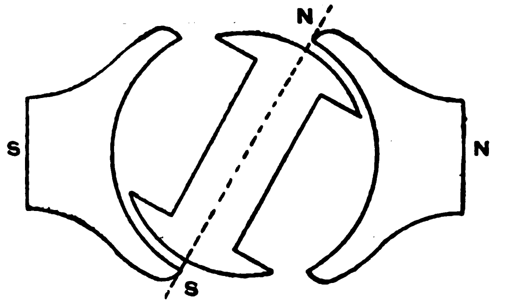

Fig. 40.

The useful travel in this case was 68deg. for a variation of 850 ampere-turns, as against 29deg. for the same variation in *a*.

The pole-pieces shown (Fig. 32) were tried, but the results were of no value, as the travel was insignificant. Mention is

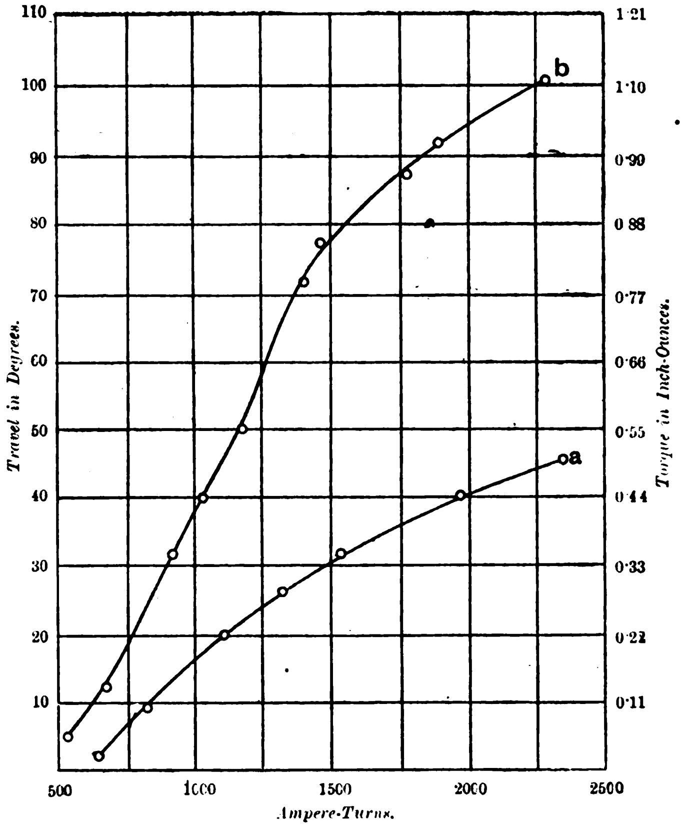

Fig. 41.

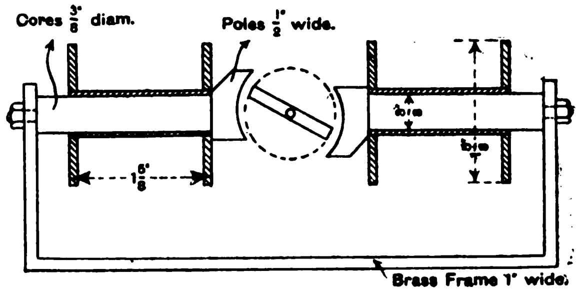

Fig. 42.

made of these poles, as the best results were obtained with the same shape without a return magnetic circuit.

In all the experiments with a return magnetic circuit the mechanism was very sluggish—*i.e.*, it did not respond to the alteration in the ampere-turns—and as this was one of the chief objects in view, the experiments that follow with an open

D

Digitized by Google

magnetic were tried, and were, on the whole, the most successful from every point of view.

The first experiment tried was with the mechanism shown (Fig. 42), and needs very little explanation. Two round cores

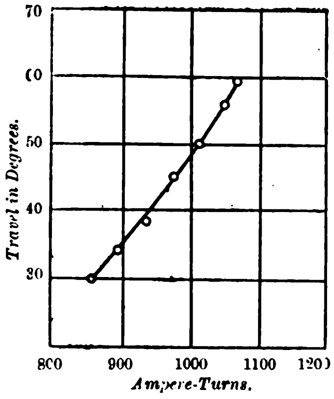

FIG. 43.

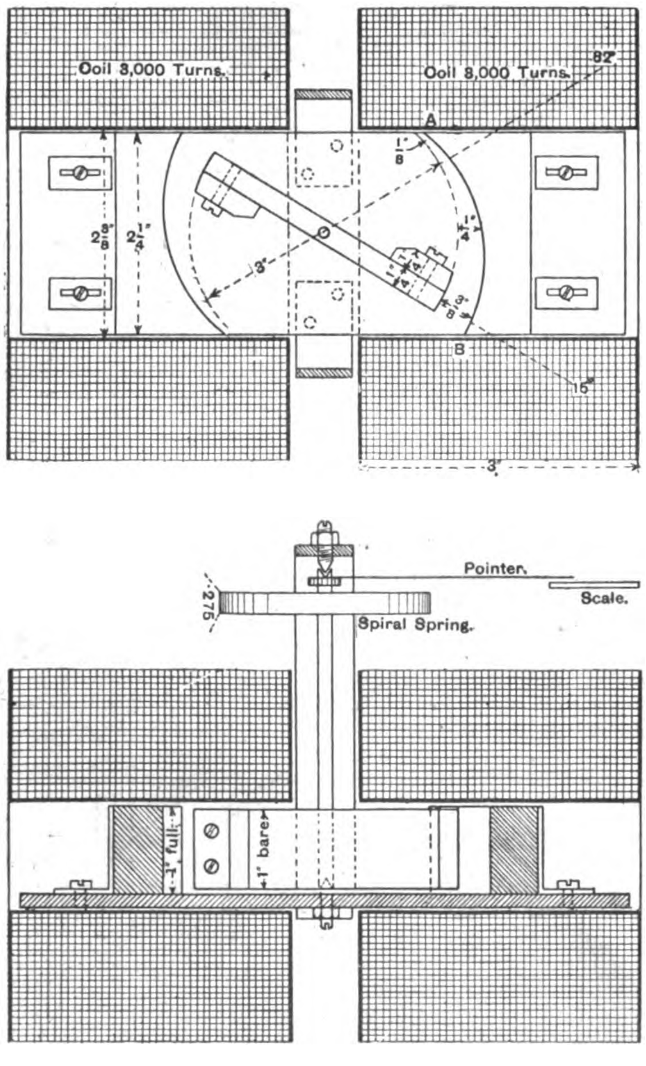
of Lowmoor iron $\frac{5}{8}$in. diameter had pole-pieces screwed on the ends, and were supported at the other ends by the brass bracket shown 1in. wide by $\frac{1}{8}$in. thick. To this bracket was screwed, at right angles, a smaller ⊔ bracket, having pivots which formed



Section through Centre.

FIG. 44.

the bearings for the armature spindle. The coils were slipped over the cores, and were wound with No. 32 platinoid wire, double-silk covered; each coil had 3,100 turns, and a resistance of 1,300 ohms. The controlling spring was arranged as in the last-mentioned experiments, and was very weak, being the mainspring of an ordinary lever watch. The pole-pieces were $\frac{1}{2}$in. wide by $\frac{3}{4}$in. long, and were bored out eccentrically to the centre of the armature spindle. The dotted circle (Fig. 42) is the path of the armature; the smallest air gap between the end of the armature and the pole was $\frac{1}{16}$in., gradually increasing to $\frac{1}{8}$in. at each side. It is evident that the mechanism worked on the principle of decreasing the air gap, and consequently the pole-pieces were so shaped that for each degree moved through by the armature the length of the air gap was decreased a proportionate amount. The armature was simply a piece of soft iron, $\frac{1}{2}$in. wide and $\frac{1}{8}$in. thick, with a spindle $\frac{1}{16}$in. diameter passing through, to which the pointer and spring were attached.

The curve obtained with this apparatus is given in Fig 43, and is almost a straight line; in fact, if the pole-pieces had been more accurately shaped on the lines laid down above, the curve would have been a perfectly straight line. For a variation of 210 ampere-turns the travel was 30deg., which is a far better result than any of the preceding. As to sensitiveness, the mechanism was as sensitive as the voltmeter.

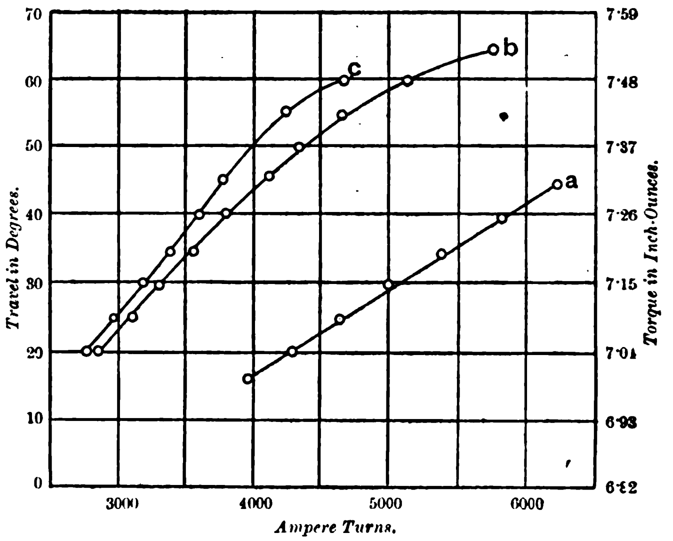


FIG. 45.

The result of this experiment was so encouraging that a much larger apparatus was made upon exactly similar lines, but the coils, instead of being wound on cores, were wound over the pole-pieces to save space.

The large open magnetic circuit mechanism is shown in plan and section through centre of the polar faces (Fig. 44). The armature was made of Lowmoor iron 1in. (bare) wide, $\frac{1}{4}$in. thick and 3in. diameter. The thickness of the armature could be increased to half-an-inch by the piece of iron shown held in position by brass screws. The armature was fixed to a spindle $\frac{3}{16}$in. diameter and supported vertically on pivots, as shown. The bottom pivot went through the brass base plate and the top through the brass bracket, to which the free end of the spiral spring was also secured. The pole-pieces were secured to the brass base plate by brass knees with slots to allow the length of the air gap to be varied. The poles were $2\frac{1}{4}$in. and 1in. (full) wide, and were bored out from two different centres, chosen so that the length of the air gap at A was $\frac{1}{8}$in. long and at B $\frac{3}{8}$in. long. Thus the length of the gap decreased in a ratio directly proportional to the angle turned through by the armature; the polar faces embraced an arc of 67deg., and in the middle, or 33·5deg. from B, the length of the air gap was $\frac{1}{4}$in. The coils were wound on copper bobbins, had an oblong hole $2\frac{3}{8}$in. by $1\frac{3}{16}$in. in the centre, and were slipped over the pole-pieces, the distance between the two coils being only $\frac{3}{4}$in. In this way the armature and poles were completely covered by the coils, and the waste lines of force were reduced to a minimum. Each coil had 3,000 turns No. 26 d.c.c. wire, and the total resistance warm was 143 ohms. When the outside edge of the armature was in line with the edge of the pole-piece at B the pointer stood at 82deg.; this enables the

Digitized by Google

position of the armature to be followed in its course on reference to the respective curves.

The result of the first set of experiments with this piece of mechanism is given on Fig. 45, curves *a*, *b*, and *c*, and shows the effect of using different springs, also increasing the thickness of the armature at the extremities. In *a* the spring was ·183in. × ·0145in. × 24in. long, and in *b* the spring used before (·275in. × ·013in. × 36in.); in the former a maximum travel of 29 deg. for 2,200 ampere-turns, and for 2,000 ampere-turns the travel 26deg., the curve being a perfectly straight line; in *b* the maximum travel was 45deg. for 2,900 ampere-turns, and for 2,000 ampere-turns variation the travel was 38deg. (straight part of the curve). Increasing the width of the armature, as shown Fig. 44, and under exactly similar conditions to *b*, the travel in *c* was 40deg. for the same variation. Thus a better result was obtained by increasing the thickness of the armature.

The next and final experiment with this piece of apparatus was made with a view to determine the best degree of eccentricity of the air gap. The curves are given on Fig. 46, *a* and *b*, and are similar to *b* and *c*, Fig. 45, but the slightly longer travel is due to the curve starting earlier.

In *a* the maximum travel is 40deg. for a variation of 2,900 ampere-turns, and in *b*, for a variation of 2,400 ampere-turns, the travel is 40deg.; this increased travel is due to the armature

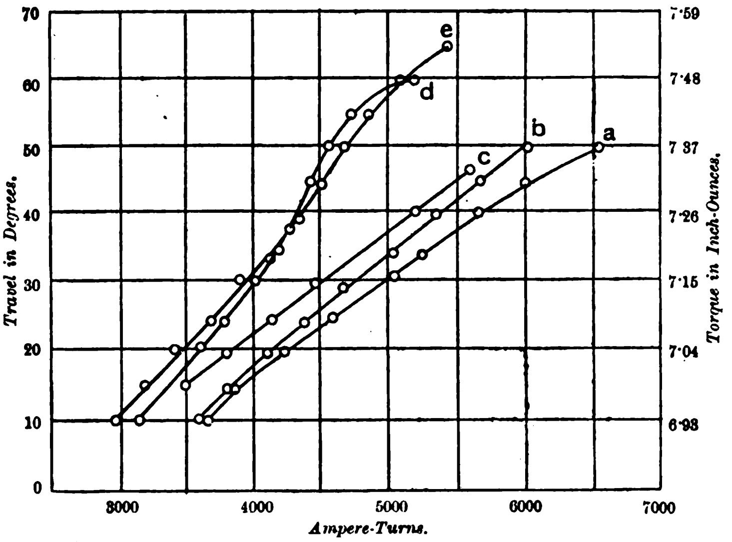

FIG. 46

being thicker. Taking the straightest part of the curve in both cases, for a variation of 2,200 ampere-turns the travel was 31deg. in *a* and 35deg. in *b*; from this it would seem that the thick armature was better suited for the purpose than the thin one.

In the curves *c*, *d*, and *e* the thick armature was used, and the distance between the armature and the pole-pieces was varied (at A and B, Fig. 44). In *c* the gap was $\frac{1}{8}$in. long at A and $\frac{3}{8}$in. at B. Here the travel was 31deg. for a variation of 2,100 ampere-turns, and the curve is a perfectly straight line. Changing the length to $\frac{1}{16}$in. at A and $\frac{5}{16}$in. at B, the travel was 50deg.; these lengths were then altered to $\frac{5}{16}$in. at A and $\frac{5}{16}$in. at B, and the travel was exactly the same for the 2,100 ampere-turns variation. Comparing the curves in *d* and *e*, we see that the curve *d* rises rather quickly when the armature is about the middle of its path; this seems to be due to the fact that the decrease in the length of the air gap was not proportional over the whole length of the travel, it being proportionately shorter at this point. The curve *e* is not quite a straight line, and the slight rise is due to the same cause. The length of the air gap was designed to proportionately decrease when it was $\frac{1}{8}$in. at A and $\frac{3}{8}$in. at B, and in this instance the curve is straight, although the travel is somewhat shorter.

It seems that by decreasing the length at A and increasing it at B, being careful that a proportionate increase was maintained from A to B, that a longer range and a perfectly straight line could be obtained. However, this was not tried, and the experiments here came to a close.

The results are tabulated (Table VI.), and require no further comment:—

Table VI.

Reference to curve.	Maximum travel in degrees	Maximum variation in amp.-turns.	Comparative travel and corresponding variation in ampere-turns.		Remarks.
			Travel.	Variat'n.	
Fig. 33 *a*...	35	750	31	500	Small solid armature and knife-edge pole-pieces.
b...	46	1,400	31	500	Large solid armature and knife-edge pole-pieces.
37 *a*...	25	1,500	25	1,500	Wound armature (iron core) and knife-edge pole-pieces.
b.	77	1,780	11	1,500	Wound armature (iron core) and circular-edge pole-pieces.
c...	74	1,800	6	1,500	Wound armature (iron core) and circular-edge pole-pieces (stronger spring).
41 *a*...	43	1,700	29	850	Wound armature (wooden core) knife-edge pole-pieces.
b..	96	1,750	68	850	Wound armature (wooden core) circular-edge pole-pieces.
43......	30	210	30	210	Open magnetic circuit eccentric pole-pieces (small apparatus).
45 *a*...	29	2,200	26	2,000	Open magnetic circuit eccentric pole-pieces (large apparatus).
b...	45	2,900	28	2,000	Open magnetic circuit eccentric pole-pieces (large apparatus).
c...	40	2,000	40	2,000	Open magnetic circuit eccentric pole-pieces (thick armature).
46 *a*...	40	2,900	31	2,200	Open magnetic circuit eccentric pole-pieces.
b...	40	2,400	35	2,200	Open magnetic circuit eccentric pole-pieces (thick armature).
c...	31	2,100	31	2,100	Open magnetic circuit eccentric pole-pieces, air gap $\frac{1}{8}$in. at A & $\frac{3}{8}$in. at B.
d...	50	2,100	50	2,100	Open magnetic circuit eccentric pole-pieces, air gap $\frac{1}{16}$in. at A & $\frac{5}{16}$in. at B.
e...	55	2,450	50	2,100	Open magnetic circuit eccentric pole-pieces, air gap $\frac{5}{64}$in. at A & $\frac{5}{16}$in. at B.

In conclusion, it may be said that the simple core and solenoid as arranged in the first experiment is not at all suitable where long range combined with strength and sensitiveness are required. There the weight of the core is supported by the magnetic field. This weight takes away a certain amount of the strength of the arrangement. It may be argued that the core could be supported and pull against a spring, but this arrangement makes the mechanism too bulky for most purposes. If a core and solenoid is used at all it seems from the results of the experiments on the circular-shaped cores and short coils that this form is more satisfactory, but to obtain a long range it is necessary to use a long core, and to keep the size of the mechanism within reasonable limits it is necessary to make the core embrace an arc of about 300deg.; then it acts like a heavy flywheel, and gives the arrangement so much inertia that it is not the least dead-beat, and although it may be sensitive to the variations in the excitation, the core does not settle down in its new position before another change in the ampere-turn takes place.

Coming to the arrangement with a return magnetic circuit, although possessing great strength for its size, the sluggishness of the mechanism makes it quite unsuitable for the purpose in view. The mechanism that embodies all the conditions laid down in the commencement, viz., maximum range, strength, and sensitiveness, for a minimum variation of excitation, is that with an open magnetic circuit and eccentric pole-pieces. In addition to the above this apparatus has the advantage of occupying less space,

The Tesla Patents in France.—*L'Industrie Electrique* states that MM. Schneider et Cie, sole concessionnaires for France of the Tesla rotary-field patents, has issued writs against MM. Weyher et Richemond, who build Brown motors, MM. Guitton et Bertolus, who own the Oerlikon patents in France, and M. Joly, Lyons representative of the firm of Alioth, of Basle and of the Société Grenobloise, which makes a rotary-field motor.

SPECIAL NOTICE.

There will be issued as a Supplement to the next number of "THE ELECTRICIAN" (September 13th) a Fine STEEL PLATE PORTRAIT of WILLIAM STURGEON. This Supplement will be issued gratis, and complaints of non-receipt should be sent immediately to the Publisher.

NIAGARA.

The flow of verbiage that has signalised the electrical utilisation of the Falls of Ni-a-gá-ra has been in keeping with the proportions of the biggest cataract on earth; would that the word-fall were as impressive as the water-fall. The English tongue gave way beneath the strain, and many effusions that were meant to be choice specimens of declamatory rhetoric resembled nothing so much as the mouthings of a foreigner in the throes of a new language. "I sometimes think," remarked a *Fortnightly* reviewer some ten or twelve years ago, "this nineteenth century, with its material progress and its mechanical inventions, its steam and its electricity, gas and patents, is being treated by the Press and its other public admirers much as the chamberlains in *Zadig* treated the Satrap. The century is hardly awake of a morning before thousands of newspapers, speeches, lectures and essays appear at its bedside, or its breakfast table, repeating as in chorus: 'Que son mérite est extrême! Que de graces! que de grandeur!' Surely no century in all human history was ever so much praised to its face for its wonderful achievements, its wealth and its power, its unparalleled ingenuity. . . . . . ." It was into some such frame of mind as this that the perpetual cataract of congratulation anent the engineering feat performed at Niagara had worked us, when we found our table groaning one morning beneath the weight of the Niagara Power Number of *Cassier's Magazine*, and with visions of yet another wearisome "cantata in honour of the age of progress," envied the table the freedom with which it could give vent to its feelings. The very first paragraph on the very first page confirmed our worst fears. "To souls sensitive to the beautiful and the sublime the plunging torrent," says Mr. FRANCIS LYNDE STETSON, "has appealed, by the stateliness of its stream, the brilliance of its boisterous rapids, and the deep glassy green of its silent foreboding brink, as well as by its drop into the seemingly infinite depth, from which there comes to him who listens the note of the welcoming abyss, deeper than the diapason of any organ's pipe."

Digitized by Google

The conception of an engineering magazine—at any rate the successful execution of the idea—must be placed to the credit of our good friends across the Atlantic. We all read nowadays—even the most rigid of "practicians"; and the generality of engineers like to know something of what is going on in those branches of the profession of which they have no special knowledge. And this not necessarily with a view of immediately or ultimately converting even light reading into hard cash, but mainly to keep in touch with the advance of each division of the Grand Army of Engineers—a touch which it is extremely difficult to maintain in these busy days, with observations accumulating like cinder heaps in the Black Country, and each man fencing in his little field of knowledge like a workman's allotment, and sticking up a notice to warn off intruders. To assist in keeping up this touch the engineering magazine has been evolved, and if the Niagara Power Number of *Cassier's* be a criterion, right well is the purpose answered. The purveyors of popular science and the writers of scientific romances are ever in danger of missing the mark either by writing far over the heads of those whom they propose to instruct or interest, or by wearying with prolix and unnecessary exposition. The difficulty experienced by the ancients in steering between Scylla and Charybdis is as nothing to that experienced by would-be popularisers of science. On the whole, we would advise them to err, if err they must, on the side of assuming a too considerable learning on the part of their prospective readers. It is flattering to one's self-esteem to be thought capable of understanding an argument or description, not a line of which is in truth comprehended. As an eminent transatlantic inventor and enthusiast once said of the, to him and to most of us, quite unintelligible lucubrations of a famous English mathematical physicist: "It does one good to be seen in their company." On the other hand, except it be a feeble and obvious witticism laboriously explained, we cannot imagine a greater insult to human intelligence than an elaborate explanation which could only have been offered on the assumption that the recipient thereof was devoid not only of understanding (that might pass), but of an elementary scientific education (that is unpardonable). Now in this matter writers in engineering magazines possess a decided advantage. They can gauge with the accuracy of a Whitworth machine the receptive capacities of their probable readers. All engineers—electrical, mechanical, civil, hydraulic and marine—at any rate start in life with much the same educational equipment; possessing some acquaintance with physical science and mathematics, and some years' experience of the workshop and drawing office. This much assumed, and the further assumption made that an article in an engineering magazine will not usually be read by experts in the particular subject treated of, but will be read by engineers of another branch, or by well-informed engineering amateurs, it would argue considerable mental myopia if the mark were often missed. In the special number to which we have alluded, the mark has been hit with unusual frequency. With scarcely an exception, the ten articles here offered up on the altar of Ni-a-gá-ra are restrained in tone, lucid in language, coherent in treatment, and illustrated, for the most part, by illustrations that illustrate. Benthamite principles have prevailed in the composition of this cantata of congratulation; the financial engineer, the hydraulic engineer, the electrical engineer, the sanitary engineer, not to mention the historically-inclined engineer, has each his allotted section; the greatest happiness of the greatest number has evidently been kept in view. The longest and by far the most interesting contribution is that by Mr. L. B. STILLWELL, of the Westinghouse Company. It is a model of what such an article should be, and, moreover, gives due recognition to the fact that the Niagara electrical plant did not spring full-matured and freshly-original from the brain of the great Pittsburg concern. There are, no doubt, many details which electrical engineers must have wished rather than have expected to see; but notwithstanding the omission of these, with the possible exception of one or two experts in big dynamo design, all electrical engineers may glean much valuable information from Mr. STILLWELL's excellent account of the plant he played such a prominent part in constructing.

Criticism of a *fait accompli*, especially when it is of an engineering order, is somewhat futile, and we do not propose to indulge in it. The Cataract Construction Company is composed of shrewd capitalists, who had the best engineering advice,—indeed, it was a matter of reproach against them that they sucked the engineering brain of Europe,—the whole work has been carried out by the best firms in the United States. It were best, therefore, to leave it to Time to justify or to condemn the general principle and engineering details of a scheme upon which such an array of talent has been concentrated. Evident it is, however, that extreme forethought characterised the general plan of the Cataract Construction Company, and extreme care and skill characterised all constructional details. Success has been deserved, even if it has not been attained.

Speculation as to what will be is perhaps scarcely more to be commended than criticism of what has been accomplished; but the revolutionary potentialities revealed by the electrical utilisation of Niagara, and the vein of five-per-cent. philanthropy running through so much of the literature concerning it, make it impossible to avoid at least a glance at the future. At the first annual dinner of the Institution of Electrical Engineers, in November of 1889, the Marquis of SALISBURY, in the course of a speech full of wit and wisdom, expressed a hope that electrical engineers, by their discovery of the electrical transmission of power, would do something towards scattering those "unnatural and often unwholesome aggregations of humanity" brought about by the mechanical engineer's discovery of the steam engine. Should the Niagara scheme develop to the extent anticipated by sanguine, but sober practical engineers like Mr. S. DANA GREENE of the General Electric Company, and should small-scale reproductions of Niagara spring up wherever possible, Lord SALISBURY's vision of men and women pursuing in their own homes many industries now requiring the aggregation of the factory, might well be within measurable distance of of realisation. The long-headed founders of the Niagara Falls Power Company, however, contemplate no such contingency. They have indeed constructed a 20th-century Utopia out of very unpromising materials and called it Echota, which being interpreted means "Place of Refuge," but although they are prepared for such an innovation as a healthy, pretty, clean, clear-aired, industrial town, the factory system is still to be supreme. Electricity, if it succeeds in effecting even such a comparatively moderate improvement as this, will have done an appreciable something in redressing the evils brought about by steam. The interesting question is whether factories and factory towns, when deprived of their soot and squalor, may not prove sufficiently satisfactory to those gathered within them to exclude all wish for the realisation of Lord SALISBURY's dream. Its realisation would in any event prove economically difficult: without the motive power of misery it might be impossible. The half-way house will have been made so comfortable that no one will want to continue the journey.

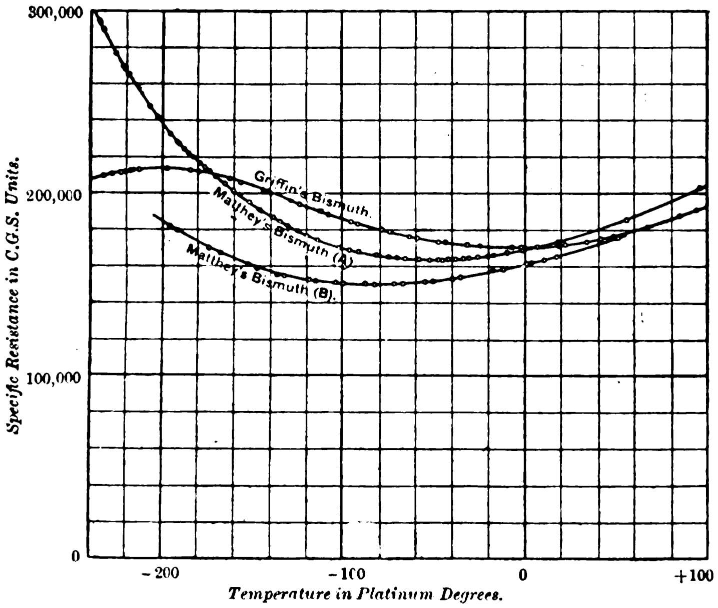
THE VARIATION IN THE ELECTRICAL RESISTANCE OF BISMUTH, WHEN COOLED TO THE TEMPERATURE OF SOLID AIR.*

BY PROF. JAMES DEWAR, F.R.S., AND PROF. J. A. FLEMING, M.A., D.SC., F.R.S.

In the course of investigations on the electrical resistance of pure metals and alloys at low temperatures made during the years 1892 and 1893, the results of which were communicated to the *Phil. Mag.*,† extensive examination was made by us of the variation in specific electrical resistance exhibited by most of the ordinary metals when cooled to temperatures approaching the absolute zero. In the course of this research the abnormal behaviour of bismuth with regard to its variation of specific resistance with temperature was noted, and in a further research on the thermo-electric powers of metals and alloys at low temperatures, the results of which were communicated to the *Phil. Mag.* recently,‡ it was noticed that the curves representing the thermo-electric power of bismuth, both for pure and for commercial specimens, presented a discontinuity at temperatures lying between about −70deg. and −100deg. We were therefore recently led to make a more careful examination of the variation of electrical resistance of bismuth when cooled down to the temperature of solid air, some of the results of which are of sufficient interest to communicate, although the investigation is still in progress, and much remains to be done to complete it.



The Variation of Electrical Resistance of Bismuth with Temperature.

A sample of very pure bismuth was kindly prepared for us by Mr. George Matthey, by the reduction of the oxide, an analysis of which showed very small traces of iron as the only impurity. This bismuth, which was the same as that used by us in our thermo-electric experiments, was pressed into wire by a steel press, two sizes of wire being prepared, one having a diameter of about 0·067cm., and the other a diameter of 0·049cm. Lengths of these wires were mounted up in an appropriate form for taking the electrical resistance when measured in liquid or in solid air, or at any other temperature up to +100°C.

Amongst other specimens a wire was pressed from some commercial bismuth, supposed to be fairly pure, which will be distinguished by being called Griffin's bismuth; the diameter of this last wire was about 0·066cm. The diameters of these wires were carefully measured with a microscope-micrometer in about twenty different places, the lengths of the wires used being about 30cm. or 60cm. The sample of pure bismuth prepared for us by Mr. George Matthey will be distinguished by speaking of it as Matthey's bismuth, the thicker of the two wires being called A and the thinner B. The dimensions and mean diameters of the pressed wires, which were used just as they came from the press, were as follows:—

Sample.	Length. Centimetres.	Mean diameter. Centimetres.
Matthey's bismuth (pure), A	61·25	0·06713
Matthey's bismuth (pure), B	32·70	0·04926
Griffin's bismuth	52·90	0·06625

In addition to these samples of pressed wires, other specimens were prepared by drawing melted bismuth up into fine glass tubes and making a suitable connection with the bismuth for the purpose of an electrical resistance measurement by means of tinned copper wires melted in to the ends of the bismuth specimen. These samples of bismuth then had their electrical resistance measured with a Wheatstone bridge in the usual way, the temperature of the specimen being taken at the same time by means of a platinum thermometer, consisting of a platinum wire closely in contact with the specimen of bismuth. All the temperatures which are given in the following paragraphs have been converted into platinum temperatures, taken in terms of our standard platinum thermometer P_1, the electrical constants of which were given by us in the Paper on the Thermo-electric Powers of Metals (see *Phil. Mag.* July, 1895). Temperatures so measured are distinguished by the letter P_1 placed after the number denoting the temperature. The electrical resistance of the bismuth specimens, all proper corrections being made for the resistance of the connecting wires, was taken at a large number of temperatures lying between the boiling-point of water (100°C.) down to the temperature of solid air, which, in terms of our standard platinum thermometer P_1 is about −233deg. P_1 to −235deg. P_1. From the known dimensions of the bismuth wires the volume specific resistance of the metal was calculated at these different temperatures.

The above numerical results are set out in the form of three curves. It will be seen that the specific electrical resistance of all the bismuth specimens taken from 100°C. downwards gradually diminishes to a point which, in the case of the specimen of pure bismuth "A" was about −50deg. P_1, and in the case of the specimen "B" about −83deg. P_1. After these temperatures had been reached, further cooling *increased* instead of diminishing the electrical resistance of the A and B bismuth, until, at the lowest temperature reached by the employment of large quantities of solid air, the electrical resistance of the specimen "A" had become increased by nearly 80 per cent. of its minimum resistance, and at the same time the mean temperature coefficient had become very large, and of course negative.

It may be noted that the melting point of solid air, as determined by our standard platinum thermometer, is −232·2deg. P_1, liquefaction taking place under a pressure of 14mm. of mercury. The boiling-point of liquid air under a presure of 746mm. is −209·75deg. P_1.

The same general facts were observed in the case of the specimen of pure bismuth "B," only in this instance the temperature was not taken below about −200deg. P_1. As regards the commercial bismuth (Griffin's) the curves show that after reaching a minimum point, which for that specimum appears to occur at about 0°C., there is another point of inflection in the resistance curve in the neighbourhood of −200deg. P_1, after which the resistance again diminishes.

In the case of each of these specimens the resistance measurements were repeated many times, and in both directions, to obtain an assurance that the relation of resistance and temperature was perfectly definite, and that proof might be obtained that all the three specimens of pressed bismuth wire, as well as the bismuth melted in the tubes, did not undergo any permanent change in their condition by the action of the low temperature, but that there was a definite relation between temperature and electrical resistance in the manner shown in the curves.

Similar experiments made with pure antimony drawn up into glass tubes did not show the appearance of any minimum resistance for any temperature between 0° and −200° P_1. In no other case amongst all the metals and alloys examined by us has any phenomenon presented itself similar to that shown by the above specimens of pure bismuth. So far, therefore, at these investigations have gone they show that the behaviour of bismuth at low temperatures in respect of electrical conductivity is anomalous. The temperature-resistance curves of these specimens are quite different to those of other pure metals.

In our first communication on the electrical resistance of metals (see *Phil. Mag.*, October, 1892), we showed that carbon taken in the form of a carbon filament from an incandescent lamp increases its resistance continuously when cooled down to the boiling point of oxygen, and we suggested that for pure non-metals continual lowering of the temperature towards the absolute zero would in all probability continually increase the specific electrical resistance. In

Digitized by Google

the specimens of pure bismuth A and B there is no indication at the lowest temperature reached, - viz., 235° P_1, that the resistance lines for this pure bismuth would have another point of inflection. If, then, the specific resistance of these samples of pure bismuth goes on increasing continuously down to the absolute zero of temperature, as it would appear to do, in that respect they behave like a non-metal, having, however, a very much larger temperature coefficient than carbon.

The behaviour of bismuth in a magnetic field in regard to electrical resistance, and also the fact that different specimens of bismuth have in some cases positive and in other cases negative coefficients at temperatures above 0°C., has been examined by other observers. Without entering into any historical statement of the course of investigation in this matter, brief reference may be made to two Papers on this subject which have a bearing on the facts here described by us. In 1886 an experimental study of the influence of magnetism and temperature on the electrical resistance of bismuth, and also of its alloys with lead and tin, was described by M. von Aubel (see *Phil. Mag.*, 1888, 5th series, Vol. XXV., p. 191). He studied the electrical resistance of certain specimens of pure bismuth in the form of rods slowly cooled, and for temperatures between 17·2°C. and 70·8° C. found a negative coefficient for some of these specimens. In the case of rods of pure bismuth, which had been tempered between temperatures 15·2°C. and 69·7°C., he found a positive temperature coefficient within these limits; that is to say, in the first case heating the bismuth decreased its resistance, and in the second case heating the bismuth increased its resistance between the stated limits of temperature. In none of the samples of bismuth examined by us have we found a negative temperature coefficient for temperatures above 0°C. For a certain specimen of compressed bismuth wire M. von Aubel found the resistance practically constant between 16·8°C. and 76°C.; but on melting, cooling, and annealing the same specimen it acquired a positive temperature coefficient between these limits. M. von Aubel examined the electrical resistance of certain bismuth-lead-tin alloys, and he came to the conclusion that the cause of these anomalies in the temperature coefficient of bismuth was the varying physical condition of the bismuth, and not the presence of impurities.

In 1894 Mr. J. B. Henderson published a Paper on "The Effects of Magnetic Fields on the Electric Conductivity of Bismuth" (see *Phil. Mag.*, 1894, 5th series, p. 488), and he gives a series of curves showing the temperature variation of bismuth when taken in magnetic fields of different strengths. For a certain specimen of bismuth wire, and for a certain magnetic field strength of about 10,000 C.G.S. units, his curves indicate a point of minimum resistance for the bismuth. Taking the bismuth at a certain temperature, the temperature coefficient at that point in a zero magnetic field was found to be positive; but on gradually increasing the strength of the magnetic field in which the bismuth was immersed the temperature coefficient finally became negative.

One point of interest, then, in connection with these investigations is whether the specific resistance of bismuth always presents a minimum value, and whether the temperature at which this minimum value occurs depends upon the strength of the magnetic field in which the bismuth is immersed as well as upon the physical condition of the metal. In the case of the two wires of pure bismuth "A" and "B" used by us, the diameters of the wires were different, and the pressures under which they were formed, and therefore the physical condition in the interior of the wire was no doubt also different. Hence, although both these wires present a point of minimum electrical resistance, the temperature at which this occurs is not identically the same. Another point of interest is that the temperature at which a discontinuity was found by us in the thermo-electric line of the pure bismuth, and which was found to be about −80°C., is also approximately the point at which the resistance-temperature coefficient of the same bismuth becomes sensibly negative. It is therefore clear that at this temperature a critical point is reached for this particular sample of bismuth, and below this point the bismuth undergoes a physical change which affects its thermo-electric value as well as its resistance-temperature coefficient. These investigations indicate that the electrical behaviour of bismuth in certain states at and below particular temperatures is irregular, and that further study is necessary to arrive at a complete explanation of the facts. It has been pointed out by one of us (*see* Friday Evening Discourse at the Royal Institution, by Prof. Dewar, "On the Scientific Uses of Liquid Air," January 19, 1894; see also *The Electrician*, July 12, 1895, p. 361) that the tensile strength of very many metals is greatly increased by cooling them down to the temperature of liquid oxygen, but that there is a very marked decrease in the tensile strength of bismuth, as well as of antimony and some other metals when taken down to the same low temperature. It is interesting to note that bismuth, which, at any rate in certain states, presents the anomaly of a discontinuity in its curve of thermo-electromotive force at a certain low temperature, has also at about the same temperature a change of sign of the temperature coefficient, and becomes, in addition, exceedingly brittle below that temperature.

In an interesting Paper on "The Mechanism of Electrical Conduction" (see *Phil. Mag.*, Ser. 5, 1894, Vol. XXXVIII., p. 57), Dr. C. V. Burton makes reference to our former experiments on the resistance of pure metals, and states and proves a theorem to the effect that at the absolute zero of temperature every substance must have either infinite specific resistance or infinite conductivity. In the samples of bismuth A and B we have before us a material which exhibits, as far as we can judge, a tendency in its specific resistance to continually increase as it is cooled to temperatures lying below about − 80deg. In this respect it resembles a non-metal, and the question arises whether this is the proper characteristic behaviour of pure bismuth, or whether in any other physical condition it would show the normal quality of pure metals in decreasing its specific resistance regularly as it is cooled towards the absolute zero. With the object of ascertaining this we have also tested some very pure bismuth kindly sent to us by Mr. Edward Matthey, and which was prepared by the reduction of the oxychloride. This being pressed into wire was found to give a resistance-temperature curve very similar in general form to that marked Griffin's bismuth. The resistance decreased down to about 0°C., and then increased again when cooled to about −160°, and finally decreased again. It is clear, therefore, that the specimens of bismuth—viz., that prepared for us by Mr. George Matthey from the oxide, and that prepared by Mr. Edward Matthey from the oxychloride, and which are both very pure—behave quite differently at very low temperatures with regard to their electrical conductivity. We have also examined the variation of a sample of bismuth prepared electrolytically, but the result of this examination we reserve until the observations have been confirmed on other samples of electrolytic bismuth.

One fact of considerable interest has presented itself in studying the action of a magnetic field on the electrical resistance of bismuth cooled to low temperatures. It is well known that the electrical resistance of bismuth is increased by being immersed in a magnetic field. Taking a sample of the pure (Matthey) bismuth wire, we measured its electrical resistance at 18°C. in the earth's field, and when placed transversely in the field of an electromagnet, and found an increase of resistance due to the field in the ratio of 1·361 to 1·434, or about 5 per cent. The same sample was cooled in liquid oxygen, and measured again in the same fields. The resistances were then in the ratio of 1·478 to 1·858. The increase in resistance in this last case is nearly 25 per cent. Hence the cooling of the bismuth to − 182°C. increased the effect of a given magnetic field in altering its resistance about five times.

Another experiment was made to ascertain whether increased pressure on the surface of the bismuth affected its resistance. When a sample of pure bismuth wire was subjected to an external surface pressure of 300 atmospheres, a very slight but definite increase of resistance was found, which disappeared instantly on removing the pressure.

The above-described observations show that there is a very marked difference between different samples of bismuth as regards electrical resistance when subjected to very low temperatures, and that its behaviour at these temperatures in magnetic fields is also abnormal. We propose to reserve further remarks on this subject until we have completed the experiments in progress on electrolytic bismuth. We expect then to be able to state the results obtained for specimens of bismuth of known chemical purity, and to distinguish between those effects which are due to physical condition and those, if any, arising from the presence of minute traces of impurity.

ELECTRO-DEPOSITION OF BRASS.*

BY FRANK SUTTON.

The first part of the Paper deals with the general theoretical considerations involved in electro-deposition, and with the calculation of the E.M.F. required from thermo-chemical data. The author then proceeds to recount the experiments which were carried out in the electrical engineering department of the Columbia College, and gives the methods employed for determining the resistance of the baths. Tables and curves are given. The baths employed were as follows:—Mixtures of zinc sulphate and copper sulphate solutions in equal and unequal proportions, copper sulphate and zinc chloride in the proportion of 100 copper to 60 zinc, a solution of equal parts copper acetate and zinc chloride, and equal parts of copper acetate and zinc acetate. These baths were all composed of half saturated solutions, and the only one that gave a deposit looking like an alloy was the last. But the author points out that the heats of formation of the two acetates, although nearer than those of the other salts employed, were still too far apart. A saturated solution of the cyanides of copper and zinc was then tried, and gave good results, as the heats of formation of the two

* Abstract from *Electric Power* of New York.

Digitized by Google

salts are very nearly the same. A cyanide brassing solution, used commercially, was also tried, and gave a good deposit, but not equal to that obtained from the solution prepared from pure material. The resistance of the latter was also lower.

With reference to the conditions under which copper and zinc will alloy, the author points out, in conclusion, that the local action, that is, back currents caused mainly by the counter E.M.F., tends to work towards the surface of the solution, and that this counter E.M.F. is different for alloys that are deposited from the solution, being higher for an alloy that contains more of that metal whose salt solution has the higher E.M.F. This counter E.M.F. not only depends on the solution, but also on the alloy. The alloy deposited depends upon the initial E.M.F. As the impressed E.M.F. is increased the alloy will change its proportions, these proportions depending on the velocities of the migration of ions in different salts. The amount of zinc increases directly with the initial E.M.F., and finally reaches a point where more of it is deposited than of copper. The best alloys are obtained when the initial E.M.F. exceeds the counter E.M.F. by a small amount. As the initial E.M.F. is increased the counter E.M.F. will increase, but at a much reduced rate, and this rate decreases so much that when the initial is very high the counter is negligible. Now this counter E.M.F., although it does cause a certain amount of energy to be lost, may be considered a help as far as electro-plating work is concerned, as it really throttles the current, and keeps the ions from combining too rapidly.

A THEORY OF THE SYNCHRONOUS MOTOR.*

BY W. G. RHODES, M.SC.

1. Several foreign writers, notably Steinmetz,† have given theories of the synchronous motor, but most of them, by failing to see how the analysis could be simplified, add to the difficulties of the theory by mathematical intricacies which are apparently quite unnecessary. The author offers the following attempt to present a theory of the synchronous motor in as simple a way as possible, and as the mathematics, for the most part, consist of simple algebra, the difficulties are reduced to a physical conception of the subject. Many of the results have already been obtained, and the part for which the author chiefly claims originality is the method of attacking the problem.

2. We consider the case of an alternating-current machine whose field is excited by a direct current, while a simple alternating current passes round the armature.

Let p = output of motor;
c = virtual value of armature current;
R = resistance of armature;
E = virtual value of impressed E.M.F.;
e = ,, ,, counter E.M.F. of motor;
L = coefficient of self-induction of armature;
n = frequency of armature current;
I = impedance of armature = $\{R^2+(2\pi n L)^2\}^{\frac{1}{2}}$;
S = reactance = $2\pi n L$;
ψ = phase difference between c and E;
ϕ = ,, ,, ,, c ,, e;
θ = ,, ,, ,, c ,, Ic.

Then the input $= p + c^2 R$;
and also $= c E \cos\psi$;
therefore $p + c^2 R = c E \cos\psi$.

Solving for c we get

$$c = \frac{E}{2R}\cos\psi \pm \frac{1}{2R}\sqrt{\{E^2\cos^2\psi - 4pR\}} \quad . \quad . \quad (1)$$

Since c is always real, we must have

$$E^2\cos^2\psi \geqq 4pR;$$

therefore the maximum value of p is

$$p = \frac{E^2}{4R} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

This occurs when $\psi = 0$; that is, when the current and the impressed E.M.F. are in phase with each other.

We notice that the maximum output is the same as the maximum energy which can be given to an external circuit by a generator of constant E.M.F. E. From (1) we get the corresponding value of the current

$$c = \frac{E}{2R}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

3. To find the corresponding value of e we notice that E, e, Sc and Rc reversed are in equilibrium amongst themselves; so that taking components of these along and at right angles to the direction of E, we have

$$\left.\begin{aligned} e\cos\phi &= E - Rc \\ e\sin\phi &= Sc \end{aligned}\right\};$$

and

therefore

$$\left.\begin{aligned} e\cos\phi &= 2Rc - Rc = Rc \\ e\sin\phi &= Sc \end{aligned}\right\}, \text{ from (3).}$$

and

Squaring and adding, we get

$$e^2 = (R^2+S^2)c^2 = I^2c^2;$$

therefore

$$e = Ic = \frac{IE}{2R}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

Also, by division,

$$\tan\phi = \frac{S}{R} = -\tan\theta \text{ (see Fig. 1).}$$

4. We thus find that when working at maximum output:—

(1) The impressed E.M.F. is in phase with the current in the armature.

(2) The maximum output is $p = \frac{E^2}{4R}$.

(3) The corresponding current in armature is $c = \frac{E}{2R}$.

(4) The corresponding counter E.M.F. is $e = \frac{IE}{2R}$.

(5) The angle of phase between the armature current and the E.M.F. necessary to overcome the resistance and self-induction of the armature is equal and opposite to the angle between the current and the counter E.M.F.

(6) Also from (4) we see that

$$e \gtreqless E \text{ according as } I \gtreqless 2R,$$

$$\text{that is, according as } (2\pi n L)^2 + R^2 \gtreqless 4R^2,$$

$$\text{,, \quad ,, \quad } L^2 \gtreqless \frac{3R^2}{4\pi^2 n^2},$$

$$\text{,, \quad ,, \quad } L \gtreqless \frac{R\sqrt{3}}{2\pi n}.$$

Running Light.

5. We have

$$\left.\begin{aligned} p + c^2 R &= cE\cos\psi \\ p &= ce\cos\phi \end{aligned}\right\}.$$

and

If we neglect the friction of the bearings, &c., we may, in this case, put $p = 0$; we then have

$$\phi = \pm\frac{\pi}{2}$$

and $cR = E\cos\psi$.

Hence the maximum value of c is (putting $\psi = 0$)

$$c = \frac{E}{R},$$

the same as would be produced by a constant E.M.F. E in a non-inductive circuit of resistance R.

Also, putting $\psi = \pm\frac{\pi}{2}$, the minimum current is zero.

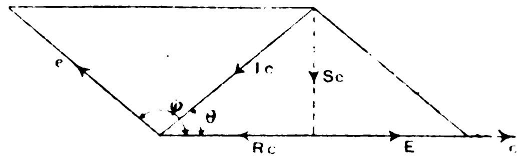

Fig. 1.

Now, from Fig. 1, we get (of course ψ is not now zero, nor does $e = Ic$)

$$E^2 = e^2 + I^2c^2 + 2Ice\cos(\phi - \theta);$$

when $\phi = \pm\frac{\pi}{2}$, this becomes

$$E^2 = e^2 + I^2c^2 \pm 2Ice\sin\theta$$
$$= e^2 + I^2c^2 \pm 2Sce, \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

since $\sin\theta = \frac{S}{I}$.

The upper sign in (5) corresponds to the machine running as a generator, and the lower as a motor.

We also see from (5) that, corresponding to $c = \frac{E}{R}$, we have

$$e = \mp\frac{ES}{R},$$

and, corresponding to $c = 0$, we have

$$e = \pm E.$$

* Paper read before the Physical Society.
† Trans. Am. Inst. Elec. Eng., December, 1894.

Digitized by Google

Now, solving equation (5) as a quadratic in c, we get

$$c = \mp \frac{eS}{I^2} \pm \frac{1}{I^2}\sqrt{(I^2E^2 - R^2e^2)} \quad . \quad . \quad . \quad . \quad . \quad (6)$$

and, as c is real, we must have

$$I^2E^2 \geqq R^2e^2$$

or

$$IE \geqq Re\,;$$

therefore the maximum value of e is given by

$$e = \pm \frac{IE}{R}$$

and the corresponding current is

$$c = \mp \frac{eS}{I^2}$$

$$= \mp \frac{SE}{RI}.$$

6. The equation $\quad e^2 - 2Sce + I^2c^2 = E^2$

is the characteristic curve of the motor running light. It may be written

$$e^2 - 2Sce + S^2c^2 + R^2c^2 = E^2,$$

or

$$(e - Sc)^2 + R^2c^2 = E^2,$$

or

$$\frac{(e - Sc)^2}{E^2} + \frac{c^2}{\frac{E^2}{R^2}} = 1,$$

which is the equation to an ellipse having as conjugate diameters the lines

$$e - Sc = 0 \text{ and } c = 0.$$

Similarly, the equation

$$e^2 + 2Sce + I^2c^2 = E^2,$$

which refers to the machine as a generator, may be written

$$\frac{(e + Sc)^2}{E^2} + \frac{c^2}{\frac{E^2}{R^2}} = 1,$$

also the equation to an ellipse. These ellipses are represented in Fig. 2.

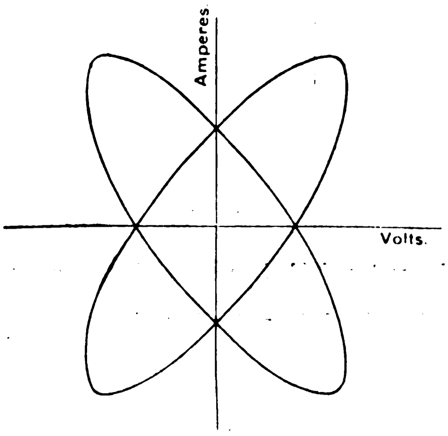

FIG. 2.

Minimum Current at Given Power.

7. We have

$$p + c^2R = cE\cos\psi.$$

The current is a minimum when $\frac{dc}{d\psi} = 0$. Now, differentiating with respect to ψ,

$$(2cR - E\cos\psi)\frac{dc}{d\psi} + cE\sin\psi = 0\,;$$

therefore, when

$$\frac{dc}{d\psi} = 0,$$

we have

$$\sin\psi = 0,$$

or

$$\psi = 0\,;$$

that is, the current is a minimum when in phase with the impressed E.M.F., as is otherwise obvious. Putting, therefore, $\psi = 0$, we have

$$p + c^2R = cE \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

This curve is of the second degree in c and p, and is satisfied by the following system of points:—

(a) $\left.\begin{array}{l} c = 0 \\ p = 0 \end{array}\right\}$ (b) $\left.\begin{array}{l} c = \frac{E}{2R} \\ p = \frac{E^2}{4R} \end{array}\right\}$ (c) $\left.\begin{array}{l} c = \frac{E}{R} \\ p = 0 \end{array}\right\}$.

That the equation is satisfied by (a) is obvious, and we see that it is satisfied by the points (b) and (c) by writing it in the form

$$\left(c - \frac{E}{2R}\right)^2 + \frac{p}{R} = \frac{E^2}{4R^2}.$$

8. Thus we see that the curve of minimum current at given power passes through the points of

(a) Zero current and zero power;
(b) Maximum power;
(c) Maximum current and zero power.

We notice that the maximum current at no load is $c = \frac{E}{R}$, whereas if the motor were at rest the current would be $c = \frac{E}{I}$; that is, the maximum current at no load is in all cases greater than the maximum current if the armature is at rest.

9. Again, from the equation

$$p + c^2R = cE\cos\psi,$$

we have

$$\psi = \cos^{-1}\frac{p + c^2R}{cE}\,;$$

therefore

$$\frac{d\psi}{dc} = \frac{c^2R - p}{c\sqrt{\{c^2E^2 - (p + c^2R)^2\}}} = 0,$$

when

$$p = c^2R.$$

ψ is then a maximum, and we see that the maximum difference of phase between the current and the impressed E.M.F. takes place when the electrical efficiency is $\frac{1}{2}$.

10. *Example.*—Suppose we have a 50-kilowatt motor driven by a 1,000-volt generator, and suppose that $R = 3$ ohms and $S = 4$ ohms, so that $I = 5$ ohms.

Then Maximum output $= \frac{10^6}{12} = 83{\cdot}3$ kilowatts;

Corresponding current $= \frac{1000}{6} = 166{\cdot}7$ amperes;

Corresponding counter E.M.F. $= \frac{5000}{6} = 833{\cdot}3$ volts;

Maximum current running light $= \frac{1000}{3} = 333{\cdot}3$ amperes;

Corresponding counter E.M.F. $= \frac{4000}{3} = 1{,}333{\cdot}3$ volts; &c.

11. To find the characteristic of the motor at any given load we must eliminate θ and ϕ between the equations

$$p = ce\cos\phi,$$

$$\sin\theta = \frac{S}{I},$$

and

$$E^2 = e^2 + I^2c^2 + 2Ice\cos(\phi - \theta).$$

The eliminant is

$$E^2 - e^2 - I^2c^2 - 2Rp = 2S\sqrt{c^2e^2 - p^2}, \quad . \quad . \quad . \quad (8)$$

which is the required general relation between e and c.

In the Paper referred to above, Steinmetz calls equation (8) the fundamental equation of the synchronous motor: the equation is there developed and plotted; results are obtained directly from equation (8), but the development is so cumbrous that the writer thinks that his simple treatment may benefit those interested in the subject of alternate-current motors.

Armature Reaction in a Single-phase Alternate-current Machine.

12. In the above analytical treatment the magnitudes only of θ, ϕ and ψ are considered. We proceed to investigate the signs of these angles in order to determine the lags or leads of the E.M.F.'s over the current, and to apply the results to find out whether the field excitation of generator and motor is strengthened or weakened by the reaction of the armature currents.

13. It will now be convenient to slightly alter the meanings of the symbols.

Let E = virtual value of generator E.M.F.;
e = ,, ,, counter E.M.F. of motor (as before);
R = total resistance in circuit consisting of generator motor and line;
L = sum of coefficients of self-induction of generator and motor armatures, or, if the line possesses self-induction, the coefficient of self-induction of the whole circuit;
I = impedance of the complete circuit;
S = reactance of the complete circuit.

14. The E.M.F. Rc, which drives the current, is the resultant of E, e and Sc; so that E, e, Sc and Rc reversed form a system of E.M.F.'s in equilibrium.

In Fig. 3 let the positive direction of rotation be counter-clockwise, and let Oc be the direction of the current. The instantaneous value of the current does not concern us at present. Take OR^1 equal to Rc reversed, and consequently opposing the current; let $OS^1 = Sc$, lagging behind the current by a quarter of a period. The resultant, OT^1, of OR^1 and OS^1 will then be equal and opposite

Digitized by Google

to the resultant of E and e. If, therefore, we produce T^1 O to T and make O T = O T^1, O T will represent in magnitude and direction the resultant of E and e. If, now, we are given the magnitudes of E and e, we can find their directions by parallelogram law. Now two parallelograms can be constructed having O T as diagonal and E, e as adjacent sides, but, since E is the E.M.F. of the generator, we take that which gives the component of E along O c in the same sense as the current. The other parallelogram would make e the generator. We may notice that the possibility of constructing these two parallelograms affords a proof of the fact that, in general, either of two alternate current machines may be driven as a motor by the other, irrespective of their relative E.M.F.'s. An analytical proof of this is given by the energy equation

$$p + c^2 R = c E \cos \psi,$$

remembering that $\qquad p = c\, e \cos \phi,$

and that ϕ and ψ are independent.

The condition that E represents the generator E.M.F. limits our choice of the two parallelograms to O E T e (Fig. 3). We then have

$$\text{angle } c \text{ O E} = \psi,$$
$$\text{angle } c \text{ O } T^1 = \theta,$$
and $$\text{angle } c \text{ O } e = \phi.$$

15. Now through T draw P S T Q parallel to the line of current and draw P M, S O, T R and Q N through e, O, T and Q respectively, at right angles to the line of current. We have

$$\tan \theta = -\frac{S e}{R e} = -\frac{S}{R} = -\frac{2\pi n L}{R}; \quad . \quad . \quad . \quad (9)$$

that is, θ is independent of the current and O T is a fixed direction relative to O c so long that the speeds of the machines are kept constant, and L is considered constant.

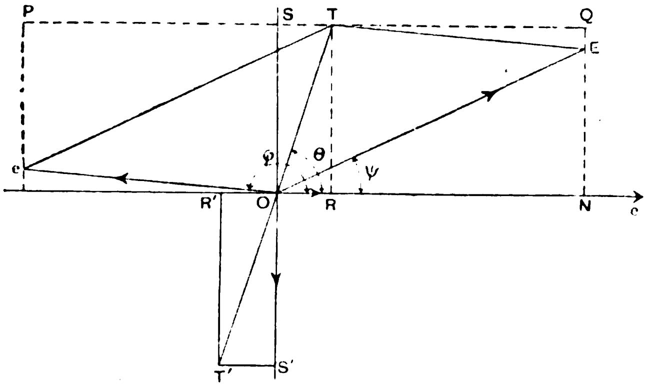

Fig. 3.

16. In Fig. 3,

O S (or P M) is proportional to the current [$= 2\pi n L c$],
O M is the component of e directly opposing c,
O R is the E.M.F. required to overcome resistance [$= R c$],
and O N is the component of E in the direction of c;

hence, rectangle P S O M is proportional to the output of the motor [p],
rectangle O S T R „ „ c^2 R losses,
and rectangle O S Q N „ „ output of generator [c E cos ψ].

From this, and the equation

$$p + c^2 R = c E \cos \psi,$$

it follows that the efficiency of transformation

$$= \frac{OM}{ON} = \frac{OM}{MR}.$$

17. If the output of the motor is kept constant, we have

$$\text{rectangle PSOM} = \text{constant},$$

and the locus of P is a rectangular hyperbola having O M and O S as asymptotes (Fig. 4).

Take any point P on this hyperbola.

We have seen (9) that O T has a fixed direction relative to O c, and the point T (Fig. 3) on this direction is found by drawing through P a line parallel to O c. Again, e lies on the line through P parallel to O S, and e T = E in magnitude.

Let the E.M.F. of the generator be kept constant and equal to E. With centre T and radius E describe a circle cutting P M in e and e^1; then the corresponding counter E.M.F. of the motor may be either O e or O e^1, and the current is represented by P M (in magnitude)—that is, corresponding to given values of E and c there are two values of e. The relative phases in the two cases are shown in parallelograms O e, T E and O e^1, T E^1 (Fig. 4).

18. To find the point P^1 on the hyperbola corresponding to minimum current (Fig. 4) we have to bring the points e and e^1 into coincidence. The point P^1 is obviously got by taking O $E_1{}^1$ equal to E and through $E_1{}^1$, drawing $E_1{}^1$ P parallel to O T. The resulting parallelogram O P^1 T_1 E_1 shows that the generator E.M.F. is in phase with the current.

19. Suppose now that the excitation of the generator field is kept constant, while that of the motor is varied.

When the motor excitation is small, as O e (Fig. 4), we see that the current leads over the motor E.M.F. and lags behind the generator E.M.F.

When e exactly opposes c, the latter lags behind E.

When E and c are in phase (minimum current) c lags behind e.

When e is still further increased, as O e^1, c leads before E, and lags behind e. This explains the condenser action of an over-excited synchronous motor noticed by Prof. S. P. Thompson and others.

20. It is known that a leading current strengthens the field of a generator and weakens that of a motor, while with a lagging current the reverse is the case.

We therefore conclude that when the excitation of the motor field is small armature reaction weakens the fields of both generator and motor, and when the motor is over-excited both machines have their fields strengthened. When working at minimum current armature reaction strengthens the motor field, and does not affect the field of the generator.

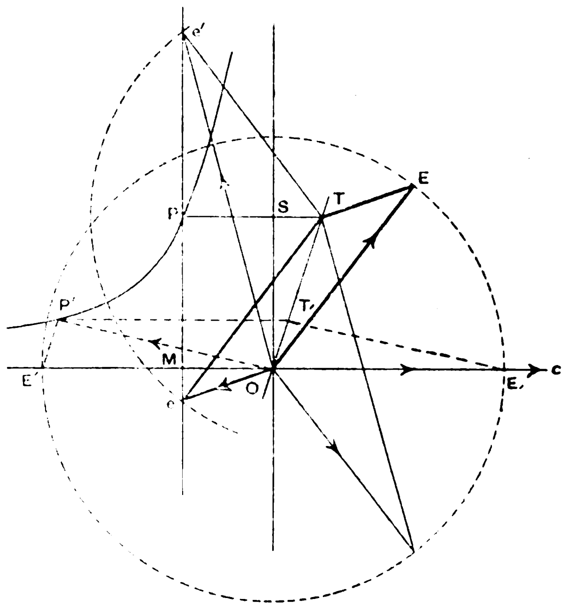

Fig. 4.

When the motor field is unaffected the generator field is weakened.

21. Now the field of the motor is, under ordinary working conditions, excited to a somewhat greater extent than is required to obtain minimum current; for, though the c^2 R losses are a minimum and the efficiency a maximum when the current is a minimum, it is advisable to increase the counter E.M.F. to a certain extent in order to cope with accidental variations of the load. Under ordinary working conditions, therefore, the effect of armature reaction is to strengthen the field of the motor and also of the generator, but to a less extent.

22. We now proceed to obtain an expression for the alteration in ampere-turns of the field excitation due to armature reaction.

Let ϕ be the displacement of phase of the current over the E.M.F. of the machine; n the number of turns of wire in one section of the armature; i the virtual current, and $i_0 \sin pt$ the instantaneous value of the current, so that i_0 is its maximum value.

It has hitherto been customary to assume that the alteration in the excitation is given by the expression

$$i\, n\, \phi, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (10)$$

where ϕ is expressed in circular measure.

Now it is not the virtual current to which the armature reaction is due, but the *mean value of the current* through an angle ϕ on each side of its maximum value—that is, the proper value of the current is given by

$$I = \frac{p}{2\phi} \int_{\frac{\pi - 2\phi}{2p}}^{\frac{\pi + 2\phi}{2p}} i_0 \sin pt\, dt,$$

$$= \frac{i_0}{\phi} \sin \phi.$$

Digitized by Google

And, remembering that $i_0 = \sqrt{2}\, i$, we get

$$I = \sqrt{2}.\, i \frac{\sin \phi}{\phi}.$$

Thus the proper expression for the alteration of the field excitation in ampere-turns is

$$2\, I\, n\, \phi,$$

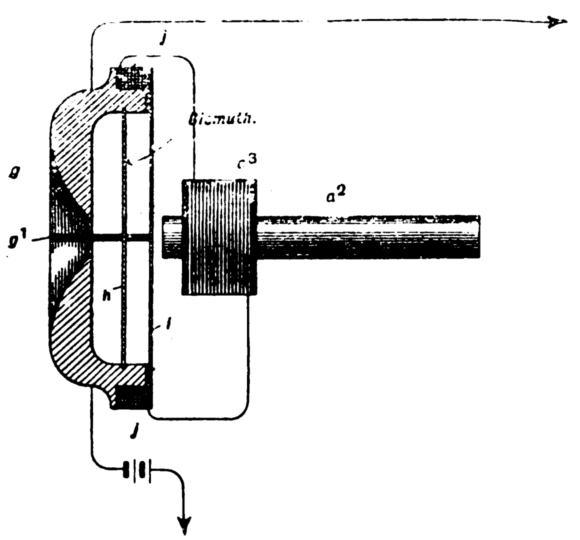
or $$2 \sqrt{2}\, .\, i\, n \sin \phi. \quad . \quad . \quad . \quad . \quad . \quad (11)$$

To find the total excitation of the field we must add expression (11) to, or subtract it from, the ampere-turns on the field, according as the current leads or lags in a generator, and lags or leads in a motor.

A BISMUTH MAGNETO TELEPHONE TRANSMITTER.*

It is well known that the electrical resistance of bismuth varies when this metal is subjected to the influence of a magnetic field, and the extent of the variation is, within limits, proportional to the strength of the field. This principle is employed in an instrument designed to determine the strength of magnetic fields, by measuring the resistance of a bismuth wire inserted therein.

The same idea has been embodied, though for a different purpose, in a telephone transmitter due to Mr. J. S. Biggar, of San Francisco, Cal. The instrument, which is illustrated in the accompanying engraving has a mouthpiece, *g*, divided into two parts, separated by insulating material *g*¹. There are two diaphragms, one *h* of bismuth and the other *i* of soft iron and of the usual construction, the latter insulated from the mouthpiece.



A Bismuth Magneto Telephone.

Between the two diaphragms is an air chamber which conducts the vibrations of one diaphragm to the other. Back of the iron diaphragm is placed the usual permanent magnet and coil. A coil of wire *j* is wound upon the mouthpiece of the instrument, and surrounds the bismuth diaphragm. This coil is in a closed circuit with the coil upon the permanent magnet. The two parts of the mouthpiece form the terminals of the main circuit, and they are bridged, as shown, by the bismuth diaphragm. It will be seen that the bismuth diaphragm is located in the magnetic circuit of the coil *j*, and that it is therefore subjected to the variations in magnetic force, which cause it to vary the flow of current in the main circuit.

EXPENDITURE OF ELECTROMOTIVE FORCE IN ELECTRO-CHEMICAL PROCESSES.†

The author points out that even after the corrections supplied by Helmholtz, Gibbs and Nernst have been applied, there is a wide discrepancy between the theoretical and the actual E.M.F. required in commercial electrolytic processes. In the electrolysis of sulphate of copper solution between copper electrodes we have an ideal case, but complications occur as soon as the extraction of copper from its ores by electrolysis is attempted. The ore may contain iron, and may be partially decomposed, so that sulphuric acid and oxygen are produced, and the current may not extract copper from the anode as rapidly as it is deposited on the cathode. Uncompensated losses occur from the oxidation of oxidisable salts; for instance, $FeSO_4$ is converted into $Fe_2(SO_4)_3$, and sulphuric acid which may be present is decomposed with the evolution of oxygen and hydrogen. Oettel has shown that even in the electrolysis of copper sulphate between copper electrodes as much as 20 per cent. of the current may be spent in producing persulphuric acid. The wasteful evolution of hydrogen constitutes the weak point in almost every electrolytic process. A comparison is made between the production of chlorine by the electrolysis of hydrochloric acid, and the decomposition of hydrochloric acid by air, aided by the contact action of copper. In the former process only 50 per cent. of the electrical energy is used, so that it requires 6½ times the weight of coal to produce the same quantity of chlorine that the Deacon process does. A great saving would be effected if the hydrogen evolved could be made to combine with oxygen and produce electrical energy which could be usefully employed. As long ago as 1839 Grove showed by his gas battery how this might be done, but the problem practically remains unsolved to this day as far as technical applications are concerned. Messrs. Mond and Langer's gas battery (*Proc.* Roy. Soc., 46, 296, 1889) is a great improvement, but the author states that it is liable to get out of order, and requires more skilled attention than can be expected from a workman. The author considers that the invention of a practical gas battery which could be fed with air and producer-gas would be a matter of great importance.

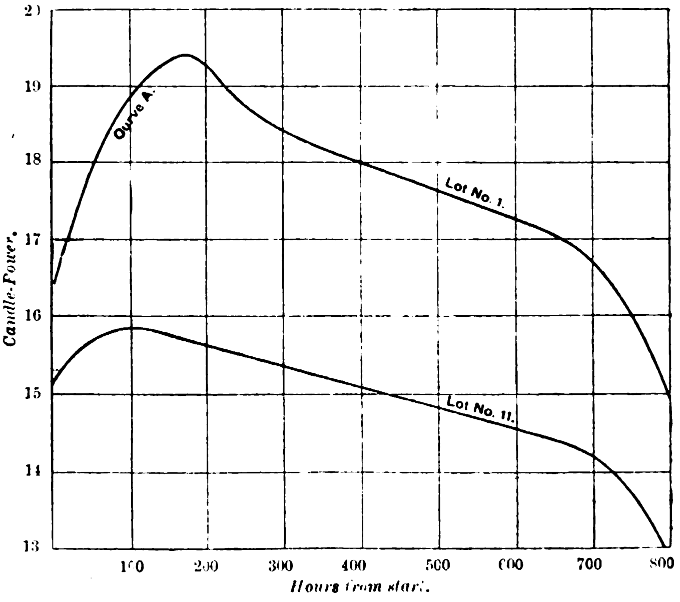
TEST OF PACKARD LAMPS.

The *Electrical Engineer* of New York has recently published a report of an exhaustive test of Packard lamps, made by Prof. B. F. Thomas, of the Ohio University, which will prove of interest to all users of incandescent lamps.

In order to test the lamps under commercial rather than laboratory conditions, arrangements were made with the local Edison electric company to carry on the test on their regular circuit where the lamps would be subjected to the same variations in voltage that they ordinarily experience in practice.



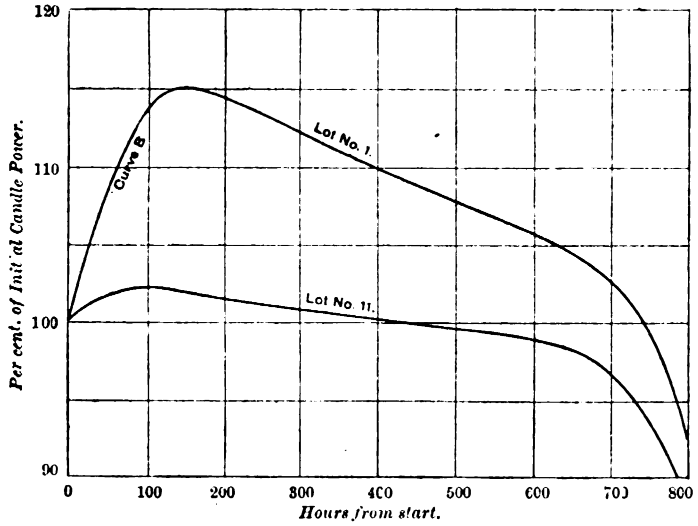
Curve "A," showing Candle-Power.

Fifty 100-volt 16 c.p. lamps were tested in two lots of 25 each. The average voltage was about 99. The photometric readings were taken with a Lummer-Brodhun photometer. The values obtained are plotted in the accompanying diagram, curve A showing the candle-power and time; curve B the percentage of initial candle-power and time, and curve C the efficiency and time.

As shown by these curves, Lot I. shows a marked increase in candle-power on the start, reaching a maximum of 17·9 candles at about 175 hours, then decreases uniformly until 600 hours, when a more rapid decrease sets in. The candle-power does not fall to its initial value of 15·54 candles until over 700 hours from the start. Lot II. shows only a moderate rise in candle-power, with a maximum at about 150 hours, and then decreases uniformly to its initial value at 400 hours. It shows also a sharp increase in declining brightness at 600 hours. This change may have been produced by strain due to abnormally high voltage at soon after the 600-hour point. Such a high voltage was observed for some time during the day preceding the evening on which the readings at 696 hours were taken, and its effect on the candle-power of

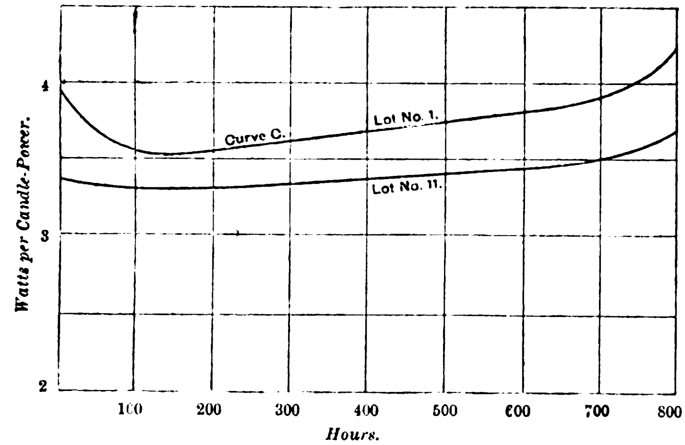
Digitized by Google

Lot I. was particularly marked, though less so than on Lot II. Curve B shows a rise of over 15 per cent. in the candle-power of Lot. I., with a final value only 6·5 per cent. below the initial value.



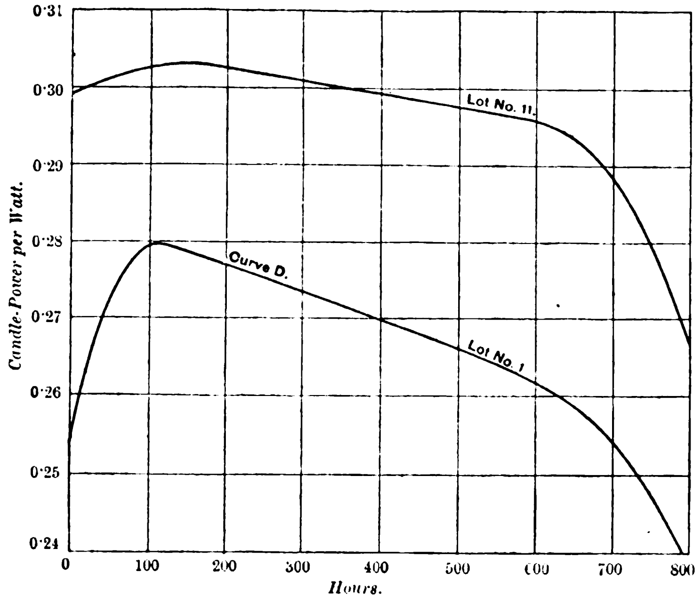
Curve "B," per cent. of Initial Candle-Power.

The total range in candle-power from beginning to end, is 22 per cent. for Lot I., and 14·5 per cent. for Lot II.



Curve "C," Watts per Candle-Power.

Curve C shows a marked increase in efficiency for Lot I. on the start, falling back to the initial value only after 600 hours. Lot II.



Curve "D," Candle-Power per Watt.

improves in efficiency also on the start, though to a smaller extent, and continues at a practically uniform figure for 600 hours. The decrease in efficiency of each lot after 600 hours is much less rapid than usual. Curve D shows the candle-power per watt.

With the tests as a basis, computations were made as to the economy of the lamps. For this purpose the cost of the lamp was assumed at 20 cents and that of the kilowatt-hour at 20 cents. Under the conditions assumed, the lamps in Lot I. show a minimum average cost of the light produced by them, under the conditions assumed, at about 450 hours. Lot II. shows a minimum, under the same conditions, at 650 hours. The difference in cost of light produced by the two lots, at the minimum point for each lot, is about 7 per cent. in favour of Lot II. The range in candle-power of Lot I., up to 450 hours, is about 15 per cent., while that of Lot II. is only 6½ per cent. up to 650 hours. Lot II. is better than Lot I. on this account also, as uniformity of candle-power is desirable, other things being equal.

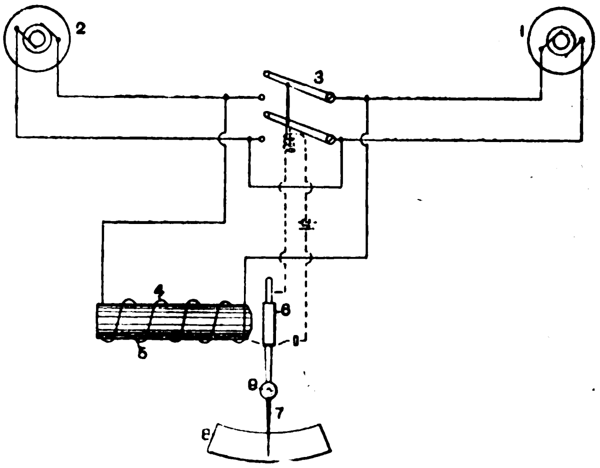
The prices used were chosen because they fairly represent lamp cost, and cost of energy as supplied by central lighting stations in this country to-day. Higher prices for lamps, or a lower price per kilowatt-hour, will bring the "smashing point" for either lot later than the times named, though no change in the relative value of the two lots will follow, if compared under like conditions.

For isolated plant work, the net cost of energy is considerably decreased, and may be taken at less than 10 cents per kilowatt-hour—in some cases as low as 6 cents. For such work, the computed cost will show a minimum at or beyond 800 hours. The "smashing point" will in some cases not be the question of cost of light produced, but the decrease in candle-power of the lamps being reached when the light produced by the lamps is no longer satisfactory. No lamp of either lot showed any serious blackening, and the majority of the lamps were scarcely blackened at all.

Taking economy, maintenance of candle-power and freedom from blackening into account, the results obtained from these lamps according to Prof. Thomas are much superior to any heretofore published.

THE MERSHON SYNCHRONISM INDICATOR.*

In order to connect alternating machines in parallel to the same circuit they must be at the same phase, or in synchronism, and in order to determine this point various devices have been employed. Thus in some cases an acoustic indicator is used, while in others an incandescent lamp placed across the terminals of the machines to be connected is observed, and when at its greatest brilliancy the switch is thrown. The point of greatest brilliancy in an incandescent lamp is somewhat difficult to determine, except by experience, and with the object of supplying a device which can be read off with accuracy by the ordinary station attendant, Mr. Ralph D. Mershon, of the Westinghouse Company, has devised the arrangement shown in the accompanying engraving.



Mershon Synchroniser.

This indicator has the advantage also of being equally well adapted for alternating circuits of high and low frequency, the acoustic indicator being unavailable for frequencies below a certain limit.

The indicator consists of a coil 4 connected to the machines, as shown, and acting upon an armature which carries a pointer passing over a scale. The armature may be either of iron or consist of a closed coil or a disc of non-magnetic material, in the latter case being acted on inductively. Assuming the coil 4 to be so connected in circuit that the electromotive forces therein will be in opposition when the machines are in the proper relation for closing the switch 3, the armature 6 will, in the absence of such relation, be moved either toward or away from the coil 4 and its core 5, the

* From the *Electrical Engineer* of New York.

Digitized by Google

direction of such movement being dependent upon whether the armature be of magnetisable or non-magnetisable metal. As the two machines approach the same speed, and the electromotive forces come more nearly into opposition, the armature will tend to return to its original or zero position until the relation of the machines is such that they may properly be connected in circuit, when the armature and its pointer will be in approximately the position shown in Fig. 1.

If, on the other hand, coil 4 be so connected in circuit that there shall be a coincidence of the electromotive forces therein when the machines are in the proper relation for connecting them in circuit, the operation of the device will be the reverse of that above described—that is to say, if the armature be of magnetisable material its extreme left-hand position will indicate the time for closing the switch, and if of non-magnetisable material its extreme right-hand position will give the proper indication, the vertical or zero position, indicating the absence of the desired relation of the two machines.

Mr. Mershon prefers to so connect the coil in circuit that there shall be an opposition of electromotive forces therein at the proper time for throwing the switch and to employ a non-magnetic armature; but the other connection and variety of armature described are entirely practical and may be employed. It is obvious that the armature or its pointer may also serve, if desired, to close a circuit, which shall operate to effect the closing of the switch automatically.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

New York, *August 23, 1895.*

Extensive Consolidation.—An arrangement of considerable importance has been consummated between the three largest traction companies in Philadelphia, the basis of the arrangement being broadly as follows: A new corporation has been formed known as the Union Traction Company, which concern has purchased practically all of the shares of the Electric and People's Traction Companies, and has acquired, by lease and otherwise, the control of all the lines forming the system of the Philadelphia Traction Company. The new Company is capitalised at $30,000,000, about $24,000,000 of which will be absorbed in obtaining the control of the above-named Companies and $4,500,000 devoted to extensions and improvements now in hand and contemplated, leaving a margin of about $1,500,000. The deal has been approved by the directorates of all the Companies concerned, and a majority of the stockholders have filed their assents.

Long-Distance Power Transmission.—An unusually ambitious undertaking is in progress in the State of California. The scheme contemplates the transmission of 1,000 H.P. or more from a point on the San Joaquin river to the city of Fresno, Cal., a distance of 35 miles. The power station will be located at the foot of a mountain on the riverside, and will contain special water-wheels designed for abnormal heads and three three-phased alternating-current generators of 340 kilowatts each. On the mountain top, 1,500 feet above the station, a reservoir has been constructed which will hold enough water for several days' run in case of trouble with the prime water supply. A canal will bring the water from a point about seven miles up the river to the reservoir, and welded steel pipes will serve to convey the water from the reservoir down to the water-wheels in the station. The E.M.F. on the line will be 11,000 volts, which will be reduced by step-down transformers at a sub-station in the city of Fresno, from which current will be supplied for incandescent lights and stationary motors directly from the secondary mains. Rotary transforming sets will be located in the sub-station for the purpose of converting the alternating current into direct current for operating arc lamps and the street railway system of the city, the latter requiring about 300 H.P.

MAGNETIC UNITS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: The reluctance to extend to magnetic units the same sort of treatment as has proved successful with electric units is somewhat surprising. There are some who hold that such a statement as that $\mathsf{N} = 10$ is sufficient, but I hope that Prof. Ewing will, after consideration, dissociate himself from these, inasmuch as it could only be accurate if N were a pure number. As it stands it tells us nothing, any more than the statement that "the depth of the sea at a certain bar is 60" has any meaning unless we are told whether feet or fathoms are meant. It is true that a unit equal to 10^8 C.G.S. is large, but a unit of 1 C.G.S. is just as much too small, for dynamo purposes.

Those who hold that no simple multiples are of any use ought to speak of an event as going to occur in 15,834,000 seconds, instead of in three weeks; and they should express the distance from here to York in feet or inches.

There are certainly two quantities on which agreement is needed. If "lines" and "ampere-turns" respectively are held sufficient by a decided majority of those concerned, very good —let them be agreed upon; but it cannot be good for everyone to be devising a unit of his own. (And, by the way, I have nowhere urged people to make the henry of any size other than the secohm, as Prof. Ewing seems to imagine.)

The idea underlying my draft suggestions was mainly that it was well to consider the entire aspect of the question before finally deciding on the units for even these two essential quantities.—Yours, &c., Oliver J. Lodge.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Dr. Lodge's suggestions chiefly refer to three units for quantities intimately related to H, B and L.

First, as regards H. Since $\mathsf{B} = \mu\,\mathsf{H}$, the magnetism induced in a magnetic circuit easily follows from H. Considering an anchor ring of iron with n turns of wire round it carrying a current of A amperes, and supposing l is the circumferential length of the core,

then $$\mathsf{H} = \frac{4\pi}{10}\,\frac{n\,\mathrm{A}}{l}.$$

A being in amperes, and l in centimetres, $\frac{4\pi}{10} n\,\mathrm{A}$ is called the magnetomotive force = M.M.F., and total lines = $\mathsf{B} \times$ area $= \mu\,\mathsf{H} \times \text{area} = \dfrac{\text{M.M.F.}}{\dfrac{l}{\mu\,\text{area}}}$, and $\dfrac{l}{\mu\,\text{area}}$ is called the magnetic resistance.

Dr. Lodge suggests a name for the unit of M.M.F. But really there is *one in use*—viz., the ampere-turn, and M.M.F. $= \frac{4\pi}{10} \times$ ampere-turns.

The constant is of no importance to practical men, they are so used to them in their formulæ. The $\frac{4\pi}{10}$ cannot be got rid of. Mr. Heaviside proposes to alter the size of the ampere, so as to get rid of it in this equation (and this would involve changing either the ohm or the volt to correspond). Is it ever likely this suggestion will be adopted?

Then, as regards B, Dr. Lodge proposes a name not for B exactly, but for $\mathsf{B} \times \text{area} = \mathsf{N}$ = total number of lines. In this I quite agree, but the point is that with few exceptions everyone already uses the word *line* for this purpose, sometimes with the prefix "magnetic," sometimes with the affix "of force," and sometimes alone; but all use the word line, and, strange to say, nearly all people, practical and theoretical, use the C.G.S. unit for N, although when the density of lines is considered some use N per square centimetre (or B), others N per square inch, and others use the Kapp unit. Now it seems to me a pity to try to substitute any word for *line*. As regards the unit corresponding with the volt and ampere—*i.e.*, 10^8 lines, opinions differ as to whether the unit is wanted or not. Whenever I have had occasion to use it I have employed the word

Digitized by Google

volt-line for the purpose. But I think the unit can very well be done without for the present.

Then as regards L; this only becomes of practical interest when iron is used, and then it is such a variable quantity that only by a stretch of the imagination can it be said to exist. Since L is only of importance as a means of calculating the number of lines N from the current strength, it is best when L is variable to calculate N by the ordinary method of the magnetic circuit, and to leave out L altogether.

Then as regards units generally, I disagree with the idea of naming units after celebrated men. First, one has to find a unit which is wanted, then to make successive international congresses agree to sink their national prejudices, and, finally, to make "practicians" adopt the name. Which task is most difficult is hard to say, but, having done all this, people have yet to be taught the meaning of the name. My own idea is that units should grow up themselves as they are wanted, in the manner exemplified by the word "ampere-turn." This has simply been compounded of the words which in the shortest way explain its meaning. It has not been authorised by any congress. It has simply grown up in a natural way, and in spite of congresses it will last. Another word like it is secohm. This word has been smashed, pulverised and destroyed by two or three scientific gatherings—the B.A., and the French, and the American Congresses. Yet where is the word "quadrant," and where is the word "henry?" No one seems quite certain what henry means, but the word secohm explains itself; and, in spite of the word secohm being thrown over three times, it is yet to be discussed at the next B.A. meeting. The reason is that the word is founded on a rational system, whereas henry has nothing but sentiment to recommend it. Though the term volt-line for 10^8 lines has, as far as I know, never been used, I cannot help thinking it a much better word than "weber," or "gauss," or any such name having no apparent connection with what it is supposed to represent.

If a unit is very badly wanted, of course people may agree on a name like ohm, ampere, or volt. But as a rule these units are *not* badly wanted, and it is best to let the names grow up by themselves in the way suggested. A "volt-line" is such that when a circuit loses lines of force at the rate of one "volt-line" per second, the E.M.F. generated in the circuit is one volt. Hence the name. One can easily imagine names being given in this way. There is no national jealousy to delay the adoption of a name founded in this manner, for it is chosen for convenience and explicitness merely.—Yours, &c.,

W. E. SUMPNER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Prof. Silvanus Thompson's letter in your issue of August 23rd leaves so little to be desired as a clear statement of the magnetic quantities with which electricians have to deal, and of the logical sequence in which they occur in matters of design, that, with one exception, it may, I think, be taken to express the feelings of those who have to practically use measurements in matters of construction. I refer to the omission of a unit coefficient of self-induction. It is true that from certain points of view it is an additional and unnecessary unit, but so saturated is the existing writing on electro-dynamics with the ideas and formulæ which embody its use that it really becomes a necessity.

Whether the C.G.S. system is the best or not is, I feel, a question which it is too late to discuss; it at least has the advantage of consistency and simplicity, and taking as it does three fundamental arbitrary quantities and choosing water for mechanical and thermal quantities and the ether or air in electro-magnetic quantities as the standard substances, the memory is burdened with few constants.

But when we come to the so-called practical system, this simplicity is at once lost. It is true that so long as we are dealing with some beaten path of design it is possible to keep straight, but I have found that in any new lines of design or investigation involving mechanical, electrical, and, perhaps, thermo-dynamical quantities, the practical units lead to hopeless muddle. The purpose, as I understand it, of the practical units is to provide that all ordinary measurements shall fall between the figures 1 and 1,000. If it effected this it might be an excuse; as it does not, I fail to see where the advantage comes in. Most designers use a slide rule, and in order to keep the decimal place (which is far more troublesome than 4π) under proper control many I know do as I do, and write every number down as an integer (under ten), with, say, two places of decimals, followed by 10^x, x being + or −. So that the only difference between the practical and absolute unit is the value of x.

But the objection to the practical unit is that you have to remember, if you can, or, if you cannot, use a table to find how many absolute units there are in a practical unit. We might as well have stuck to our pounds, and feet and bushels, and gills and perches, and the rest of them.

In a word, I regard all these practical units as an unmitigated nuisance, and therefore view the proposed augmentation of their number with alarm.

But, in addition, in order to avoid 4π in the expression for the line integral of magnetic force, we are threatened with another complication in the adoption of a system in which air or ether is not to be the standard substance. It appears to me it would be equally logical to have a special system of units for expressing the circumferences and areas of circles and volumes of spheres, in order to avoid π appearing in these space quantities.

Engineers find no difficulty in this case, nor will they in the case of the magnetic force if only they are left alone. Give names if you will to the absolute units, for by so doing statement of quantity is simplified, and let the units be of those quantities named by Prof. Thompson, with the addition I before mentioned; but do not let us be burdened with fresh arbitrary multiples under the name of practical units.—Yours, &c.,

LLEWELYN B. ATKINSON.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is without doubt desirable that the relations between the magnetic units should be expressed in simple terms, avoiding the ambiguity which often exists at the present moment. If the Electrical Standards Committee of the British Association succeed in doing this the Ipswich meeting will have done good work.

Without presuming to discuss the theoretical difficulties in the way, perhaps I may be permitted to state how the matter strikes me as a practical man who has had to design many machines. The first quantity to be determined in designing dynamos is evidently the total quantity of magnetism in the induced circuit; its name is of little importance, much less that of the unit. I always think of this quantity as *lines*, and, following Prof. Silvanus P. Thompson, denote it by the symbol N; it has different values for different parts of the magnetic circuit, of course. The next quantity is found by dividing N by the effective area expressed in square inches or centimetres. This I denote by the symbol B″ or B, according to the unit of area. Its name is of no importance. I think of it as a density. Finally, the magnetomotive force required to produce N must be determined. This quantity is most readily and obviously, may I say, expressed in ampere-turns, because both the numbers of amperes and of turns of wire are so easily measured by shop methods. The relation between the ampere-turns per inch or per centimetre of circuit for a given value of B″ or B is taken from curves easily calculated within the required limits of accuracy. There is no substantial difficulty about the matter, except such as may lie in the uncertainty of the iron data.

If by changing the units of these quantities it were possible to make the reluctance vary as the magnetomotive divided by the total lines—*i.e.*, to follow a simple law like that connecting electromotive force, current and resistance—it would be worth while to make the change. But it appears to me that as the permeability of iron does not follow a straight line law, no equation can be of use in practice, except in conjunction with tables showing the variations of the permeability. In fact, it is necessary to resort to the usual curves of magnetism. In practice, I arrange things so that B″ is plotted in relation to

Digitized by Google

ampere-turns per lineal inch (*see* p. 35, "Electric Motive Power").

The $4\pi/10$ difficulty is really of little importance in designing work, as it is easily included in the calculations for determining the tables or curves which are now used by every man who has to get his living at this branch of engineering.

In designing alternators the matter is more complicated owing to inductance. Yet it is possible to design very good alternators without a knowledge of the exact value of the *henry*, and I think that many designers build their machine first and determine this quantity afterwards. The unit of inductance should be defined in a simple manner which will lend itself to practice.—Yours, &c., ALBION T. SNELL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Like the bulk of your correspondents in last week's issue, I have not experienced any need for new names for magnetic units. To me $\mathsf{N} = 10,000,000$ is as convenient an expression as $\mathsf{N} = 10$ megalines. If only the C.G.S. system is taken for granted, nothing more is required than the number expressing the quantity of the thing in question. For example, when in steam engineering the question is asked, "What is the boiler pressure?" would it not be simpler to say 100 than to say 100lb. per square inch? Yet the only reason for adding "pounds per square inch" is the fact that in other countries "kilogrammes per square centimetre," for instance, are in use. If a coinage system were universal among civilised nations, and that coinage system were a decimal one, what need would there be for anything more than a plain number with a decimal point to express a given value? And if any name were given, would not this inevitably get dropped in time as a useless encumbrance? Engineers have been content to use the definition "pounds per square inch" instead of giving a name to a unit which would need defining, but if steam pressure was universally measured in pounds per square inch, or kilogrammes per square centimetre, it would be superfluous to write or speak either of these expressions. Now, I take it that, except for a few gentlemen, mostly in this country, who find it too much trouble to remember the multiplier 2·54, the C.G.S. system is universally adopted in electrical calculations. My view of the matter, then, is that every effort should be used by those engaged in electrical work to ensure that the unit for each thing to be measured shall have but one definition; then the only thing to be remembered would be the fundamental and unalterable physical relations between the things dealt with.

Supposing it is asked, "What is the unit of self-induction?" the reply sought for is invariably not the *name* of the unit, but the definition of it. If, then, there is but one definition, there is no need for a name.

I agree with Prof. S. P. Thompson that there should be no "academic fatuities" as to whether B stands for flux in air or in iron. The total flux is the same through all parts of a magnetic circuit, and its inductive effect when changing is the same whether it exists in air or in iron, and the fact that in air and most other substances $\mathsf{B} = \mathsf{H}$ should lead to no confusion, but rather towards clear relationship and simplicity.—Yours, &c., W. B. SAYERS.

Glenwood, Bearsden.

ELECTRICALLY DRIVEN ROAD CARRIAGES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On page 568 of the current issue you make the following editorial comment: "And yet, with the practical possibility of accumulator tramway traction still an open question, there are individuals who affect to believe in electric omnibuses." Perhaps you will have the kindness to spare me a few lines of your valuable space to reply somewhat briefly to the innuendo conveyed therein. As I had the privilege of running over 2,000 miles in the Ward Company's 1888 accumulator omnibus, it is patent to my mind that secondary cells, if no better now than they were then, can be effectively applied to this kind of traction. I have elsewhere endeavoured to combat the erroneous impressions that have been formed by many, lacking in practical experience, of what was done and can be done in this respect. It may be interesting to point out that in this country, on the Continent, and in America there are a large number of experimental vehicles of the self-contained type that have given good results, and the question was gone into by me at length in some articles I wrote for *Industries and Iron* when editor-in-chief of that paper, about 18 months ago. For example, the carriages of Arnold, Cumming, Ward, Bersey, Garrard, Pouchain, Morris and Salom, Jeantaud, Morrison, McDonald, and others have proved that, given financial support, an urban service could be established that would prove a satisfactory investment. We have three companies in this country engaged in the work, and when their preliminary investigations are completed, some tangible results may be expected. It is impossible to deal properly with the *pros* and *cons* of a question like this in the space allotted to a letter, and I must leave the full discussion for a more opportune occasion. —Yours, &c., CHARLES H. YEAMAN.

134, Calabria-road, Highbury, N.,
September 2, 1895.

BRITISH *v.* CONTINENTAL TELEPHONY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: There is a point raised by Mr. Bennett in your issue of the 30th ult. which is worthy of attention from the National Telephone Company—I mean provision for sickness and old age of its staff.

There have been various attempts, both by the public and former employés, to stigmatise this Company—by the former, owing to ignorance; by the latter, owing to malice—and we have seen how futile they have been when closely examined.

There is here, however, a genuine weak point of which I hope the Company will speedily take note. It has at the present moment a staff as loyal and devoted as can be found in the service of any public company in the country, and, considering every responsible company makes some provision for the future of its trustworthy servants, it is clearly a piece of policy, apart from the question of duty, for this Company to do the same.

The Company may plead as an excuse for this remissness the doubt and uncertainty that hang about the Government policy with regard to it; but in the meantime, while it benefits largely from this policy, the staff is being neglected.

The present General Manager has done much to deserve the deepest thanks of almost all grades of the service. He has relieved the pressure of petty local tyranny, and established a feeling of security within the limits of justice; and now we feel this point will not escape his administrative tact.—Yours, &c., AMICUS.

September 3, 1895.

LEGAL INTELLIGENCE.

Pembroke Town Commissioners v. Dublin Southern District Tramways Company (Limited).

On Tuesday an application was made to Mr. Justice Murphy (sitting as Vacation Judge) at Dublin by Mr. Piers White, Q.C., on behalf of the plaintiffs, for an injunction to restrain the defendant Company from breaking up or excavating the roadway between the tram rails and the footpath in the township of Pembroke. Counsel explained that on the previous day the defendants, in connection with the laying down of their new electric tramway, commenced to break up the road close to the boundary of the Pembroke and Blackrock townships in the face of the protests of the plaintiffs, in contravention of an understanding arrived at when the defendants were seeking powers in Parliament for the purpose of using electricity on their tramway, and in contravention of Section 14 of their Act, which gave them power to work the tramway by overhead wires only, whereas, as now alleged, they were about to sink cables in the roadway for the purpose of conducting the electric current by underground conductors. At the request of the defendant Company the application was allowed to stand over for a week, on the understanding that the work objected to would not be proceeded with in the meantime.

Quayle v. Caustic Soda and Chlorine Syndicate (Limited).

In this action, on Wednesday last week, Mr. Justice Mathew made an Order authorising the Receiver and Manager to borrow money to pay out a distress and keep the defendant concern in a fit condition.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

TENDERS INVITED.—The Corporation of Sunderland invite tenders for (*a*) high-tension and low-tension concentric cables, (*b*) cast-iron pipes and box frames and covers, (*c*) stoneware casing, boxes, and bell-mouth protectors; (*d*) high-tension transformers for alternating current, and (*e*) meters for alternating current. Specifications may be obtained from the Borough Electrical Engineer (Mr. C. S. Vesey Brown), Electricity Supply Station, Sunderland. Tenders must be in by 6:30 p.m. on Friday, September 13th. Some further particulars appear in our advertisement columns.

——— The Vestry of Shoreditch invite tenders for insulated electric mains, conduits, and drawing-in boxes, to be laid in the parish. Specifications can be obtained of the Vestry's consulting engineers, Messrs. Kincaid, Waller and Manville, 29, Great George-street, Westminster, S.W. Tenders, addressed to H. Mansfield Robinson, Vestry Clerk, Town Hall, Old-street, E.C., must be sent in by four o'clock on Tuesday, 17th inst. Further particulars will be found in our advertisement columns.

——— The Gravesend Town Council invite tenders for supplying and fixing a telephone and connections between the Sanatorium and the office of the sanitary inspector and the police station. Tenders to Mr. Hatten, Town Clerk, Gravesend, by 20th inst.

——— The Dundalk Town Commissioners invite tenders for the erection and maintenance of the necessary plant for lighting the town by electricity from July 1, 1896. Tenders to Mr. Ferrar, Town Clerk, Dundalk, by October 7th.

——— The St. Giles and Bloomsbury Guardians invite tenders for wiring and fitting up the board room and offices for the electric light. Tenders to Mr. J. Appleton, 57, Broad-street, W.C., by 10th inst.

——— The Manchester Town Council invite tenders for the laying of a system of underground telephone pipes, with inspection pits, service boxes, &c., in certain streets of the city. Tenders to Paving, Sewering and Highways Committee, Town Hall, Manchester, by 17th instant.

——— The Asylums Committee of the London County Council invite tenders for the erection of fire alarm and telephone systems at their asylums at Banstead, Surrey, and Colney Hatch, London, N. Particulars from Mr. R. W. Partridge, Clerk of the Asylums Committee, and tenders must be sent in to 21, Whitehall-place, London, S.W., by 12 o'clock on the 30th instant.

——— The French Post and Telegraph Department invite tenders for the supply of a quantity of iron tubes for pneumatic telegraph lines. Tenders to the Direction Générale des Postes et des Telegraphes, 103, Rue de Grenelle, Paris, by the 16th instant.

——— Further particulars are to hand respecting the establishment of electric tramways in Braila, Roumania. They are to be worked on the accumulator system, the cars to be provided with outside seats, and the speed to range from 9 to 24 miles per hour. The concession is for 35 years, at the termination of which the cars, plant and rolling stock are to become the property of the town without compensation. There are five routes in the concession, for which offers are to be sent in to the Maire by October 2nd.

——— The Queenstown Town Commissioners require tenders for the erection of works and the necessary plant for generating electric current for the public and private lighting of the town. Tenders to be in by September 26th.

——— The Staffordshire County Infirmary Committee require tenders for wiring and fitting up the Infirmary for the electric light. Tenders must be in by noon on Saturday, September 14th.

——— The Baths Committee of the Oldham Corporation invite tenders for supplying and fixing wires, fittings, &c., for lighting a portion of the Central Baths, Oldham, by electricity. Tenders by noon on September 11th.

TENDERS ACCEPTED.—The Parish Council of Thorne (Yorks.) have accepted the tenders of the Thorne Gas Company for lighting by gas that part of the town which is included in the lighting area. The Town and Village Electric Lighting Company was the only other tenderer, but no price was given in their tender. The Gas Company receive 26s. per lamp for 71 lamps for a period of eight months from September 1st to April 30th.

——— The Cheltenham Town Council have accepted the tender of Messrs. G. E. Belliss and Co. (Limited), of Ledsam-street Works, Birmingham, for supplying an additional steam engine for their electricity works for £729. 17s.

——— The Electric Light Committee of the Belfast Corporation have accepted the following tenders: Doulton and Co., for insulators; Messrs. J. Shaw and Co., for ironwork; the Callender Company, for cable; the British Insulated Wire Company, for copper strip; Messrs. R. Paterson and Son, for inspection plugs; and Messrs. Wormald and Co., for covering exhaust pipes.

——— The Watch Committee of the Portsmouth Town Council have decided to accept the tender of Messrs. Newton and Co. for wiring and fitting up the Buckland, Southsea, Portsmouth and Portsea police stations for the electric light.

TENDERS RECEIVED.—The Islington Vestry (London, N.) received 32 tenders for the wiring of the Vestry Hall and municipal offices for the electric light, the highest of which was £756. The lowest and *accepted* tender was that of Mr. Sidney Newton, 15A, Baker-street, London, N., for the sum of £215.

——— The following tenders have been received for supplying the necessary plant, &c., for the electric lighting of the Naval Station, Garden Island, Sydney, N.S.W.:—

Kingsbury (H. H.) and Co., Sydney	£6,975
Gibson, Battle and Co. (Sydney Branch)	6,433
Crompton Electric Supply Company of Australia	5,800
Siemens Bros. and Co. (Sydney Branch)	5,189
Standard Electric Company (No. 1 scheme)	4,935
Ditto (No. 2 scheme)	4,683
Ditto (No. 3 scheme)	4,564
Ditto (No. 4 scheme)	4,351
Morris Bros., Sydney	4,675
R. W. Thomson, Adelaide	4,601
Edge and Edge, Melbourne	4,386
Brush Electrical Engineering Company	4,250

APPOINTMENTS VACANT.—The Electric Light Committee of the Borough of Kingston-upon-Hull are prepared to receive applications for the position of resident electrical engineer at their electricity supply station. Salary £250 per annum, and applications must be sent in to the Town Clerk (Mr. R. Hill Dawe), Town Hall, Hull, by noon on the 19th instant.

——— The Technical Instruction Committee of the Borough of Lowestoft require a Technical and Science Master. Salary £160 per annum. Applications to the Town Clerk, Town Hall, Lowestoft, by the 19th inst.

BUSINESS CHANGES.—Messrs. J. Lomax Kendal and Co. inform us that they have taken over the electrical engineering business lately carried on by Messrs. Lowcock, Hill and Co. (Limited), at St. James's-square, Manchester. Messrs. Kendal and Co. have decided to retain the staff of the late firm. The Company also forward us a lengthy list of installations carried out successfully.

LIQUIDATIONS.—A meeting is to be held at 68, Coleman-street, London, E.C., on October 3rd, at 12 o'clock, to receive an account of the winding-up of the Submarine Mining and Torpedo Explosives Company (Limited).

——— Amongst the creditors in the failure of Dalziel's News Agency of America (Limited) are:—

Dalziel's London Agency	£12,319	2	3
H. F. Jackson, London	125	0	0
Cie. Française du Télégraphe de Paris à New York	1,100	0	0
Postal Telegraph Company, New York	650	0	0
Western Union Telegraph Company, New York	75	0	0

——— In the matter of a Registered Deed by John Ball, trading as Ball and Co., electricians, St. Nicholas-street, Leicester, the following are some of the principal creditors under the failure:—

Bonella (D. H.) and Son, London	£19	0	0
General Electric Company	36	0	0
Showell (E.) and Sons, Birmingham	10	0	0
J. W. Heawood, Leicester	15	0	0
J. E. Lester, Leicester	14	0	0
Greatorex (S., jun.) and Bro. (Limited), Manchester	12	0	0

EXTENSION OF PREMISES.—Messrs. Marryat, Lillywhite and Co., in order to meet a gratifying growth of business, have taken additional premises at 28, Hatton Garden, where, in addition to offices, showrooms for machinery and fittings will be added.

TUDOR ACCUMULATORS.—The sole manufacturer in the United Kingdom of these accumulators is Mr. A. B. Pescatore, of 5, Cross-street, Manchester, who sends us a price list, just issued, containing, in addition to prices, particulars concerning the batteries. Works

Digitized by Google

have been established at Dukinfield, near Manchester, for the manufacture of the batteries, of which some 5,000 are working in different parts of the world at the present time. It is claimed that the cells can be discharged daily in 1 hour and recharged in 2½ hours without damage to the plates. A guarantee is given. The maintenance of the batteries is contracted for at the rate of from 3½ to 6 per cent. of the list prices. A supplementary price list will shortly be issued of portable cells and of a new and improved type of automatic regulating switch.

THE "WEINERT" ARC LAMP.—Messrs. Wilhelm and Co., of the Wool Exchange, Coleman-street, London, E.C., have been appointed sole agents for the United Kingdom for the arc lamps, arc lamp accessories, &c., manufactured by Mr. K. Weinert, of Berlin. Fig. 1 shows the differential type of lamp, which, however, by the necessary alteration of the coils, can be used also as a shunt

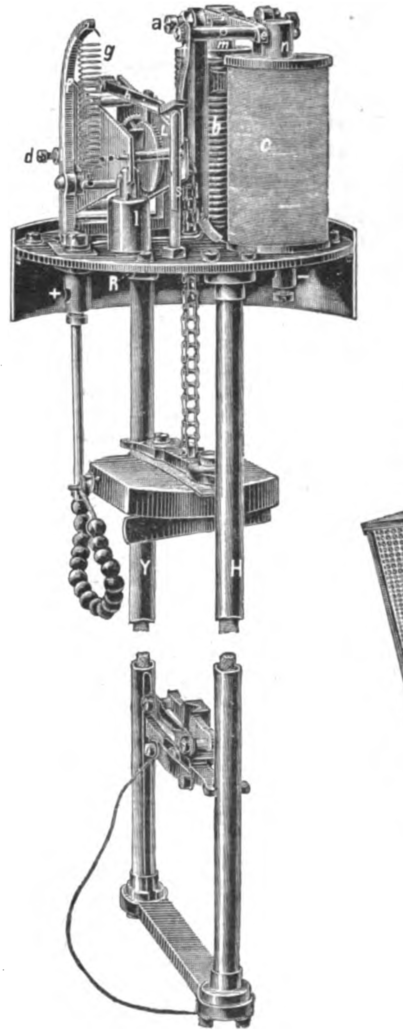

FIG. 1.

FIG. 2.

or series-coil lamp, for continuous or alternating current. The general principle of this lamp is not unlike that of the old Crompton lamp. Fig. 2 shows an arc-lamp lantern, the panes being of crystal glass, one side of which is formed prismatically, ensuring the better distribution of light. Some of the fittings illustrated in the catalogue, from which these particulars are obtained, are of very ornamental design.

"THE ENGINEERING MAGAZINE."—The September issue of this magazine is now ready, and in the variety of the subjects dealt with and in its illustrations fully maintains its high standard of excellence. The contents of the present number (No. 6, Vol. IX.) include: "The Business Situation in Review, and Factors in the Recent Improvement," by Newton Sharp; "The Emancipation of Labour by Machinery," by A. E. Outerbridge, jun.; "Natural Science Training for Engineers," by N. S. Shaler; "Labour Legislation in the United States," by George Kirby Holmes; "The Modern Problem of Grade Crossings," by William O. Webber; "The Earliest Transatlantic Steamships," by S. W. Stanton; "Surveying and Mapping a City," by C. H. Rice; "The Revolution in Steel Making," by William Metcalf; "Ontario Drain Tunnel and Electric Plant," by C. R. McKay; "The Architecture of Modern Hospitals," by E. C. Gardner. The usual exhaustive Review of the World's Industrial Press is also given. All the back numbers may be obtained at the offices, 1, 2 and 3, Salisbury-court, Fleet-street, London. A complete index to the main articles in the magazine from the commencement in April, 1891, will be ready in a few days, and will be forwarded post free on request.

CATALOGUES.—Mr. L. C. H. Mensing, of Worship-street, London, E.C., has just issued a catalogue of electrical engineering plant, including dynamos, motors, and arc lamps. Illustrations are given of Mensing machines, and a full text description, accompanied by sectional drawings, is included in the catalogue, which consists of 70 large quarto pages.

——— We have received from Mr. R. W. Paul, of Hatton-garden, the advance sheets of a very complete catalogue of electrical instruments. Amongst other things the large variety of resistances made by Mr. Paul is noticeable. These resistances include ordinary rheostats, Varley carbon rheostats, and liquid rheostats, with zinc electrodes immersed in zinc sulphate solution. Mr. Paul has also brought out some handy forms of lecture-room galvanometers, with 10in. pointers and boldly-divided scales. Ordinary and extra-ordinary galvanometers, celluloid scales, semi-transparent scales, portable testing sets, &c., will be found described within the covers of this catalogue, the only drawback to which is the embarrassing choice it offers to intending purchasers with limited funds.

OUTING.—The employés of Messrs. Marryat, Lillywhite and Co. held their annual outing on the 24th ult. on the Thames, where a steam launch conveyed the party from Kingston to Windsor and back, dinner, &c., being provided at Chertsey. The party numbered over 30, and a pleasant day was spent.

ABERDEEN.—The electric light is making steady progress in this city. The accounts of the electricity department of the Corporation show a small loss for the past year. Numerous additional applications for current, including several from medical men in Union-street and Bridge-street, have recently been received. New mains are being laid in Bridge-street, and a considerable demand for current is anticipated from the owners of large warehouses in that district.

ALDERLEY EDGE (CHESHIRE).—At the last meeting of the District Council a letter was read from Mr. S. V. Clirehugh, electrical engineer, of Manchester, offering to purchase the Council's Provisional Order, and stating that he was authorised by his clients to offer in return for the Order to pay the costs incurred in obtaining it, and that his clients were prepared to supply the Council with electric current for lighting purposes at 32s. 6d. per lamp per annum. The present gas lamps cost 35s. each. The letter has been referred to the Finance Committee for consideration.

THE ANGLO-FRENCH TELEPHONE.—In the House of Commons Mr. Hanbury said that the Postmaster-General was not prepared to grant statistics relating to the Paris-London telephone, as he was of opinion that the telegraph business of the State must be dealt with as a whole; nor could the Postmaster-General reduce the cost of conversation between France and England from 8s. to 2s. 6d. for three minutes, as such a reduction would necessarily lead to a loss of revenue from the telephone, which, during many hours of the day, is fully occupied.

BANGOR.—At the last meeting the City Council discussed the report of the Electric Lighting Committee, which recommended that the Council apply for a Provisional Order and that the Committee be empowered to carry out a scheme for the electric lighting of the city at once, so that current may be available by the end of 1896. The Committee further recommended that a field near the Police Station be purchased from Lord Penrhyn for £400 to serve as a site for a generating station. The recommendations were, after a brief discussion, adopted.

BERLIN INDUSTRIAL EXHIBITION.—In our issue of August 23rd we gave some particulars of this Exhibition, which is to be held in Berlin next year. The prime object of the promoters was to demonstrate the progress and expansion of the various industries of the city of Berlin since its recognition as the imperial capital in 1871; but it is stated that the Exhibition has been received with such favour that it has already acquired the dimensions of a national enterprise of the first rank. A guarantee fund of more than 5,000,000 marks (£200,000) has been subscribed, and 5,000 intending exhibitors have already applied for space. The main building has a capacity of 60,000 square meters, but around this there are about 50 smaller buildings which will be utilised for special exhibits. The exhibits will be divided into 24 groups, and sections will be devoted to applied electricity, machine construction, building and engineering, shipbuilding and transport, and to textile, chemical, metal and india-rubber industries. The Fishery and Colonial Exhibitions will be amalgamated with the Industrial Exhibition, and will embrace the industries of the German Empire within their scope. It is also stated that a large number of electric and elevated railways are to be laid down in order to facilitate passenger and other traffic between the city and the exhibition building, which will be erected on the Treptow Park.

Digitized by Google

BIRKDALE (NEAR SOUTHPORT).—At the last meeting of the District Council a request from a Birkdale resident gave some trouble. An application was made for the consent of the Council to allow Mr. Buckley, who resides within the district, in case the Southport Corporation bring their electric light mains to the boundary, to put down a small private cable to his house and take current from the Southport Corporation's mains, the applicant undertaking to remove his cable when the District Council adopt the electric light. The consent of the Council involved important considerations, one being the rebate on the gas supply as arranged with the local gas company. Nothing definite was, however, decided.

BLACKPOOL.—At the meeting of the Blackpool Town Council on Tuesday last the recommendations of the Electric Lighting and Tramways Committee, that two complete sets of electric lighting plant, having a combined capacity of 600 kilowatts, should be immediately laid down; that Mr. Robert Hammond should prepare the specifications, and that the Finance Committee should borrow £30,000, met with considerable opposition, which finally won the day. Mr. Councillor Pearson, Chairman of the Committee, said that, with regard to the financial question, they estimated last year that their loss would have been £500, but after charging everything they possibly could to revenue account, and putting £716 to the sinking fund, they had only a net loss of £277. The total cost of the unit, he said, came out at 3·78d. At the present moment the profits were going up by leaps and bounds. Comparing the cost of the arc lamps at Blackpool with those of other towns, he stated that, including the sinking fund, their arcs cost them £22. 10s. per annum, while at Eastbourne the figures were £30, Hastings £25, Chelmsford £28, and Brighton £30. As an instance of the economical manner in which the capital had been expended at Blackpool, he pointed out that the expenditure at that town was £52,000, or £78 per kilowatt; the corresponding figure at Brighton was £131. Each lamp installed, according to the capital account, cost £2. 5s. 3d., and at Brighton £3. 2s. 5d. Mr. Councillor Ward moved the following amendment to the Committee's recommendations: "That the Corporation do not sanction any extension for electric light plant within twelve months from this day, and that the services of Mr. Robert Hammond as consulting engineer be immediately dispensed with." In the course of a lengthy speech, Mr. Ward adversely criticised the policy of extensions and the financial methods of the Electric Lighting Committee. The Corporation, he said, were charged at the rate of 6d. per unit, less 10 per cent., while the Winter Gardens Company, which only required heavy current for a few minutes at a time, and therefore kept a large amount of machinery idle, were charged 4d. per unit, less 10 per cent. He thought that the resident electrical engineer, Mr. Hesketh, was perfectly competent to carry out all extensions. After a lengthy discussion, Mr. Ward's amendment was carried by 10 votes to 6. It is rumoured that the delay in passing this vote for £30,000 is only until the results of the November elections are known, the Chairman of the Committee, Mr. Councillor Pearson, going before the electors at the next election.

BLACKBURN.—Some time ago Mr. E. M. Lacey, consulting engineer to the Corporation, brought proposals for extending the electric light mains before the Gas Committee. These were, however, rejected, but when the Town Council discussed the minutes of the Committee, it was, as stated in our issue of August 9th, decided to refer the matter back for reconsideration. It is now stated that the Committee have decided not only to recommend the extensions referred to, but are negotiating for the supply of electrical energy to the local tramways. Would not greater progress be made in electric lighting matters in this town if a special committee were appointed to deal with the subject? Here, as elsewhere, gas and electric lighting interests seem to clash, of course to the detriment of the newer and better illuminant.

CAPE TOWN.—The Town Council have purchased property adjoining their electricity station, for the purpose of making additions thereto, for the sum of £1,681.

CHELTENHAM.—The electric light is evidently "booming" in this town. In our issue of the 9th ult. we referred to the rapid development of the electric light, and at the last meeting of the Town Council Ald. Norman (Chairman of the Electric Lighting Committee) submitted proposals for lighting the principal parts of the town electrically, for which about 50 alternate-current arc lamps would be required to replace more than 300 gas burners. The capital cost was estimated at £3,100, and the annual upkeep £957, or a little over £19 per lamp. A resolution approving these extensions was moved, but an amendment by Mr. Margrett that the light be extended beyond the area recommended by the Committee was adopted as part of the original motion. It has been decided to divide the order for the supply of transformers for a period of 12 months between Messrs. Crompton and Co. and the Brush Company, the former firm to supply all transformers not exceeding 4 H.P., and the latter all of a larger size up to 40 H.P. The electrical engineer's report to the Council contains evidence of a demand throughout the district for current for electric light and power purposes, and the recommendations contained therein have been approved by the Council, including the supply, by Messrs. Siemens Bros. and Co., of an additional 100-kilowatt alternator. Mr. Alderman Norman, in reviewing the work of the past month, said that the record of the electric light was entirely satisfactory. They had either connected up or had applications in hand equivalent to 3,376 8 c.p. lamps. He announced that the Lighting Committee had decided to supply current for power purposes at 3d. per unit. The Council's electrical engineer, Mr. Hamilton Kilgour, has been directed to report as to the lighting of the town clock by electricity, and it has been decided to connect each member of the fire brigade on the electric call system.

CORK.—The question of the lighting of the waterworks by electricity has been referred to Mr. O'Toole (Waterworks Superintendent) to report upon. At the last meeting of the Waterworks Committee the Chairman (Alderman H. Dale) said, as they were now introducing their new turbines, they would have surplus power available, and he was assured they could effect a saving of £50 a year by adopting the electric light, and in addition they would be obtaining a much better light.

DESTROYING TELEGRAMS.—A lad named Johnson, aged 14, messenger, in the service of the Eastern Telegraph Company, has been charged at the Guildhall, London, with wilfully destroying telegraph messages entrusted to him to deliver, and he pleaded guilty to the charge. The Company instituted the proceedings merely to serve as a caution to other boys in the service. Six complaints were made against the boy Johnson, but the Company wished the magistrate to deal leniently with him. In consequence of complaints received, Johnson was questioned, and admitted that he had destroyed the messages, "as he felt too tired to work any more that day." The matter was a very grave one, as the Company's clients were most seriously inconvenienced by the boy's action. Sir J. W. Ellis dealt with the case under the First Offenders Act, and, as the Company desired to act mercifully, bound the lad's father over in the sum of £5 to bring him up for judgment if called upon.

DOVER.—The Harbour Board have decided to erect electric cranes on the Admiralty pier, in order that additional facilities may be provided for dealing with passengers' luggage and mails to and from the Continent. The cranes are to be actuated by alternating current from the Dover Electricity Company's mains, power being required to raise a load of 2½ tons gross about 30ft. in two minutes, for which it is estimated that motors equal to an output of 35 H.P. will be required. Some little difficulty is supposed to exist as to the applicability of alternating current for this purpose, and the Dover Electricity Supply Company have now under consideration various types of plant. It is estimated that when the electric cranes are in full work a saving of 20 minutes or more will be made in the despatch of mail steamers and trains, and, in addition, during the winter months what is always a most irksome and sometimes a most dangerous wait will by this means be avoided.——The lighting of Snargate-street is still a subject for much recrimination at the meetings of the Dover Town Council. On Tuesday the matter was again discussed, and a letter from the Dover Electric Lighting Company was read calling attention to the fact that considerable expense had already been incurred in the matter, and that the delay in carrying out the lighting of Snargate-street was not caused from any action of the Company. A unanimous petition has been presented by the residents of Snargate-street in favour of the electric light, but notwithstanding this, and the resolution passed some back to used arched electric lights, the Council have decided to use incandescent gas lights for the next twelve months.

DUNDALK.—At the meeting of the Town Commissioners on Tuesday it was stated that several offers had been received in connection with the lighting of the town by electricity. The Commissioners at present favour a scheme by which an electric light contractor would supply the necessary machinery and guarantee the working of the plant for a term of years, but on the suggestion of Mr. Maxwell a committee has been appointed to consider and report upon the possibility of converting the present debt of the town into a consolidated loan (repayable in a much longer period), and thus the Commissioners would be in a position to borrow a sum sufficient to at once start an electric lighting system of their own.

EDINBURGH.—At the meeting of the Town Council on Tuesday, a letter from the National Telephone Company suggesting that the Corporation should lay down underground tubes for telephone wires at the Company's expense, was strongly criticised by Sir James Russell, who contended that such action would have the effect of confirming the telephone monopoly in the city. Underground rights should not be granted to any private company. The letter was referred to the Lord Provost's Committee.

ELECTRIC LIBRARY APPARATUS.—The *Morning* states that the new library at Boston, U.S.A., is fitted with a device by which an attendant on the main floor has only to pick out the book wanted, put it in a railway car with a cable attachment, put it off the side switch to the main line, and let it travel round at the rate of 500ft.

Digitized by Google

a minute to a special lift, which drops automatically, as soon as the car is in position, down to the delivery room. When the entry has been made, the car, which has been waiting, rolls back with its load on a return track to the switch from which it started. For the accommodation of hundreds of thousands of volumes, the books are distributed throughout six stories, the aim of the designers being to focus all the books toward a central point, to facilitate delivery. A lift well, long and narrow, which pierced the entire building from basement to roof, was constructed, and in this were set up shafts for three lifts. These are worked by a 10 H.P. electric motor in the basement, each lift being assigned to its special work. To make the system of delivery complete, a miniature railway track, with an 8in. gauge, was run along the lines of the interior courtyard. The cars are made of wire, and travel 300ft. a minute, with 10lb. to 30lb. weight of books in them. At certain points are switches working automatically, by means of which the cars are diverted to whatever part of the building they are destined for. The system by which cards, tickets and messages are despatched to any part of the building is also electrically controlled.

EXETER.—All the material requisite for an autumn battle over the purchase of the local electric light company's undertaking are at hand. The offer of a London company to purchase for £7,000, which offer, in the absence of a better, the Directors of the Exeter Company were disposed to consider, is being made the basis of an attack by one of the leading local journals, which regards the price of £10,000, for which the undertaking has been offered to the Local Authorities, as excessive. The arguments of the local journal have been met with a rejoinder from the solicitors acting for the Company, in which it is stated that the Directors have received from an expert, who has made a thorough investigation, an intimation to the effect that £10,000, the price quoted to the City Council, is the actual value of the undertaking. It is to be hoped that whatever decision is arrived at, the example of Fareham will be avoided.

EXHIBITIONS.—The Vienna I. R. Agricultural Society intend to hold a second exhibition of agricultural machinery, &c., in May, 1896. All branches of industry in any way connected with agriculture will be represented, and there will be a section devoted to tools and machinery used in forestry, sawmills, and celluloid factories, which will also comprise electrical machinery and appliances used in these industries. Provisional applications for space must be made to 13, Herrengasse, Vienna I.

——— An important industrial and agricultural exhibition will be held next year at Nijni Novgorod, and will be open during the whole period of the famous fair. It is stated that the buildings and grounds will be of unusually large dimensions, and an electric railway is being constructed for the convenience of exhibitors and visitors alike.

HAMMERSMITH (LONDON, W.).—The Electric Lighting Committee of the Vestry have been for some time past in negotiation for the purchase of land in Fulham Palace-road as a site for their electric generating station. The Governors of the Latymer Foundations recently offered £2,100 for the land, but the Committee have gone one better, and have offered £2,200.

H.M.S. "VENUS."—This second-class protected cruiser, which was launched from the Fairfield Shipbuilding and Engineering Company's yard yesterday, has three powerful electric search-lights fitted, which are operated from the conning bridges erected fore and aft; the vessel is, in addition, fitted throughout for the electric light.

KETTERING.—Notice has been given for the next meeting of the District Council that a special committee be appointed to consider and report upon the question of the lighting of the town by electricity.

LIVERPOOL.—A special meeting of the City Council was held on Wednesday, when it was finally decided to apply for a Provisional Order to supply electric current within the area of the city as it may exist at the time of granting the Order.

MIDDLESBOROUGH.—Mr. R. Hammond has been appointed consulting engineer by the Corporation, for the purpose of advising them as to their proposed electric lighting scheme.

NEW CABLE STEAMER.—The twin-screw cable-laying steamer which Messrs. Lobnitz and Co. are completing for the Japanese Government is to be fitted complete with cable-laying gear of the most modern design by Messrs. Johnson and Phillips, who have also secured the order for fitting the vessel throughout with electric lighting plant and fittings.

NOTTINGHAM.—The annual report of the Lighting Committee of the Town Council states that there are now 3,564 lamps connected up to the Corporation mains, and that the Great Market-place is now lighted electrically by means of eight 4,000 c.p. arcs.

OLDHAM.—Mr. W. J. Bird Clarke, C.E., held a Local Government Board inquiry last week into the application of the Corporation to borrow, amongst other sums, £15,000 for electric light extension purposes. There was no opposition.

OSTEND.—The Belgian Senate have decided in favour of the purchase by Colonel North of certain Government land on the sea front at Ostend. The purchase includes a concession for a period of 99 years giving the right to lay an electric tramway along the sea-front from the pier. The tramway will be commenced immediately in order to enable this part of the undertaking to be completed by the opening of the Ostend Exhibition in 1897.

OSWESTRY.—At a meeting of the Town Council on Monday a letter was read from the Oswestry Electric Lighting Company stating that current would shortly be available in the compulsory area, except Willow-street, and that the charge for current would be 7d. per unit.

PEMBROKE.—Reference is made in another column to the proceedings in the Courts against the Dublin Southern Tramways Company by the Pembroke Commissioners. An extraordinary scene was witnessed on Monday morning at the works which are being carried out by the contractors for the electric tramway between Blackrock and Haddington-road. While a number of the contractors' men were digging a trench for the underground electric mains, a gang of labourers in the employ of the Commissioners followed and filled up the trench which had been made—much to the enjoyment of both sets of labourers.

REDCAR.—Some time ago the District Council granted a concession for the electric lighting of this district to Messrs. F. H. Stacey and Bennett, of Sheffield, and these gentlemen have now transferred all their powers and obligations to the Redcar Electric Light and Power Company. By the terms of an agreement just approved by the Council the Company undertake to lay all mains and make connections and do all the necessary wiring in connection with the installation, and carry out all the work in accordance with the Board of Trade regulations. They also undertake to supply the Council with electric current for public lighting at 10 per cent. below the charge to other customers. The Council in return are, it is stated, to support only the application of this Company for a Provisional Order, and to oppose any other.

RIPON.—The question of the introduction of the electric light into Ripon came before the City Council at their meeting on Monday. Messrs. Harrison and Co. have already introduced the light at Ure Bank, and the present discussion arose on a proposal to supply electric current to the north end of Ripon. After a lengthy debate the matter was referred to the Gas Committee for consideration, and when this report is presented, a special meeting of the Council will be held to finally consider the matter.

RUGELEY.—At the meeting of the District Council on Wednesday the Lighting Committee were empowered to consider and report upon the question of lighting the public lamps next season by electricity. The Gas Company have just announced a reduction in the charge for public lighting of 1s. per lamp.

SALFORD.—Mr. W. J. Bird Clarke, C.E., held a Local Government Board inquiry on Friday at Salford into the application of the Corporation to borrow £18,000 for electric lighting purposes. The Town Clerk (Mr. S. Brown) said that some time ago application was made to the Local Government Board for power to borrow £50,000, but only £32,000 was then sanctioned, and the present inquiry related to the balance. The Town Council intended to spend £7,770 almost immediately, and they hoped it would not be necessary to hold a further inquiry for the remainder. They trusted that the Board would allow the estimates for the further expenditure to be forwarded to them, and that, upon being satisfied as to the estimates, the Board would sanction the borrowing of the sum required. The Inspector said if the Town Council could now submit a definite proposal for the balance of the £18,000 he thought there would be no necessity for further inquiry. Mr. E. Manville gave details of the scheme, and said that, in regard to the £7,770 now proposed to be expended, £6,270 was for extensions to mains, &c., outside the compulsory area, and the remainder (£1,500) was to be spent on premises, &c.

SOUTHPORT.—The Town Council have been making considerable extensions to their electricity works, and Friday, the 27th inst., has been fixed for the inauguration. Lord-street and the Promenade will be lighted electrically for the first time in the evening.

STAFFORD.—The formal opening of the electricity works takes place on the 25th inst., and a sub-committee has been appointed for the purpose of making the necessary arrangements.

STOCKTON.—A report by the Gas Committee on the electric lighting question will be discussed at the next meeting of the City Council. The Stockton Provisional Order expires in August next.

STOKE.—At the meeting of the Town Council last week a draft agreement embodying the consent of the Corporation to the introduction of electric traction on the tramways was received from the North Staffordshire Tramways Company, but it was decided before formally approving the agreement to send a deputation to Walsall, where the overhead system of electric traction is employed, for the purpose of inspecting and reporting on the applicability of the system to their tramways.

Telephone Trunk Fees.—Complementary to the tabulated list of Post Office trunk-line fees published with our issue of August 2nd, we give above the latest list of trunk-line tolls charged by the National Telephone Company to subscribers for three minutes' conversation between London and various towns, and *vice versâ*. It will be seen that these fees range from 3d. to 4s., against a minimum of 3d. and a maximum of 8s. 6d. on the Post Office service. The list discloses what we have every reason to believe is little known to the public—viz , that communication can be effected direct to London from such places as Margate, Ramsgate, Folkestone, Hastings, Deal, Blackpool, Eastbourne, Tunbridge Wells, and other favourite health resorts, as well as many of the principal commercial centres in the provinces. We are prepared to state that the majority of visitors to many of these towns are totally unaware that telephonic communication is possible between these places and the metropolis, and that this ignorance is by no means confined to visitors. The National Company is not generally credited with hiding its light under a bushel, except in the matter of these trunk connections, and here, certainly, little or no publicity is given. Surely it should be somebody's business to make known the possibility of this through communication, and the National Company should itself give some prominence to the facilities offered at the various exchanges in the provinces. If the traffic is worth encouraging, a moderate outlay would, we think, bring in a considerable revenue. The tariff in many cases is as low as can be expected, and it is reasonable to suppose that when the Post Office takes over these trunks many of the rates will be raised, although, as may be seen in the table published in our issue of August 2nd, there is still one 3d. rate in the Post Office list—that between Colchester and Ipswich. In the above list there are eight towns with which London subscribers can communicate for the sum of 3d., and some of these (as Watford) are of considerable importance.

Telegraphists' Mortality.—The *British Medical Journal* of August 31st contains a brief summary of the evidence taken before the Committee of Inquiry regarding the grievances of telegraphists in the service of the Post Office. Some of the rules of the Post Office of which telegraphists complain are severely handled by the *Journal*. Much complaint is made against the practice of the weekly changing of the hours of work, necessitating change of habits, irregularity of meals, &c., to the great detriment of health. The most startling evidence, however, was that which showed the very large preponderance of phthisis amongst the causes of death in the telegraph service, which produces a mortality greater than that amongst the Sheffield grinders, a trade which has hitherto been considered as most fatal in respiratory disease. A table prepared by Mr. C. H. Garland, a first-class telegraphist, goes to show that in cases of death from respiratory diseases, including phthisis, up to 55 years of age, telegraphists compare with those engaged in the cutlery trade as 59·5 is to 57·3. In the case of the adult male population of this country these diseases are responsible for a death-rate of 24·4 between the ages of 15 and 55, so that they are nearly $2\frac{1}{2}$ times more fatal in the telegraph service than among the ordinary population. This is still more pronounced in the case of phthisis alone, the ratio being: telegraphists 46·6, Sheffield grinders 33·1, and adult males generally 13·8.

Telegraphic Communication in South Africa.—Telegraphic communication between Umtali and Fontesvilla has now been established, and it is proposed to connect Palapye and Belingwe and district with Buluwayo by telegraph.

Wells.—The Town Council have adopted the report of the Lighting Committee, recommending that Dr. J. Hopkinson be retained to advise the Council as to the lighting of the city by electricity, at a fee of fifty guineas and travelling expenses.

Wilmslow (Manchester).—The question of applying for a Provisional Electric Lighting Order for this district was discussed at the last meeting of the District Council, but was adjourned.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by Mr. J. C. Chapman, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

August 22, 1895.

15,787. R. W. Braham. London. An improved electric connecting device applicable to electroliers, electric light standards, brackets, and the like.

15,794. R. Walther. London. Improvements in incandescent filaments and other similar bodies for use in incandescent electric lamps.*

15,826. G. G. M. Hardingham. London. Improvements in the insulation of electric cables. (The firm of Felten and Guilleaume, Germany.)

15,827. B. Ribikoff. London. An improved arrangement of apparatus for the generation of electricity on railway carriages or trains for lighting or other purposes.

August 23, 1895.

15,863. J. G. Statter. Westminster. Improvements in dynamo electric or electro-dynamic machines.

15,868. J. D. F. Andrews. London. Improvements in arc lamps.

15,870. L. H. Mutting. London. Improvements in and relating to electrically controlled weighing apparatus.

15,880. E. W. Jungner. London. Improvements in electric accumulators.

15,886. C. J. Wollaston. London. Improvements in or connected with electric batteries.*

15,889. La Société les Fils d'Adolphe Mougin. London. Improvements in the construction and working of electric arc lamps. [Date applied for under Patents, &c., Act, 1883, Sec. 103, February, 1895, being date of application in France.]

15,895. S. Quincey and J. H. Collins. London. Improvements in electric contract making and breaking apparatus.

August 24, 1895.

15,899. T. F. J. Truss. Cheshire. Improvements in the construction of telephone instruments.

15,952. W. P. Thompson. Liverpool. Improvements in or appertaining to electric lighting apparatus. (Wilhem Kaiser, Austria.)

15,959. P. Stiens. London. Improvements in incandescence lamps.

SPECIFICATIONS PUBLISHED.

Note.—All Specifications can now be obtained at the uniform price of 8d. each.

1894.

14,988. Wise (Solway). Electrolytic cells.

15,219. Müller. Telephonic, &c., lines.

16,162. Engel. Secondary batteries.

17,066. De Ferranti. Electric cables.

17,737. Nisbett. Electric cables.

17,774. Phonopore Company (Limited) and Smith. Electrical signalling apparatus.

18,661. Acme and Immisch Electric Works (Limited) (D. Moy). Electric fuse-holder.

18,662. Acme and Immisch Electric Works (Limited) (D. Moy). Electric switches.

18,809. King. Secondary batteries.

Digitized by Google

COMPANIES' MEETINGS AND REPORTS.

Electric Construction Company (Limited).

The report of the Directors of this Company, which will be submitted at the second annual general meeting of the shareholders on Thursday next, the 12th instant, at Winchester House, Old Broad-street, London, E.C., at 2:30 p.m., states :—

The accounts for the year ended June 30th show a gross profit of £46,690. 15s. 2d., including £2,250. 5s. 7d. brought forward. Deducting interest, outlays on maintenance of buildings, plant, and patents, general expenses, and £5,000 for depreciation, the result is a net profit of £12,091. 10s. 3d., and of this sum the Directors recommend that £1,956. 14s. 5d. be applied in payment of the dividend of 7 per cent. on the Preference shares, and the balance of £10,134. 15s. 10d. be carried forward. The profit and loss account shows a considerable reduction of general expenditure, and, notwithstanding keen competition, a substantial increase of manufacturing profit.

Several important electrical installations have, the Directors state, been successfully completed during the year, production at Bushbury has increased, and the quality of the machinery and plant manufactured has been fully maintained. The works are fully employed on orders, at prices somewhat in advance of those obtainable last year, while the plant and number of workmen have been increased. Among the works in progress special mention is made of the electric lighting installation at Clerkenwell and the electrical equipment of the Hartlepool tramways, and the Directors confidently anticipate that the substitution of electric traction for steam power formerly used at Hartlepool will prove that tramways hitherto worked by horse or steam power unremuneratively may be judiciously adapted for electric traction and yield a satisfactory return on the necessary outlay. Such a result, the Directors feel, cannot fail to give a great impetus to the development of electric traction.

The retiring Directors are Messrs. J. W. Barclay and J. Irving Courtenay, who offer themselves for re-election, as do the auditors, Messrs. James Meston and Co.

NEW COMPANIES, STATUTORY RETURNS, &c.

THAMES VALLEY LAUNCH COMPANY (LIMITED).—This Company was registered on August 30th with a capital of £10,000, in shares of £5 each, to purchase and take over as a going concern the business carried on at Riverside Works, Weybridge, Surrey, and elsewhere, under the style of "The Thames Valley Launch Company," by W. Rowland Edwards, electrical engineer, of Weybridge ; to enter into an agreement dated Aug. 27th last between the vendor and George Willson (for the Company), and to carry on the business of launch and boat builders and owners, electrical and general engineers, suppliers of electricity for motive power, light, heat, &c. The subscribers are: W. Rowland Edwards, electrical engineer (300 shares), S. F. Beevor, electrical engineer (400 shares), George Willson W. H. Smith, T. D. Hollick, engineer, F. W. Hollick, engineer, and George Mansfield, with one share each. The first Directors are S. F. Beevor and W. Rowland Edwards.

BOURNEMOUTH AND DISTRICT ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return to May 24th was recently filed. Of a nominal capital of £50,000, in £5 shares, 5,725 shares had been allotted, and the full amount thereon called.

BRITISH ELECTRO-CHEMICAL AGENCY (LIMITED).—The annual return to April 30th was recently filed. Out of a capital of £50,000, in 5,000 £5 Ordinary and 2,500 £10 Vendors' shares, 2,500 of each class have been taken up, and the latter have been issued as fully paid ; £4 per share has been called on the Ordinary shares.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).—The annual return to August 12th has been filed. The nominal capital is £1,000,000, divided into 150,000 "A" and 50,000 "B" shares of £5 each. 89,261 "A" £3 paid, 17,139 fully-paid "A" and 23,564 fully-paid "B" shares have been taken up, and the 17,139 "A" and the "B" shares have been issued as fully paid, while the sum of £2. 10s. per share has been considered as paid on the other "A" shares. Resulting from a call of 10s. per share on the 89,261 £3 paid "A" shares, the full amount of £44,630 10s. has been received.

MANCHESTER EDISON-SWAN COMPANY (LIMITED).—The annual return to August 8th has been filed. The nominal capital is £550,000, in 50,000 "A" shares of £9 each, and 10,000 "B" shares of £10 each. 20,000 of the former and all of the latter have been allotted. The full amount has been called on the "B" shares, but only £1. 10s. per share on the "A" shares.

NEW PHONOPORE TELEPHONE COMPANY (LIMITED).—An agreement recently made provides for the purchase from the Phonopore Company (Limited) of letters patent for Great Britain (17,774 of 1894) for improvements in electrical signalling apparatus, and the French and Russian patents for the same invention, and for the exclusive licence to use and enjoy certain patents, including four British, two French, one Russian, two Austrian, two Belgian, one Canadian, one German, two Indian, two Italian, one Portuguese, two Spanish, one Swiss, one American (U.S.A.), and three Argentine, for improvements in telephony, telegraphy and in electrical receiving instruments and relays. The purchase consideration has been fixed at £2,000, payable £1,000 in cash and the allotment of 1,000 fully-paid Founders' shares of £1 each in the New Phonopore Telephone Company (Limited).

RICHMOND (SURREY) ELECTRIC LIGHT AND POWER COMPANY (LTD.).—The annual return to December 31, 1894 (as no meeting was held during that year), was not filed till August 31st last. Of a capital of £50,000, in £5 shares, 4,066 shares have been allotted, and the full amount called.

CITY NOTES.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Pric of silver, 30 9/16d. per oz. (Sept. 5th). Consols (2¾ per cent.) 107⅜—107½ for money, 107 7/16—107 9/16 for account (Sept. 5th); 2½ per cent. 106—106¼. Stock Exchange Settling Days: Consols, Oct. 1st; Stocks and Shares Continuation Day, Sept. 10th ; Ticket Day, Sept. 11th ; Pay Day, Sept. 12th ; Mining Shares Carry-over Day, Sept. 9th ; Railway and Foreign Stocks, &c., Sept. 10th—12th.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ending September 1st were £786, against £794 in the corresponding week of 1894, a decrease of £8. The total receipts for the half-year amount to £7,669, against £7,735 for corresponding period of 1894, a decrease of £66.

COMMERCIAL CABLE COMPANY.—The Directors of this Company have declared a quarterly dividend of 1¾ per cent., payable on October 1st. The transfer books will be closed from 20th instant to October 2nd.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of August, 1895, were £1,957, against £1,583 in the corresponding period of last year, an increase of £374.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of August amounted to £62,661, and to £60,279 in the corresponding period of last year, an increase of £2,382.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of August amounted to £54,357, and to £44,638 in the corresponding period of 1894, an increase of £9,719.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this Company in August were £28,000, and the total receipts for the period from January 1st to August 31, 1895, £202,800, against £180,000 and £182,200 in the corresponding months of 1893 and 1894 respectively.

JAPAN.—As in many other matters, Japan is stated to be a shade in advance of Great Britain in the matter of dividends of electric lighting concerns. It is reported that the shareholders in the Kyoto Electric Light Company have recently received a dividend of 18 per cent. per annum. Complete particulars are wanting.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ending 1st inst. amounted to £1,272. The amount for the corresponding week last year was £1,152. Increase, £120.

MILVER PORTABLE ELECTRIC BATTERY SYNDICATE (LIMITED).—The statutory meeting of this Syndicate was held on Monday at Birmingham, Mr. Hyman Levetus presiding. The Chairman explained that the Company was a private limited one—all the shares having been subscribed for. He congratulated the shareholders upon the property they possessed, and calmly anticipated a return equivalent to 20 times the sum invested, although no date was fixed when this return was likely to happen. The Company had met with very much discouragement from men who had more or less scientific knowledge, who had pointed out that it was impossible for them to attempt to compete with those whose electric current was generated by engines and dynamos ; but in reply to these objections he said they did not use zinc, but a substitute with a special solution costing about one-twentieth the price of zinc. He thought there was an important future for them, because they could supply power at 4d. per horse-power, and when their electric horse was not at work it cost nothing, and when charged it would run for 10 hours without refreshment, and could take its next meal in 10 minutes, and when the law had been altered to permit the working of vehicles by electricity along country roads there would be no necessity for light railways. Every farmer could have his own produce waggon and take it along the roads at the highest rate of speed allowed by the authorities. The tramways in Bristol Road had not been successful owing to the dead weight and uncertainty of the accumulators. The weight of an ordinary accumulator for 10 hours' discharge was from 800lb. to 1,500lb., while the outside weight of a Milver battery was 400lb. They could have a Milver battery large enough to light a cathedral, or small enough to carry in the hand for a bed-room candle. To bring about these results they had had to construct new receptacles. They hoped shortly to call the shareholders together and show them a horseless carriage and electric lighting with Milver batteries. The Company had applied for patents in 15 countries, and provisional protection had been obtained. They had been authoritatively informed their patents were all valid. In regard to the construction of the Milver battery they had been told by experts that the difficulties of polarisation were insuperable, and that the cost of zinc was too prohibitive; but the impossible had been overcome. Their light would not exceed a cost of 6d. per unit. There were only a few shareholders present at the meeting, and it is not reported whether anyone asked for an instalment on account of the 400 per cent. profits prophesied by the Chairman.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ending August 30th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,038.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the half-month ended August 31st are £1,538, as compared with £1,719 in the corresponding period of 1894.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 904. [No. 20. Vol. XXXV.] FRIDAY, SEPTEMBER 13, 1895. PRICE SIXPENCE.

NOTES.

THE vision of transcendent knowledge which Prof. W. M. HICKS has conjured up in his Presidential Address before Section A, which will appear in our next issue, is still far distant; the day is not yet when "all physical phenomena will be a branch of pure mathematics," and when we, viewing all phenomena as "manifestations of motion of one single continuous medium," shall replace the study of dynamics by the study of that quintessence of finality, the equation of continuity. We will not stay to question in detail whether, in the evident trend of modern science along converging paths towards unity, we are justified in believing that "the ultimate aim of pure science is to be able to explain the most complicated phenomena of Nature by the fewest possible laws from the simplest fundamental data." The trend is evident; but if the aim of science be to find out Nature as she is, it must first be proved that Nature herself is explicable in these simplest and most unified terms. We can point to at least one set of phenomena in Nature—the mental and its allies—which are likely to baffle Prof. HICKS's analytical reagent for all time. However this may be, the live load of scientific thought is increasingly imposing itself upon the properties of the ether for its support; and questions of physical phenomena are more and more numerously resolving their issues into the highly debatable ground of the mechanism and behaviour of that subtle substance. The wreckage of rejected theories of the ether, says Prof. HICKS, is appalling. Yet all this disastrous running on to rocks will not have been altogether calamitous if we are in future led to look out more carefully for rocks ahead. The danger lies in simplifying ordinary phenomena at the expense of the simplicity of the ether. We gain nothing if we rob material phenomena of their complexity in order to make a present of that complexity to the ether. The action of an engine is none the more readily explained when its working parts have been made invisible by the guard plates with which we may cover it in; the theory of a Willans engine gains nothing in simplicity on account of the enclosing crank case. At all costs, if we are to simplify everything by means of the ether, let us have an ether which is in itself simple, or at any rate less complex than that which it is designed to explain.

TAKE, for example, that ingenious speculation of which Prof. HICKS gives some account, in which the ether is conceived to be composed of a medium "spaced into rectangular boxes," within which the fluid medium "streams up in the centre of the box, then turns round, flows down the sides and up the centre again," like a badly-packed Hill's vortex, which "can swallow another and retain it inside in relative equilibrium." Or take the hypothesis that the ether consists both of a primary raw stuff and a secondary cellular stuff, within which are embedded the atoms of matter, either composed of the primary or secondary stuff, each atom being connected to other atoms by means of vortex ether filaments. In what way, may we ask, does either of these conceptions, whether plainly stated or garbed in the language of the mathematics from which the idea is evolved, assist us to any better understanding of the How or the Why of Nature? To what extent can such complex speculations, located in infra-microscopic, infra-atomic spaces in an invisible medium, supply us with anything better than a new shibboleth, with which to formulate our ignorance of the ultimate end of phenomena? Where, in these conceptions, are we to discover that step towards the simplification of laws and the narrowing down of data, which it is said to be the aim of science to achieve?

PROF. L. F. VERNON-HARCOURT makes a very plausible point towards the end of his Presidential Address to Section G, which we hope to find room for next week. Physicians, he remarks, try to cure people when they are ill, whereas engineers do much to render doctors unnecessary by maintaining the community in good health by the provision of good water supplies, good drainage systems, and facilities for getting away to "fresh woods and pastures new" when the strain of business threatens to result in a breakdown. Inasmuch, therefore, as prevention is better than cure, mankind is more beholden to the preventive benefits of engineering than to the drugs of the medico. This is, however, but half the case. Speaking generally, the operations of the medical profession do not give rise to new diseases as fast as old ones are stamped out. The same cannot be said of the operations of the engineering profession, by which the socially and physically unhealthy aggregations of human beings that characterise the age have alone been made possible. True it is that incidentally the engineer of one branch tends to ward off or mitigate the evil effects of the labours of the engineer of

Digitized by Google

another branch. But it does not seem more rational to shower praise on such a performance than on the performance of an ingenious individual who is engaged in knocking down ninepins of his own setting up.

Prof. Harcourt is in favour of the engineering degree. So are we, provided the antecedent practical training is sufficiently thorough. To grant engineering degrees for mere book learning and college laboratory proficiency is, we think, a course full of danger to the public and disappointment to the graduates.

It is interesting to note that the technical literature of even inland navigation is accumulating so fast that a comprehensive and authoritative catalogue has become a prime necessity. The last scene of all of this strange eventful history will, no doubt, be a catalogue of catalogues, with half the engineering profession engaged in abstracting and indexing the records of the other half.

The noise of the Niagara word-fall still continues, and the special number of *Cassier's Magazine*, to which we alluded last week, is not, alas, to be the final fanfare. In the current number of *Blackwood* will be found an exceedingly lively and discursive article on "Harnessing Niagara," from the pen of Prof. George Forbes. It would be difficult to imagine a disquisition better calculated to stir up the dying embers of a very unpleasant controversy, redolent of personalities, professional prejudice and mistaken patriotism. As one might naturally suppose, the tale of the harnessing of Niagara, as told in "Maga," is meant to tickle "the ear of the groundlings," and contains no engineering information not previously available. Nevertheless, Prof. Forbes's homily has its educational value. Engineers will learn that Americans are neither inventive nor humorous, they will learn not a little as to what is and what is not professional etiquette; they will learn how to deal with presidents and vice-presidents, how to manage millionaires and associate with the Potters and Lorillards, and if they wish to know, without the trouble of a trip to the United States, how the average American strikes the average Englishman, Prof. Forbes's character sketch will serve that purpose as well as anything we know of. The author is inclined to believe that the "splendid results" attained at Niagara are due not only to engineering skill but to the "exercise of tact, judgment and forbearance, combined with firmness." We also are quite ready to believe this, though we look in vain for these particular qualities in the article in question.

We cannot help thinking that it is about time to pass an Act of Oblivion in connection with all that took place with reference to the design and construction of the Niagara plant. The dispute has not at any time been particularly edifying, and it now bids fair to become wearisome. At any rate all further contributions to the discussion might be confined to the American technical Press. It is difficult to see in what way these minutiæ can interest the British public, and yet the greater part of the discussion is taking place in the columns of *The Times*. Only on Tuesday last there was a column-long letter from the Westinghouse Company, the most important part of which is that Company's account of the relative parts played by it and Prof. George Forbes in the design of the Niagara generators. This account runs as follows:—

The Cataract Construction Company, in September, 1893, submitted to us plans for a 5,000 H.P. generator, saying that such plans had been prepared by their engineers, and asking us to make a tender for its construction and erection. The careful consideration of the plans submitted disclosed the fact that, if constructed according to such plans, the generator would be a failure, and this Company thereupon refused to tender on the drawings and specifications presented. We however, offered to accept the general form of generator, and to redesign it so that it would be a perfect machine mechanically and electrically, and to submit new plans and specifications upon which the Company could tender. This was agreed to by the Cataract Construction Company, and the generators now in use at the Niagara Falls were built by us according to plans and specifications prepared by our own engineers. There is about the same difference between the machine designed by Prof. Forbes and that designed by us, as there is between the picture of a man and the man himself—the appearance externally being very similar, but internally there is no resemblance whatever.

The non-technical Press is not so often wrong in its science as lacking in a due sense of proportion. Thus, in an interesting article in the *New York Law Review*, entitled "Liability for Escape of Electricity," we learn that "telephone lines are invariably the sufferers, since the relatively weaker current which they employ and the greater delicacy of the instruments used for the transmission of speech, render them easy victims of the stronger currents and less susceptible machinery of the railway lines." There is no doubt, of course, about a telephonic current being "relatively weaker" than that sent out by an average street railway generator; but one might just as well speak of a gnat as being relatively weaker than an elephant.

Battersea Polytechnic Institute.—Full particulars of the day and evening classes at this Institute are given in the prospectus of 1895-96, just to hand.

Cable Interruption and Repairs:—

	Date of Interruption.
Aden-Zanzibar	September 2, 1895.

The Fatal Accident on Electric Tramway at Portrush.—The Board of Trade inquiry will be held on Wednesday next, at 11:30 a.m., in the Town Hall, Portrush.

The Length of the Metre.—Last Tuesday's sitting of the International Metric Congress was entirely devoted to the question of the comparison of the metre with the wave-length of light. The result is that the metre is said to be 1,553,663 times the length of the standard wave of red light.

Electric Launches in Copenhagen.—A company was formed some time ago in Copenhagen for the purpose of starting electric launches on some small lakes within the town in lieu of petroleum launches, which had been very far from a success. The company has secured a 30 years' concession. It was in contemplation to have the accumulators made in Germany, but they are now being manufactured in Copenhagen, as the German firms could not guarantee sufficiently early delivery.

Electric Lighting in Chelsea.—In the thirty-ninth annual report (1894-95) the surveyor to the Chelsea Vestry reports that the customers of the Chelsea Electricity Supply Company are now 598 in number, an increase of 98 in the year. Only one application was made during the year to have a meter tested; it was found to be registering 1·3 per cent. *under* at full load, to be correct at half load, and 15 per cent. *over* at a light load. As the load was very light at these premises a smaller meter was inserted by the Company, and the cost of the test was paid by them. Up to the present the difference in cost of the electric lighting of the Town Hall as compared with gas is inappreciable.

The Telephone in Paris.—Government purchase is evidently no panacea for telephone troubles. M. André Lebon, Minister of Commerce and Posts, announces, says the Paris correspondent of *The Times*, "some improvement in the telephone system for next January, but the deficit is pleaded as an excuse for not as yet reducing the subscription in Paris, which is heavier than in other large cities. The possibility of increasing the revenue by lower rates and more subscribers does not seem to be considered. We must, therefore, be thankful for such small mercies as a reduction from 50c. to 25c. for a three minutes' conversation in Paris, a reduction from 160fr. to 50fr. for a subscriber's supplementary wire, and the abolition of the surtax on clubs and restaurants."

The Electric Furnace—Dr. Baxeres Torres, of the Technical Association of London (Limited), writes us as follows:—

SIR: In the interesting Paper upon electric furnaces, by Mr. Ch. Street, which, as read before the Société Internationale des Electriciens, you quote in your issue of the 23rd ult., as well as in the summary of patents with which the Paper closes, I am surprised to find that, though many French patent office records have been duly extracted and included, yet no mention whatever is made of my original French patent No. 220,519, March, 1892, nor of the four additions thereto—viz., three in the following April and the fourth in May of the same year. I have been working earnestly at the development of this furnace since I took out the above patent, and I am happy to inform you that now an English company is established to exploit and put into practical work my various metallurgical processes and patents, under the title of The Technical Association of London (Limited), with offices in London, and somewhat extensive experimental work with powerful machinery in St. Anne's Court, Wardour-street.

Paper Insulated Cables.—Notice is given that it is the intention of the Amos Emerson Dolbear and the British Insulated Wire Company of Prescot to present a petition to Her Majesty in Council praying that the term of Patent No. 1,368 of 1882 may be extended. Notice is further given that on November 1st next, or on such subsequent day as the Judicial Committee of Her Majesty's Privy Council shall appoint for that purpose, application will be made to the said Committee that a time may be fixed for hearing the matter of the said petition, and notice is also given that any person or persons desirous of being heard in opposition to the petition may enter a caveat to that effect in the Privy Council on or before November 1st next. The patent in question relates to the construction of an electric cable consisting of a paper tube containing a copper conductor of smaller diameter, which conductor either rests at the bottom of the tube or is supported in its centre by an open spiral of cord.

Working Expenses on Electric Railways.—The *Railway Age* of America expresses the opinion that on its side of the Atlantic "electric railways have not yet been in operation long enough to fairly test the comparative cost of operation and maintenance, although some claims for great economy have been ventured. A statement of the gross and net earnings of the electric lines in five cities—Buffalo, Columbus, Lehigh, Scranton and Indianapolis—appears to show that the percentage of operating expenses to earnings was, respectively, 53, 51, 58½, 68½ and 59. If these widely-varying results may be taken as at all representative they show an average of about 60 per cent., which, compared with nearly 70 per cent., the average of the steam railways of the country, seems favourable. But when the time for renewals of electric appliances has come and gone statistics of expenses will have much more value than they now can possess.' In other words, when it is seen how much foresight there has been to provide against depreciation, we shall the better know whether these are or are not the true relation between earnings and working expenses.

A Fortunate Lightning Stroke.—Writing to *The Times* on the subject of lightning, Mr. C. Tomlinson, F.R.S., states that in the sixties it was generally held at the Admiralty that lightning conductors attracted lightning instead of warding the stroke off. Snow Harris had strenuously recommended his metallic conductors for ships, and had abundantly proved what important losses had occurred through their absence. He had obtained permission to erect his conductors on ten ships destined for foreign service, and in one of them a flagstaff had been put up above the conductors, and was consequently shattered by a lightning stroke, but no further damage was done. This trifling accident seemed to justify the order for the removal of the conductors from each ship on its return home. At Devonport a bifurcated discharge had most singular results. Sir John Rennie was employed by the Admiralty to erect two victualling houses at Devonport. Each was furnished with a granite chimney rising 60ft. above the roof. One of these was furnished with a lightning conductor; but before the other was erected Rennie called on Snow Harris with the indignant complaint that the charge for lightning conductors had been struck out of the estimates. Harris said, "Well, never mind, Nature will avenge us!" Never was prophecy more amply fulfilled. A bifurcated stroke of lightning fell on the two victualling houses; the protected building suffered no injury, the unprotected chimney was torn open, with other damage to the building, to the admiration of the British Association, which met at Plymouth that same year, namely, 1841. This fortunate bifurcation at once made lightning conductors popular.

The Compagnie Française des Cables Télégraphiques.—The Venezuelan *Gacetta Official* of January last announced the grant, for a term of 50 years, of two exclusive concessions to the Société Française des Télégraphes Sous-Marins (now united with the "P.Q." Company under the title of the Compagnie Française des Cables Télégraphiques), the one being for cable communication, direct or indirect, between Venezuela and the United States, and the other for cables on the Venezuelan coast. These concessions were ratified by the Government of the Venezuelan Republic in June. It is reported that the Compagnie Française claims also to have obtained landing rights in New York for a cable extension, thence down to the West Indies, with a view to thus bringing their Venezuelan, Brazilian and West Indian cable system in direct communication, *viâ* France, with Europe, and that after the deep-water repair of their Penzance-St. Pierre cable, upon which the "Faraday" is now engaged, has been effected, they will proceed with this extension. The report would seem to be based upon a misconception of United States law, which forbids the landing on American shores of cables, for which exclusive landing rights elsewhere are held. Should the "Faraday" fail in repairing the deep-water break above-mentioned within two months, the repair will probable be abandoned for the season, as was that of another Atlantic cable upon which the same vessel was so long at work last summer. According to the *Bulletin de l'Electricité* of the 1st inst., the Compagnie Française are paying for the charter of the "Faraday" no less than £300 a day.

Military Telegraphy at the New Forest Manœuvres.—The following extract from a letter of *The Times* correspondent present at the recent military manœuvres in the New Forest will be read with interest. The incident referred to is the outpost duty practice at night which took place:—

"And here came again into play the 'wire' as an invaluable aid in war. From the tents of the two generals lines were laid to the several pickets and detached posts, with orders to reel up and retire with the pickets if these were compelled to fall back, but to at once reopen communication when the pickets halted. In the Northern force the sapper clerks were at the ends of the 'wire' for the long period of 26 hours. In the Southern force the general, pushing out at daybreak some cavalry, gave the clerks a little rest. But the Northern general, owing to the nature of the duty specially imposed upon him, could not afford to dispense with the 'wire' for a single instant. . . He preferred to be in conversational contact with the picket officers, to hear their reports, to ask them himself for information required to complete or supplement those reports; and this he did through the 'wire,' and thus exactly at the right moment he was able to give the order to strike the camp, move off his force, and ride away himself to the new battlefield, not giving up the 'wire,' but to all intents and purposes tying it to his horse's tail for subsequent use. . . As affecting the movements of the troops, the semi-close ground has rendered frequently unavoidable the breaking up of larger units into smaller ones, temporarily out of touch and sight of each other. This disintegrating process would make itself felt much more in the really close country of cultivated England. It is the 'wire' alone that can effectively connect those out of sight but still very much in mind. Here daily has been seen accompanying the generals as they moved about, a well-horsed cart or waggon capable of being taken across country or at racing pace along roads. On the vehicle sits the telegraph clerk, in a box by him is the telephone, and from it streams the 'wire' to the unit temporarily lost to view, or perhaps executing a wide turning movement; and thus the general is kept accurately informed of the position and the progress of the absent unit. It is satisfactory to be able to report that German officers have admitted that in field telegraphy our Army is far ahead of their own."

WILLIAM STURGEON.

William Sturgeon, the electrician and natural philosopher, was born (on May 22, 1783)* at Whittingham, a village close to the Westmorland border of Lancashire, and near the town of Kirkby Lonsdale. His father, John Sturgeon, was a clever but idle shoemaker, who came from near Dumfries, and married Betsy Adcock, daughter of a small shopkeeper in Whittingham. William Sturgeon's early years were passed under conditions of great hardship. His father devoted more attention to poaching salmon in the river Lune than to his trade, and young William had to assist in the nightly raids. At 13 he was apprenticed to a shoemaker at Old Hutton, near Kirkby Lonsdale, and was doomed to be even more cruelly treated than at home. Yet, amid all the hardships that a bad master was then able to inflict on an apprentice, and although surrounded by every temptation and evil influence, he contrived to learn something of music and several mechanical arts, such as the repairing of clocks and watches.† At the age of 19, seeing little prospect of improving his position as a journeyman shoemaker, he enlisted in the Westmorland Militia, and in 1804—two years later—he became a private in the 2nd Battalion of the Royal Artillery, and remained in the Army as a "private and gunner" until 1820. This period included the stirring times of the Peninsula War and the Battle of Waterloo, but an examination of the R.A. records shows that Sturgeon was never on war service.‡ His leisure time was devoted to his trade, to making artillery models and electrical instruments, and to study. "The soldier's life," says Major Murdoch, "was then more monotonous and less arduous than now; and there not being any meal after dinner, many unbroken hours of leisure were at the command of the soldier—for good or evil. 'Out lights' was sounded at 8 o'clock in winter and 8:30 p.m. in summer; but with the aid of a rush-light, and covering the windows with blankets secured by forks, Sturgeon was in the habit frequently of preferring his studies to sleep—the mess conniving at his breach of the regulations in consideration of his geniality and occasional 'odd jobs to their boots.'" His attention was directed to electrical science by a terrific thunderstorm,§ and he resolved to fit himself for its study. He worked at mathematics and learnt sufficient Latin and Greek to understand the meaning of scientific terms. French, German and Italian he was finally enabled to read with considerable facility. Thus prepared, he entered upon the general study of natural philosophy, but the phenomena of electricity and magnetism had the greatest attraction for him.

He left the army at the age of 37, his conduct, according to the testimony of his commanding officer, having been "altogether unimpeachable." He then followed his trade as a bootmaker in a shop at Artillery-place, Woolwich, but he kept up his interest in science especially by constructing apparatus. His pursuits during this time will be best given in his own words: "After leaving the service of the R.A. in 1820, and as my slender finances presented opportunities, I turned my attention to scientific inquiries, and to the construction of some of those philosophical apparatus which from my boyhood I had been an admirer of, but which during *my* service at least a military profession precluded all further knowledge of than which was to be derived from books of science—a species of commodity at that time exceedingly rare in the Army, even in the distinguished branch to which I had the honour to be ong. My first step towards constructing apparatus was the purchase of an old lathe and a few tools to work with. My stock of tools, however, was very limited, from a want of means to purchase more, so that many rude substitutes were brought into requisition; and as I had no practice either at the lathe or the vice, my first essays in apparatus-making were necessarily deficient of those elegancies of structure and refinements of workmanship which always characterise the productions of regular instrument makers. Notwithstanding these disadvantages, however, hope and perseverance surmounted every difficulty that was met with, and I soon found myself capable of constructing such pieces of apparatus as I immediately wanted for my purpose; and it was not long before I found purchasers for others, even amongst the first-rate instrument makers in London." His philosophical pursuits brought him in contact with Marsh the chemist, Barlow, Christie, and Gregory. Owing to their influence he was appointed Lecturer on Experimental Philosophy to the Hon. East India Company's Military Seminary at Addiscombe. This college was originally founded for the appropriate education of young men who desired a commission in the artillery or engineer corps of the Company's army in India. He also lectured at the Adelaide Gallery of Practical Science, Addiscombe. In 1840 he was invited to Manchester to act as superintendent of a new institution—the Royal Victoria Gallery of Practical Science—which was established to commemorate the Queen's marriage. The aims of the founders were set forth as follows:—

1. To provide a permanent collection of models and apparatus to illustrate the arts and manufactures, and for the display of experiments combining philosophical instruction with general entertainment.

2. To afford facilities for demonstrating *practically* such elementary principles in mechanism, chemistry, and other departments of practical science as admit of direct application to the useful arts.

3. To exhibit the progress which has been gradually making and which may still be made in branches subservient to productive industry.

4. To stimulate research and foster inventive talent by honorary or pecuniary rewards, and to furnish to the junior members of the community such attraction as may allure them to the acquisition of valuable knowledge by affording them pleasure in the pursuit of it.

Sturgeon, now 57 years of age, entered on his duties early in 1840. On March 3rd he commenced the first course of lectures, and in June the Exhibition Gallery was formally opened. Most energetic attempts were made to bring success to the Institution by exhibits of apparatus, models, &c., and making the lectures as popular and interesting as possible. The lectures related to electricity and magnetism, optics and mechanical philosophy. The latest inventions, such as electrotyping and the electric telegraph, were exhibited; nevertheless, the Royal Victoria Gallery failed for want of adequate financial support. An attempt was then made to found an institution on similar lines, called the Manchester Institute of Natural and Experimental Science. The first course of lectures related to Mechanical Philosophy, and Sturgeon commenced the series by observing that this was the second time in Manchester that it had fallen to his lot to open the lecture department of a newly-formed scientific institution; and "although in the first instance this hope of success was doomed to disappointment (from a cause which was not properly explained), he still felt a confidence that in this town the love of scientific investigation among the inhabitants was not a topic of controversy, but was established beyond dispute. Under these circumstances there seemed no reason to suppose that a scientific institution should fail in being supported in this metropolis of manufactures." Nevertheless, Sturgeon's hopes were again disappointed, and at the age of 61 he was thrown out of regular official engagements, and had to rely upon chance lecturing and literary work for the support of himself and his family. He remained in Manchester lecturing from time to time at the Royal Institution and the Mechanics' Institution until 1846, suffering from ill-health and poverty. In September of that year he went to Biggins, near Kirkby Lonsdale, to recruit after a long and serious illness; and, notwithstanding his shattered health and depression of mind, he made certain observations, and wrote "Three Accounts of the Aurora Borealis and the Formations of Clouds as observed in the locality of Kirkby Lonsdale." In August, 1847, Lord John Russell was induced to grant him the sum of £200 from the Royal Bounty Fund. Sturgeon being now 64 years of age, and it was strongly urged by his friends that this sum would only release him from temporary embarrassment, and that he ought to be pensioned. These representations succeeded, and in July, 1849, his name was placed on the Civil List for a pension of £50 per annum.

* This date is taken from the register by the Rev. Edward Pigot, of Whittingham.

† See "A Short Account of the Life and Writings of the late William Sturgeon," by J. P. Joule, *Mem. Manchester Literary and Phil. Soc.*, 1857.

‡ I am greatly indebted to Colonel A. E. Turner, A.A.G., R.A., for this information, and also for the following pamphlets: "The Cantor Lecture, 1890—William Sturgeon," by Major R. H. Murdoch, R.A., reprinted from the *Proceedings* Royal Artillery Inst., No. 2, Vol. XIX.; and "A Distinguished Gunner," by the same author, from *Proceedings*, R.A.I., No. 6, Vol. XIII.

This was, however, of little service to him. He never entirely recovered from a severe attack of bronchitis, from which he suffered when living in Greenheys, and he removed to the highest part of Manchester—Prestwich—in the hopes that the air there might be better suited to him. On Thursday, November 28th, 1850, he caught a severe cold, and although assiduously attended by his friends Leigh and Burrow, he died on Sunday, December 4th. He was interred in Prestwich churchyard in the presence of Joule and other scientific men. The gravestone—an ordinary flat one—bears the simple inscription :—

WILLIAM STURGEON,
The Electrician,
Born 1783, died 1850, aged 67.
Also
MARY STURGEON,
Died October 2, 1867, aged 77.
ELLEN, wife of Luke Brierley,
Died January 19, 1884, aged 51.

Soon after entering the Royal Artillery, Sturgeon had married a widow, Mrs. Hutton, who had a shoe shop in Woolwich. They had three children, who all died in infancy. In 1829 he again married. His second wife was Mary Bromley, of Shrewsbury, by whom he had one daughter. On the death of this child they adopted his neice, Ellen Coates, who married Luke Brierley. It may be interesting to give a list of Sturgeon's places of residence:—(1) 8, Artillery-place, Woolwich; (2) Westmorland Cottage, Old Kent-road; (3) 55, Burlington-street, Hulme, Manchester, described as Lecturer, Royal Victoria Gallery; (4) Albert-terrace, Radnor-street, Hulme, described as Lecturer, Manchester Institution of Natural and Experimental Science; (5) 20, White-street, Hulme; (6) 13, Wash-lane, Prestwich, where he died. This house is still standing. It is the last of the old tall houses, and when Sturgeon lived there it was the last in the lane.*

With the aid of the accompanying steel engraving some idea will be obtained of Sturgeon's personal appearance. The engraving is taken from a portrait found pasted in a volume of Sturgeon's researches, bought from a bookstall in Shudehill Market, Manchester, by Mr. J. B. Shaw. It has been compared with an oil painting in possession of a relative, and has been submitted to those who remember Sturgeon, and is no doubt a good likeness. It is the first time that an engraving of Sturgeon has been published, although many attempts have been made to obtain a portrait for the purpose. The autograph has been obtained by engraving a tracing of the signature from the book of Candidates of the Manchester Literary and Philosophical Society. It represents the general characteristics of his handwriting, but it should be somewhat bolder, his penmanship being thick, heavy and rather clumsy, possibly from his service in the Artillery. This regimental record furnishes us with the following particulars :—

WILLIAM STURGEON, Senior.†

Rank and name.		Enlistment.					Born.		Trade.	Read and write	Description.
		Age.	Height, &c.	Date.	Place.	By whom.	Parish.	County.			
Gunner and driver.	William Sturgeon.	21 years.	5ft. 8½in. Chest, 35in.	April 23, 1805.	Hull.	Capt. Desbrisay.	Whittington.	Westmoreland.	Cordwainer (Bootmaker).	Yes.	Hair .... Brown. Eyes .... Grey. Complexion, Fresh.

Discharged at Woolwich to pension of 1s. a day, October 1, 1820.
Died in Manchester district, December 18, 1850.

* From information collected from the signed articles in the Scientific Researches; Manchester Directory; Mr. George Middleton, Assistant Overseer of Prestwich; the Somerset House Records; and the Rev. F. J. Jones, Rector of Prestwich.

† Another William Sturgeon also enlisted about the same time, and was better known as "Fighting Billy," on account of having been in more battles in the Peninsula than any other man in the ranks.

Joule was intimately associated with Sturgeon, and was able to speak definitely regarding his character. He says (*Mem. Lit. and Phil. Soc.*, Manchester, 1857, p. 83): "Mr. Sturgeon was of a tall and well-built frame of body; his forehead was high, and his features were strongly marked. His address was animated, and his conversation, as it generally is when the mind is stored with knowledge, pleasing and instructive. His style of writing was at once vigorous, lucid and graceful. In friendship he was warm and steady, in domestic life affectionate and exemplary. He had a noble mind and a generous heart. . . . He was a close and sagacious reasoner and an unsparing exposer of error. He detested quackery and false pretensions, sought diligently for truth, and loved it for its own sake. A diligent accumulator and observer of facts, eager in the pursuit of information of whatever kind, and in communicating his store to others, under more fortunate circumstances he would probably have left a name unsurpassed in the scientific history of his time; as it is, he will always be remembered as a distinguished cultivator of natural knowledge." Another friend, Dr. Leigh, in an obituary notice (*Manchester Examiner and Times*, December 14, 1850) says: "As a lecturer he was distinguished by a plain but manly and vigorous style; he never aimed at effect, but, thoroughly master of his subject, delivered himself with such clearness and perspicuity that it was impossible to mistake his meaning. . . . He was in all respects a fine, frank, manly fellow." Inquiries have been made from several persons now living who remembered Sturgeon, and from their letters the following extracts will be worth quoting:—Mr. Leo H. Grindon, the botanist, says: "I remember him well; he was very quiet and self-contained in manner; his countenance was inclined to be roundish, very calm and placid, of no particular line." Mr. J. Taylor says: "I was present at Sharp and Roberts' works, Great Bridgewater-street, about the years 1841-2, when Mr. Sturgeon, whom I should suppose would stand 5ft. 10in. high, and appeared to be of rather robust build, and of a healthy appearance. He had a locomotive engine, with 'steam up,' in the erecting shop, raised on blocks of baked wood, and while standing on an insulated stool held an ordinary spade in the steam, which was escaping at high pressure from the safety valve. The spade was connected by a copper wire to a gold-leaf electrometer, and when brought in contact with the steam the gold leaves separated, as usual, thus proving the presence of electricity in steam on its escape from the boiler." Alderman Harry Rawson, one of the oldest public men of Manchester, says: "I remember Mr. Sturgeon, heard him lecture, and visited the Victoria Gallery several times. He was a tall, big man, with a strongly marked face that is commonly considered plain. I should not say he was of clumsy build, but certainly he was not an elegant figure."

Sturgeon was a most industrious writer. I have prepared, as far as I have been able, a list of his published works. Some of these are now but rarely to be seen :—

[1830.] "Experimental Researches in Electro-Magnetism, Galvanism," &c. This is a pamphlet describing an extensive series of original experiments. He points out the advantage of amalgamating the zinc plates of voltaic cells in preventing local action.

[1836.] Sturgeon establishes a monthly periodical—"The Annals of Electricity, Magnetism and Chemistry; and Guardian of Experimental Science." Owing to the want of financial support the publication ceased in 1843, after 10 volumes had been issued. It is a valuable work of reference, relating more especially to the progress of electricity. Many of the articles were written by Sturgeon.

[1842.] "A Familiar Explication of the Theory and Practice of Electro-Gilding and Electro-Silvering"—"By means of which any person may be enabled to gild or silver coins, medallions, trinkets, ornaments, or household ornaments such as spoons, knives and forks, candlesticks, plates, covers, or any other metallic article whatever at a very trifling cost, and with the utmost facility. The instructions for gilding and silvering are preceded by descriptions of a great variety of voltaic batteries, and all that is necessary to be understood by the operator in the theory of voltaic electricity."

Digitized by Google

[1842.] "Lecture on Electricity," delivered before the Royal Victoria Gallery, Manchester, during the session 1841-2. Dedicated to the proprietors and annual members of the Royal Victoria Gallery. He thanks them for their constant attendance, and although each lecture was delivered twice in the same day, the attendance was unremitting and in increased numbers. To the annual members he was particularly indebted for their unanimous vote of thanks at their last meeting in the lecture room.

[1843.] "A Course of Twelve Lectures on Galvanism," illustrated with upwards of 100 engravings of experiments and apparatus. In the preface, which is dated Institute of Natural and Experimental Science, Manchester, July 20, 1843, Sturgeon says that the lectures are arranged nearly in the same order in which he was in the habit of delivering them.

[1843.] "The Annals of Philosophical Discovery and Monthly Reporter of the Progress of Practical Science." According to the advertisement "This periodical, to commence July 1, 1843, price 1s. per month, will represent clearly and intelligibly the most important Philosophical Discoveries and the Application of Science to the Arts, without loading the description of them with those redundant Introductions, Intercurrences, and Terminations with which many scientific papers are frequently clogged, and which in most journals occupy many pages to which a great diversity of matter, of much higher interest to the generality of readers, might be introduced. The work will be printed on good paper and with a neat type, and, where necessary, engravings for explanation will be inserted." Six numbers were issued; the last, December, 1843.

[1843.] "The Whole Galvanoplastik Art or Method of forming Electrotypes of Medallions, Coins, Statuary, Bronzes, Ornaments, &c." Translated from the German of Prof. Jacobi. With a large folding lithographic plate. "This is the best work hitherto published on this interesting branch of the fine arts, and ought to be in the hands of every family in the kingdom who have any desire to become acquainted with these beautiful productions of voltaic electricity."

[1843.] "Sturgeon's Edition of Barlowe's Treatise on Magnetism." With Notes by the Editor. This is a reprint of a rare old work, "William Barlowe's Magneticall Aduertisements; or, Diverse Pertinent Observations and Approved Experiments concerning the Nature and Property of the Loadstone, very pleasant for knowledge and most needful in practice of travelling, or for the framing of instruments fit for travellers both by sea and land." "I am not aware," says Sturgeon in the preface, "that any apology will be required for undertaking to resuscitate a good old scientific book, otherwise entirely lost to the greater part of the present generation of philosophers."

[1846.] "Practical Instructions for the Protection of Persons and Property from the Effects of Lightning."

[1850.] "Scientific Researches, Experimental and Theoretical, in Electricity, Magnetism, Galvanism, Electro-Magnetism, and Electro-Chemistry." With copper plates. Published by subscription by Thomas Crompton, Bury, Lancashire. Quarto of 563 pages; 19 plates by Bradshaw and Blacklock, Manchester. This was Sturgeon's last work, and collects all his published papers. It is described as an ornament of provincial printing. John Just, of Bury, his old friend, was particularly instrumental in having it printed in Bury. Two other editions appeared, that of 1852 being published by Longmans and Co., to ensure a wider circulation. This appeared after his death, and the profits arising were given to his widow.

The Experimental Researches contain a list of about fifty original Papers, the titles of which were printed in *The Electrician* of July 5, 1884. Dr. Joule has examined Sturgeon's claims as a scientific discoverer, and in a letter* says that after sifting Sturgeon's claims to the utmost he finds without doubt that he was the originator of the electro-magnet, of the improved electromagnetic machine with a commutator, and of the first rotary electromagnetic engine. The first electromagnet was described in the *Proceedings* of the Society of Arts for 1825. It consisted (*see* Figs. 1 and 2) of a bent iron rod, about a foot long and one inch in diameter, varnished over and wound with a single layer of stout uncovered copper wire, the ends of which dip into mercury cups. The circuit was completed through a wire, *d*, which could be lifted out of the cup Z when it was desired to break the circuit. A weight, *y*, of about 9lb.

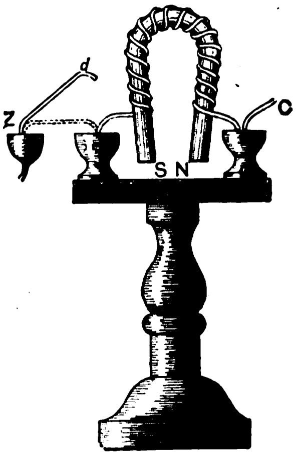

Fig. 1.

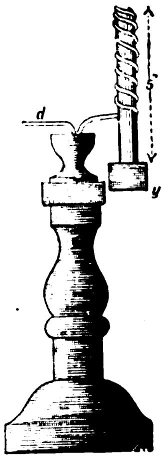

Fig. 2.

could be supported. An arrangement for magnetising straight bars is shown in Fig. 3.* The use of amalgamated zinc plates for primary batteries was due to Sturgeon. His researches on thermo-magnetism and magnetism of homogeneous bodies are of value. By means of 500 kite observations he added to our knowledge of atmospheric electricity, and he has shown how ships might best be protected from lightning; but his inventions in electro-magnetism must be always regarded as the most important part of his work. Sturgeon's claims and history

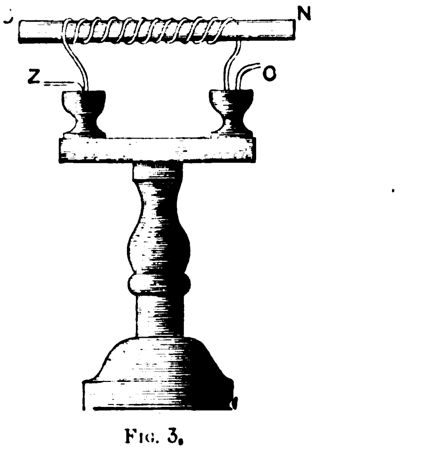

Fig. 3.

are well summarised on a marble tablet in the parish church of Kirkby Lonsdale:—

IN MEMORY OF

WILLIAM STURGEON,

Who was born at Whittingham, A.D. 1783, and buried at Prestwich, Lancashire, on the 8th day of December, 1850.

He was the son of parents in humble life, and served as a private in the Royal Artillery for nearly 20 years. After completing his term of service he successfully devoted himself to the study of the Physical Sciences.

With powers of originality and industry rarely equalled, besides contributing numerous works to the Scientific Literature of his country, he was the discoverer of

The Soft Iron Electromagnet,
The Amalgamated Zinc Battery,
The Electromagnetic Coil Machine, and
The Reciprocating Magnetic Electrical Machine—

Inventions of the highest value, and which along with many others he freely gave to the world.

His name will be perpetuated as long as the Sciences he cherished continue to exist.

This is the only public memorial of a man to whom electrical science owes so much. It is to be hoped that before long the Royal Artillery Institution may possess (as suggested by Major Murdoch), a portrait of Sturgeon, and that in some public building or institution of Manchester we may have a suitable memorial of his connection with the city as a teacher, author and investigator.* W. W. HALDANE GEE.

THE ELECTRIC ARC.

BY HERTHA AYRTON.

(Continued from page 421.)

Before proceeding to compare my equation (4) (p. 420, *The Electrician*, July 26th) connecting P.D., current and length of arc with the equations found by previous experimenters, it seems to me that it may be useful to others if I give, in Table IX., a list of the actual values that were used in plotting the curves in Fig. 33 (page 419, *The Electrician*, July 26th) :—

Table IX.—*Means of the Experimental Results used in Plotting the Curves in Fig. 33.*

The numbers in italics refer to hissing arcs.

The numbers in any one column in Table X. are the results of the experiments carried out in a single day with this particular length of arc, and, although the carbons did not require to be changed each day, sometimes a new positive and sometimes a new negative carbon had to be inserted, so that, on the whole, about three different positive carbons and three different negative carbons were used in obtaining the numbers given in Table X.

Many people have from time to time experimented on the arc with the object of discovering the true relationship connecting the P.D. between the carbons, the current flowing, the length of the arc, and its resistance; and, in order to compare their results with my equation (4) (p. 420, *The Electrician*, July 26th), I have prepared the following abstract of their work and of the deductions drawn by the authors. Such an abstract appeared to me to be particularly desirable, as some of the writers on the arc appear to have misunderstood the results obtained by others.

ABSTRACT OF THE PRINCIPAL PAPERS BEARING ON THE PHYSICS OF THE ARC.

The first quantitative experiments were, I believe, made by Edlund* in 1867. In spite of the disadvantages under which he laboured—for he had no dynamo, and at that time there were no recognised units of current, P.D., or resistance—Edlund discovered one of the fundamental conditions of the arc, namely, that with a *constant current* the apparent resistance is equal to a constant resistance, plus a resistance which varies directly with the length of the arc.

Edlund's method of experimenting was as follows: he used a battery to send a current through an arc of definite length, then, putting out the arc and pressing the carbons tightly together, he measured the distance by which he had to separate the plates in a copper voltameter so as to bring the current to the same value as before. Doing this for various lengths of arc he found that, *as long as the current was kept constant*, the length of the copper voltameter which represented the arc could be expressed by a constant length plus a length which varied directly with that of the arc.

Hence, putting his result in the form of an equation, he found out that

$$r = a + b\,l,$$

* During the last few years considerable interest has been aroused in the history of Sturgeon. For this we have chiefly to thank Prof. S. P. Thompson, who has written a short biography of Sturgeon, and in his work on the "Electromagnet," has shown that Sturgeon was undoubtedly the inventor of the soft iron electromagnet, and that the claims of Arago could not be maintained. This recently has been made perfectly clear by Mr. Ernest Boistel, who has examined all the records of the work of Arago. A number of gentlemen in Manchester have been most assiduous in collecting information relating to Sturgeon. Among these I must especially mention Mr. C. Roeder. Many of the facts ascertained have been embodied in this article, but the complete biography of Sturgeon has yet to be written.

* Poggendorff's *Annalen*, 1867, Vol. CXXXI., p. 586.

where r is the apparent resistance of the arc, l its length, and a and b constants *for a constant current.*

When, however, the current was varied, he found that a and b both diminished as the current increased, so that the apparent resistance of the arc for a given length was the smaller the greater the current. The numbers which he obtained justified him, he considered, in concluding that a varied inversely as the current, but those for b were too small to enable him to arrive at the law connecting b with the current.

Edlund started his experiments with the idea that there was a back E.M.F. in the arc caused by the disintegration of the carbon particles, and therefore, having obtained several values of a and b with different currents, he calculated the back E.M.F. in the arc when each of those currents was flowing.

From these calculations he concluded that the *back E.M.F. in the arc had a constant value equal to that of about 23 Bunsen's cells for all the currents he used*, and that *the true resistance of the arc was directly proportional to its length, increasing, however, as the current decreased.*

He next considered the question theoretically, and gave what he regarded as a proof that the back E.M.F. in the arc must be independent of the current, and also that the work performed in the arc by the current was proportional to the current as long as the E.M.F. of the battery remained constant.

He then made a new series of experiments to determine whether the back E.M.F. depended upon the E.M.F. of the battery used to produce the current, and decided that it did not.

Edlund's next series of experiments* was undertaken to find out whether the back E.M.F. was constant with smaller currents than had been used in the first series. The deflections produced by the currents in the tangent galvanometer used were not published in this case, as they had been before, but Edlund considered that his results showed that, in the case of small currents, the back E.M.F. *diminished* as the current was decreased. He used copper, brass, and silver pole points for these experiments, as well as carbon.

Edlund's third series of experiments† was very striking. He found that when an arc was produced with a somewhat large current between *carbon* poles the arc continued for a short time after the circuit was broken, so that, if the circuit were closed again fairly quickly after the break had been made, the arc was not put out. But, on the other hand, when *silver* poles were used the arc did not continue for even one-eightieth of a second after the circuit was broken.

From this he concluded that if carbon poles were used, and if immediately after opening the circuit the carbons were switched on to a galvanometer, a momentary current would be sent by the arc through the galvanometer, and the existence of the back E.M.F. in the arc thus made certain. A series of experiments carried out in this way with and without a battery being switched with the arc into the galvanometer circuit, led Edlund to conclude that the back E.M.F. existing in the arc *after* the main circuit had been broken could not be less than that of from 10 to 15 Bunsen's cells. Further, from the momentary current being increased when the negative carbon was warmed by a Bunsen's burner, and not diminished as might have been expected had the back E.M.F. been a thermo-electric one (set up by the positive carbon being hotter than the negative), he concluded that the back E.M.F. in the arc was *not* due to thermo-electric action.

Mr. Schwendler,‡ during the course of an investigation on "The Electric Light," carried out in 1878 for the Board of Directors of the East Indian Railway Company, gave the following conclusions in a *précis* of his report :—

"There appears to be no doubt that an appreciable E.M.F. in the arc is established, which acts in opposition to the E.M.F. of the dynamo machine. This E.M.F. of the arc *increases* with the current passing through the arc. The resistance of the arc for constant length is also a function of the current passing through it, *i.e.*, the resistance of the arc *decreases* with the current (*see* the following table)."

Current in webers.	Resistance of the arc in Siemens units.	E.M.F. of the arc in volts.
28·81	0·91	2·02
23·87	1·72	1·91
16·27	1·97	1·86

Mr. Schwendler goes on to say that he considers it highly probable that the resistance of an arc of constant length is inversely proportional to the current. No details are given in this *précis* regarding the way in which the E.M.F. of the arc was measured.

In a Paper on "The Resistance of the Electric Arc" * Profs. Ayrton and Perry in 1882 described experiments made with Grove's cells to test the accuracy of Mr. Schwendler's conclusion, and they found that, when carbons 0·24in. in diameter were used and the length of the arc kept constant, the current could be varied from about 5 to 15 amperes without much change being produced in the P.D. between the carbons. They also used a Brush machine to produce an arc up to 1·25in. in length, and gave as the equation connecting V, the P.D. between the carbons in volts, and a, the length of the arc *in inches*

$$V = 63 + 55\,a - 63 \times 10^{-10a},$$

and this equation they regarded as being true for currents between 5·5 and 10·4 amperes with the carbons employed.

In 1883 Frölich† desired to find out whether Edlund's equation $r = a + b\,l$ were true for the larger currents that could be obtained with dynamos, and, in order to obtain an equation connecting the P.D. between the carbons with the length of the arc, he used the results of experiments made by various people, at various times, for the purpose of testing the dynamos constructed by Messrs. Siemens and Halske. In the table given in his Paper the P.D. corresponding with different currents for the same length of arc showed wide variations, yet he took it for granted that the P.D. was really independent of the current and so he deduced the equation

$$V = a + b\,l$$

as the relation that would connect the P.D. between the carbons with the length of the arc, *whatever the current*, if there were no errors of observation in the experiments.

He even found what he considered to be the numerical values of a and b, and so he put his equation connecting V. the P.D. in volts between the carbons for an arc l millimetres in length produced by *any current from 1 to 100 amperes* in the form

$$V = 39 + 1{\cdot}8\,l$$

From this formula he calculated what he considered ought to have been the P.Ds. for the various currents and lengths of arc in the 47 measurements, the results of which he quoted; and the differences between the results given by his formula and by experiment he put down to errors of experiment.

By dividing by A, the current in amperes, Frölich's formula became

$$r = \frac{39}{A} + \frac{1{\cdot}8\,l}{A},$$

and this he considered was the formula which gave r the apparent resistance in ohms of an arc l millimetres long produced by a current of A amperes. He used the latter formula to calculate a table of 273 resistances of arcs, varying from 0mm. to 20mm. in length, and produced by currents of 1, 5, 10, 15, &c., up to 100 amperes; but no experiments are adduced giving results agreeing with his calculated values.

He then proceeded to inquire if his "newly-discovered facts" threw any light upon the question whether there was a back E.M.F. in the arc or merely a contact resistance, and he concluded that either explanation was consistent with the facts provided that the cross-section of the arc was directly proportional to the current, which he considered likely.

Multiplying both sides of his equation by A, he obtained the following equation giving W, the power in watts expended in the arc:—

$$W = (a + b\,l)\,A;$$

and, therefore, he concluded that the power expended in an arc of fixed length was directly proportional to the current.

In 1885 Peukert* published an account of some experiments he had made with constant currents and varying lengths of arc, for the purpose, as he said, of "eliminating one of the three possible variables, P.D. current, and length of arc." In order to avoid having a crater, and thus complicating the measurement of the length of the arc, which was made by projecting the distance between the carbons on a millimetre scale, he had the carbons filed flat before each experiment, and the determination made before the carbons had had time to burn away much.

Having obtained the P.Ds. needed to send currents of 10, 15, 20, 25 and 30 amperes through various lengths of arc, he plotted curves connecting resistance and length of arc for each current, and found that they were all straight lines, so that Edlund's equation,

$$r = a + b\,l,$$

was proved true for large as well as for small currents.

Peukert, like Edlund, found that a varied inversely as the current, but b, Peukert pointed out, diminished more quickly than the current increased. This latter fact, he thought, was partly explained by the air surrounding the arc becoming very hot when the current was large, and so acting itself as a conductor.

He considered the question of a back E.M.F. in the arc, and showed that the mean value of $A\,a$ was about 35 volts. He considered, however, that an E.M.F. of this large value could not be set up by the disintegration of the carbon as Edlund had supposed, and that a back E.M.F., if so produced, ought to increase with the current. He also considered the possibility of the back E.M.F. being produced thermo-electrically, or by the combination of the carbon points with the hydrogen gas liberated by decomposition of vapour in the air, but both these suggestions he rejected also.

Peukert finally concluded that most probably the resistance of the arc was really composed of two parts, one that of the arc proper, while the other, and much the larger part, was a mechanical, or contact, resistance between the arc and the carbon. And he added that a certain minimum P.D. being necessary to maintain an arc, which fact had been adduced as a proof of the existence of a back E.M.F. might arise from a certain P.D. being necessary to tear off the carbon which formed the conducting medium between the two carbons.

In 1885 Von Lang† endeavoured to measure the *true* resistance of the arc, as distinguished from the *apparent* resistance, which alone had been determined by previous experimenters. To do this he used a battery, $B_1\,B_2$ (Fig. 40), to produce two arcs, L_1 and L_2, in series, each ⅓mm. long, formed with carbons 5mm. in diameter; and between the arcs there was placed a resistance, R R. A point, A, in the resistance was then found, having the same potential as B, the middle point of the battery. Then, since these two points of the quadrilateral were at the same potential, the parallel resistance of the two halves of the quadrilateral between A and B could be measured with a Wheatstone's bridge, exactly as if there were no E.M.Fs. in the quadrilateral.

This resistance Von Lang found to be 1·82 ohms, and therefore the resistance right round the quadrilateral was 4 × 1·82, or 7·28 ohms. Next the arcs were replaced with equal resistances of such a value that the current flowing round the quadrilateral, as measured by the ammeter, C, was the same as before, viz., 4·32 amperes. The parallel resistance between the points A and B was now found to be 6·29 ohms, and consequently the resistance right round the quadrilateral was 4 × 6·29, or 25·16 ohms. Hence the E.M.F. of the battery $B_1\,B_2$ was 4·32 × 25·16, or 108·7 volts. And, as the quadrilateral had a resistance of 7·28 ohms when the two arcs were in the circuit, a P.D. of 4·32 × 7·28, or 31·4 volts, must have been employed in sending the current of 4·32 amperes round this quadrilateral as far as its resistance was concerned. Consequently a P.D. of 108·7 − 31·4, or 77·3 volts, must have been employed in overcoming the back E.M.F. of the two arcs, or the back E.M.F. of each arc, was 38·6 volts.

* *Zeitschrift für Elektrotechnik*, 1885, Vol. III., p. 111.
† *Wiener Akad.*, 1885, Bd. 91, § 844, and *Centralblatt für Electrotechnik*, 1885, Vol. VII., p. 443.

Shortly afterwards Edlund* summed up the results obtained by himself, Frölich, Peukert, and Von Lang, and proceeded to consider Peukert's view that the term a in the equation $r = a + b\,l$ represented a resistance of transition at the surface of contact of the electrodes and the arc. Edlund concluded that, since the value of the back E.M.F. of the arc—39 volts—obtained by Von Lang's method, which depended on the measurement of the true resistance of the arc, did not differ much from either the values obtained by himself, 41·97 volts, or by Frölich, 39 volts, or by Peukert, 35 volts, it followed that *there was no resistance of transition in the voltaic arc, and that, therefore, the entire diminution of the strength of the current which resulted from the production of the arc light was caused by the resistance of the arc $b\,l$ and by the E.M.F. contained in it.*

In 1886 Messrs. Cross and Shepard† made experiments with both silent and hissing arcs to determine whether the apparent resistance of the "whistling" arc was a linear function of the length for a constant current, as had been shown by Edlund and others for a silent arc. They used currents varying from 3·27 to 10·04 amperes, and lengths of arc from 0·25/32 to 16/32 of an inch, and found that for a given current the resis-

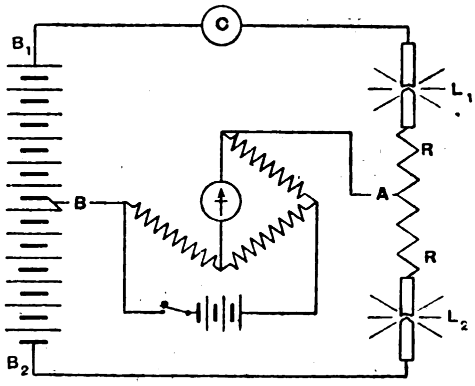

Fig. 40.

tance of the whistling arc could also be represented by a straight line in terms of the current, but that this line was steeper than that representing the resistance of a silent arc for the same current.

Without expressing any opinion as to the existence of an inverse E.M.F. in the arc, they gave this name, for convenience, to the product $A\,a$, where A was the current and a was given by the resistance equation

$$r = a + b\,l,$$

and they found by experiment that both with silent and with whistling arcs this product $A\,a$ diminished as the current increased, having a mean value of 39·33 volts for a silent and 14·98 volts for a whistling arc. With very long arcs, however, and with long arcs in which metallic salts are volatilised, the apparent resistance tended to become abnormally small.

Next they experimented with an inverted arc, and although it was much less steady than before, the results obtained were practically the same.

The arc having been restored to its original position, they surrounded the positive carbon with a deep cup-shaped shield of fire-clay in order to retain the heat, and found that this increased the inverse E.M.F. both for silent and for whistling arcs, as well as the length of the arc at which whistling occurred for each particular current. On the other hand, b, the coefficient of l, was diminished.

Cooling the positive carbon with a water jacket, on the other hand, caused the E.M.F. to fall to 11·7 volts for a silent and to 5·6 for a whistling arc.

Finally, a few experiments were made on an arc under a pressure of 4in. of mercury. The equation $r = a + b\,l$ still held, but the arc hissed for all the lengths and currents tried, and the lines connecting resistance and length were less steep than those for hissing arcs under normal pressure for the same currents respectively.

Arons* found the *true* resistance of the arc by placing it with the battery, producing it in one arm of a Wheatstone's bridge. One of the diagonals of the bridge contained the stationary coil of a dynamometer, while the other contained the secondary coil of an induction apparatus. The three arms of the bridge were adjusted until this inductor sent no current through the stationary coil of the dynamometer, as proved by there being no deflection of the movable coil of the dynamometer, which was traversed by an independent alternating current produced by an auxiliary induction apparatus.

Next the arc was short-circuited and a resistance put in its place of such a value that, without making any alteration in the resistances of the other three arms of the bridge, no current was sent through the dynamometer-diagonal of the bridge by the secondary coil of the first inductor which formed the other diagonal. Under these circumstances this added resistance was equal to that of the arc. With a current of 3·4 amperes, Arons found the true resistance of the arc to be 2·1 ohms, and therefore the back E.M.F. 40·6 volts, while with a current of 4·1 amperes he found the true resistance of the arc to be 1·6 ohms, and therefore the back E.M.F. 39·6 volts. The length of the arc is not stated in his Paper.

In the same year Von Lang† repeated his method illustrated in Fig. 40, and now found 37 volts as the value of the back E.M.F. between carbons. This method he also employed with electrodes of other materials, and he found that when they were both composed of one of the following substances, arranged in the order indicated—platinum, nickel, iron, copper, zinc, silver, cadmium—the back E.M F. on the arc fell steadily from about 27 volts for the platinum electrodes to about 10 for those of cadmium.

Von Lang expressed V, the P.D. between the carbons, as

$$V = a + b\,l\,A\,;$$

but a, the back E.M.F., is, for no one of the pairs of electrodes used, given with a probable error of less than + or − 3 per cent., and in some cases it is as high as + or − 34 per cent.

Uppenborn,‡ in 1888, found from experiments with a constant current of 7·7 amperes, producing an arc with 10mm. carbons, that

$$V = a + b\,l,$$

where l was the length of the arc. a, however, in this equation varied from 35·4 to 45·4, and b from 1·74 to 3·2.

When the current was increased he found that *a increased*, while *b diminished*. a, he considered might be replaced, by $x + y\,A$, where A was the current and x and y depended on the carbons. He concluded that, since a increased both for increase of current as well as for increase in section of the arc, the effects were probably due to surface resistance rather than to a back E.M.F.

Dubs,§ in 1889, found that if two carbon plates were placed one above the other with a distance of 1mm. between them, and a blowpipe flame was directed on the lower so as to carry carbon particles to the upper, a galvanometer connected with the plates showed a weak current flowing against the blast. Also that if a carbon plate were heated on a oxyhydrogen flame and laid on a cold carbon plate, a current flowed from the cold to the hot plate. With copper plates the effect was less, and was *nil* with iron. Dubs regarded the effect as analogous with the back E.M.F. in the arc, and considered that that depended, at any rate in part, on the mechanical action of the current.

In 1892 Stenger‖ sought for evidence of a back E.M.F. in the arc thus: A shunt-dynamo sent a current through an arc, 5 accumulators and a tangent galvanometer in series. The accumulators were joined up so as to oppose the current, and the needle of the galvanometer was pressed against a stop so that it was not deflected by the dynamo current, but could move freely in the opposite direction. On short-circuiting the shunt-dynamo the conduction of the arc lasted long enough for the accumulators to send a current and produce a deflection of over 90deg. in the galvanometer; but, when the experiment was repeated with the accumulators removed from the circuit, a deflection of only about ¾deg. occurred, produced by the spring of the stop. Hence any back E.M.F. in the arc either ceased with the main current, or was very small compared with 10 volts.

In a Paper read before the British Association in 1892, Prof. Silvanus Thompson* gave an approximate formula connecting V, the P.D. in volts between the carbons, l, the length of the arc in millimetres, and A, the current in amperes, viz. :—

$$V = a + \frac{b\,l}{A},$$

where the constant a, however, had to vary between 35 and 39 volts and the constant b between 8 and 18. The constant part of the voltage which was independent of the current for an invariable length was sometimes called the apparent back E.M.F., and, although Dr. Thompson did not affirm that there was an actual back E.M.F., the arc, he considered, acted as though it were the seat of a back E.M.F.

He described his experiments, made with an auxiliary exploring carbon, which showed that the drop of potential in the arc itself was small, and that the main drop was at the positive carbon. The latter, he considered, was accounted for by the volatilisation of the carbon at the crater, and that this idea was confirmed by Capt. Abney's discovery that the brilliancy of the same quality of carbon per square centimetre was a constant. Mr. Crookes's experiments, which showed that the flaming discharges produced by very high-pressure very short-period alternating currents were endothermic flames of nitrogen and oxygen, had led him to try whether the combination of nitrogen and oxygen produced by the high temperature of the arc had anything to do with the E.M.F. observed there. To test this he had surrounded the arc with a glass tube, and introduced successively oxygen, nitrogen, carbon dioxide, hydrogen, &c., but with a normal arc taking 10 amperes not one volt difference in the P.D. was observed. When chlorine or carbon monoxide surrounded the arc the positive carbon was flattened over the end, and the end of the negative became a very obtuse cone, while with hydro-carbon gas the crater was very deep; and, lastly, when the arc was formed in oxygen the carbons burnt away very rapidly. The gases had to be introduced quietly, since blowing on an arc in ordinary air Dr. Thompson found raised the P.D. to 75 volts.

In August, 1893, just before Prof. Ayrton read his Paper at Chicago on the arc, Messrs. Duncan, Rowland and Todd† published an account of the effects they had obtained on producing an arc under pressure and in a vacuum. They began their Paper by stating that the two causes alleged for the back E.M.F. in the arc—the vaporisation of the positive pole and the thermo-electric effect produced by the carbon vapour in contact with the unequally heated carbons—must both be operative; but that the first must cease to exist directly the main current ceased to flow, and could not therefore be detected even immediately after the circuit was broken, while they considered it must be possible to detect evidence of the latter for a short time after the main current had been stopped.

The first part of the back E.M.F., viz., that due to the volatilisation of the carbon, they considered must be a constant a, while the second part must be a function of the current and the length of the arc. From these considerations they suggested that the complete equation connecting P.D., current, and length of arc should be

$$V = a + f(l)\,f(A) + b\,f'(l)\,f'(A),$$

where V was the P.D. between the carbons, l the length of the arc, and A the current.

* *The Electrician*, Vol. XXIX., August 26, 1892, p. 460.
† *Electrical Engineer* of New York, August 2, 1893, p. 99.

Digitized by Google

They next called attention to the fact that the P.D. between the carbons diminished as the current increased, and gave the results of experiments supporting this. The following they suggested as an explanation of the phenomenon. If V be the P.D. between the carbons, *a* the *constant* back E.M.F. due to volatilisation of the carbon, and *a'* the back E.M.F. due to thermo-electric action,

$$A = \frac{V - a - a'}{b\,l};$$

$$\therefore \quad V = a + a' + b\,l\,A.$$

Now, *a'* diminishes with increases of the current, since the temperature of the negative carbon increases while that of the positive remains constant. Hence V diminishes as A increases.

Keeping the current constant at six amperes, and the arc of a fixed length, they found that, starting with the atmospheric pressure, V increased as the pressure was increased, but at a slower rate. When, on the other hand, the pressure of the surrounding air was reduced below that of the atmosphere, V also increased except in the case of the $\frac{1}{16}$th-inch arc, when V diminished on reducing the pressure. This exceptional result, however, arose probably from the arc hissing. Hence, for a given current and length of silent arc, V has a minimum value for atmospheric pressure. The increase of V as the pressure was reduced below that of the atmosphere they considered was caused by an increase of *a'*, for they say that *a*, the constant counter E.M.F., was probably lower in a vacuum, and the positive carbon not so hot, but the negative carbon seemed to cool proportionately faster than the positive.

The counter E.M.F., they concluded, increased apparently with the pressure above one atmosphere, while the ohmic resistance of the arc did not greatly change. As regards the formula their experiments showed that *a* varied with *l* for each pressure employed, and they failed to arrive at any exact law connecting V, *l* and A, even for one pressure, the equation that most nearly fitted their results being, they thought,

$$V = a + \frac{b\,l}{A^{0.7}},$$

but this, they remarked, was only approximately correct.

The latest measurement of the *true* resistance of the arc was made by Mr. Julius Frith* with the Wheatstone's bridge seen in Fig. 41. Two of its arms, P, Q, consisted of the two halves of a stretched platinoid wire each having a resistance of 5·35 ohms. The third arm was composed of a battery of 26 accumulators, E, which, together with a shunt dynamo D_1, sent a current through a resistance, R_1, an ammeter C and the arc X in series, the arc being 2mm., formed with carbons 11mm. in diameter. The fourth arm consisted of a shunt dynamo, D_2 exactly similar to D_1, only at rest, together with resistances R_2 and R_3 and a coil L, whose self-induction could be varied by moving an iron core.

The resistances of D_1 and D_2 were each 0·04 ohm; of R_1 and R_2, each 8 ohms; of E, 0·25 ohm; and of R_3 0·3 ohm.

Before closing the switch S the speed of the dynamo D_1 and the length of the arc were varied until the potential of the points A and B were equal, as tested by the voltmeter V, which, by means of the switch K, could be connected either across the accumulators E or the arc X.

An alternator D_3 sent an alternating current through a wire, any two points of which could be tapped to supply the alternator P.D. to the bridge, and after closing the switch S the resistance of R_3 and the self-induction of L were varied until the sound in the telephone T became a minimum, the condenser M inserted in the telephone circuit cutting off from the telephone any direct current effect that might be caused by want of perfect equalisation of the potentials of the points A and B.

The best results were obtained with R_3, having a resistance of about 0·6 ohm and an alternating P.D. of 5 volts supplied to the bridge. This makes the resistance of the arc about 0·6 ohm, which, together with the readings of the ammeter C and the voltmeter V, give the back E.M.F. in the arc as 39 volts.

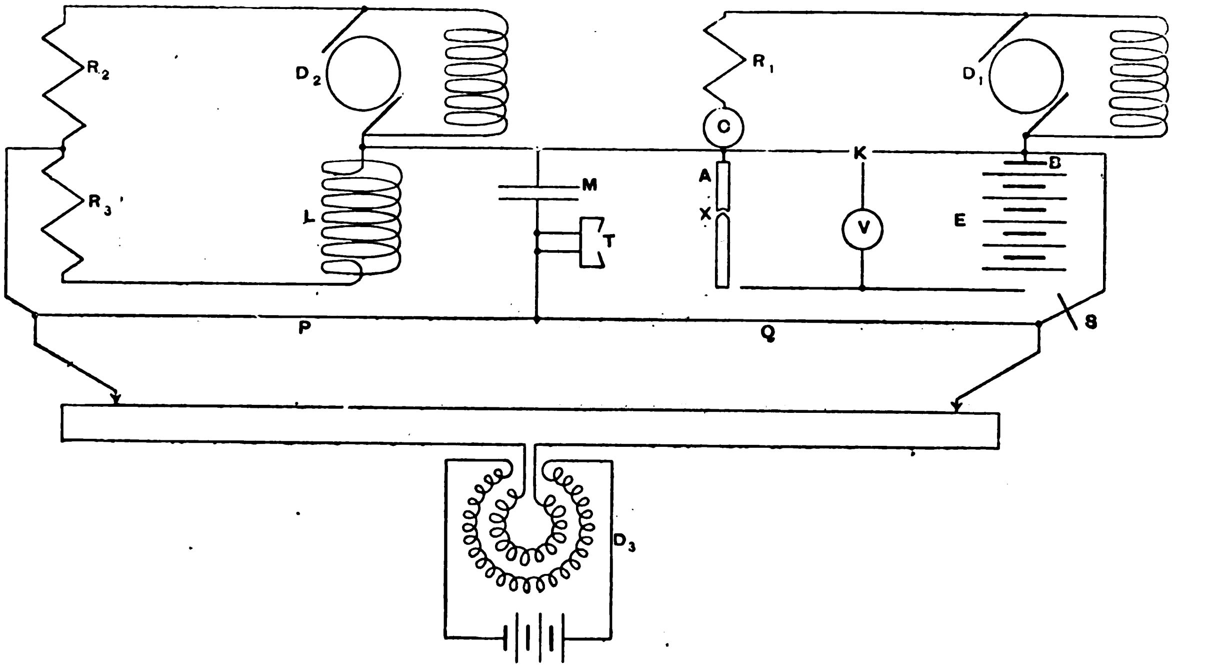

Fig. 41.

Other methods of testing were employed by Mr. Frith, and results were obtained agreeing with the above.

Mr. Wilson* has recently experimented on the electric arc under considerable atmospheric pressures. As the pressure was increased, and the current kept constant, he found that the apparent resistance of the arc increased. When the pressure had been raised to five atmospheres the temperature of the crater had fallen, while at 20 atmospheres the brillancy of the crater fell to a dull red colour. Diminishing the pressure, on the contrary, increased the brightness.

Mr. Wilson therefore concludes "the temperature of the crater, like that of the filament in an incandescent lamp, depends on how much it is cooled by the surrounding atmosphere, and not on its being the temperature at which the vapour of carbon has the same pressure as the surrounding atmosphere." Hence the temperature of the crater is *not* that of boiling carbon as has been asserted.

SPECIAL NOTICE.

With this week's number of "THE ELECTRICIAN" is issued a Fine STEEL PLATE PORTRAIT of WILLIAM STURGEON. This Supplement is issued gratis, and complaints of non-receipt should be sent immediately to the Publisher.

NOW READY.—Vol. XXXIV. of "THE ELECTRICIAN," bound in strong cloth. Price 12s. 6d., post free 13s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

MAGNETIC UNITS.

In summing up the correspondence which for some weeks has been actively pursued in our columns, we are impressed by the sense that these letters, many of them from men the best qualified to judge (at least so far as Great Britain is concerned) as to the practical value of a system of magnetic units, have done much to clear the air of cobwebs. Whatever, therefore, the British Association, or its Committee on Electrical Standards, may decide to adopt or to leave aside, they cannot be ignorant of the strong drift of opinion which has made itself known in these letters.

For the last four years the question of fixing a "practical" set of magnetic units, or at least of finding names for them, has been in the air. At the rather informal Electrical Congress at Frankfort in 1891, the American delegates presented a proposition suggesting certain names and definitions, which, however, were barely considered. The opinion there seemed to be, though no formal vote was recorded, that no other units than those of the C.G.S. system were required. Again, at the Chicago Congress, the subject was brought up, only to be again put off. Subsequently the American Institute of Electrical Engineers took independent action, and definitely proposed a number of practical units, based on the C.G.S. system; and to them they assigned names derived from those of notable men in magnetic science: WEBER, GAUSS, GILBERT and OERSTED. The name of GAUSS seems to have a special attraction for unit coiners. It was used already in different senses by Prof. FLEMING and by Mr. HEAVISIDE; and had been used again in a different sense, so far back as 1884, by Prof. SILVANUS THOMPSON. The Committee of the American Institute are quite frank as to their aims. They did not propose any units other than those of the C.G.S. system. What they did propose was names for units which exist. So far their idea was simple. But when one comes to consider the names themselves the selection does not seem a particularly happy one. For the unit of magnetic flux (which is one C.G.S. "line") they proposed the name *weber*. So far so good. But for that of the magneto-motive force they proposed the name

Digitized by Google

gilbert, and for the unit of field and of flux density (in air or metal) the name of *gauss*. It would have been distinctly better to have reversed the use of these. The word *volt* is of one syllable, the word *ampere* of two; so that the two magnetic names that correspond should preferably be of one syllable and two syllables respectively. Like the word *volt*, which easily lends itself to the allied distributive *voltage*, so the word *gauss*, a one syllable word, lends itself to become the distributive *gaussage*, while the word *gilbert* does not. Just as an electric circuit of unit resistance requires an electromotive force of one *volt* to produce one *ampere*, so in a magnetic circuit of unit reluctance it requires one *gauss* to produce one *weber*. That is, if we use *gauss* for the unit of magnetomotive force, as now proposed by Prof. Lodge. If we mistake not, the term *gauss* has also already been so used at the Central Institution for some time.

Quite other are the radical proposals of Mr. Oliver Heaviside. He wants, once and for all, to get rid of the difficulty that crops up in the ever-recurring symbol 4π—a heritage of the fate that caused our present electromagnetic system to be based on the old notion of surface units of magnetism, and the law of inverse squares as applied to poles at a distance. Instead of defining the unit of magnetism as that which, at the distance of one centimetre (in air) repels its fellow pole with a force of one dyne, he would define it as that which (in air) repels it with a force of 4π dynes. He would then draw one line for each such unit of magnetism, which would consequently be greater than our present C.G.S. unit by $\sqrt{4\pi}$, or 3·544 times. This gets rid of the 4π difficulty by stuffing it into a new corner. But Mr. Heaviside does not stop here. He proposes to perform a like transformation upon our electric units, with the result that he brings us face to face with a new ohm equal to 1·257 of the old ohm, a new ampere equal to 2·24 of the old ampere, and a new volt equal to 3·544 times the old volt. The practical man, who has at last grown familiar with ohms and amperes and volts, holds up his hands in horror. Had it been proposed to make both ampere and volt ten times their present value, so as to bring them into agreement with the respective C.G.S. units of current and pressure, he would have protested vehemently. But to "rationalize" them by the use of such irrational multipliers—No: it shall not, must not, cannot be!

And yet we are not sure that Mr. Heaviside is not right, even though it be a case of Heaviside *contra mundum*. Some day, when point poles, and surface units, and action-at-a-distance shall have vanished into the limbo of mediæval absurdities, and when electricians have learned to think of *action in the medium*, we shall wonder how that foolish old B.A. Committee of 1862, and that feeble International Congress of 1881 ever blundered into the C.G.S. system. And then we shall turn to our Heaviside, who tried to save us from ourselves. But in a world of practical issues, of commercial interests, and of men of business, not even for the sake of the more enlightened generation that will follow, can we afford to contemplate such revolutionary measures. To recommend them piecemeal, even by the inspired voice of a British Association Committee, would only have the effect of indefinitely shelving more pressing, though moderate, reforms. We therefore, and with a genuine regret, set them aside as too good for this unheroic age.

But though we set aside these drastic proposals, we are by no means of opinion that absolutely nothing ought to be done. The correspondence in our columns is a proof that, while there exists a strong feeling against tampering with old units, or coining needless new ones, there apparently is some need for names to fit those actually in use. The fact that one dynamo designer uses "kilo-lines" and "mega-lines," that another uses "thoms," and a third "kapps," in describing the amount of magnetic flux in a magnetic circuit may perhaps be taken as a sign that a name is wanted. Incidentally it also tends to show that the thing for which a name is most wanted by designers of dynamos and motors is not **H** or **B**, but the total flux or total induction **N**. While objecting to the wholesale creation of fantastic names, and units of more than doubtful utility, we are ready to admit that someting like a case has been established for recognising by a definite designation the unit of magnetic flux. As to the magnitude of the unit itself, the only question that can arise is whether we shall take the C.G.S. unit itself—namely, one (magnetic) *line*, or some multiple of it, such as 10^8, to correspond with the *volt*. The suggestion of Dr. Sumpner to call 10^8 *lines* a *volt-line*, the advantages and disadvantages of which we discussed last week, has this further objection: it gives to the word *volt* a new and purely numerical meaning. Better, far, to use "megaline" as the term for a million *lines*; for if the unit is fixed so large as 10^8 we shall occasionally require to talk of a *centi-micro volt-line* when we mean simply one magnetic *line*. Why not take the *line* itself as unit—whether it is called the *weber* or simply the *line* is a detail—and apply the usual prefixes for multiples?

Our correspondents who are engineers are also nearly agreed amongst themselves in another point—namely, that as unit of magnetomotive force the *ampere-turn* should be taken as the unit. The $4\pi/10$ factor must needs come in somewhere, either here or in the definition of the third quantity, which, whether considered as a reluctance or a permeance, comes in as the ratio of the two others. Engineers who have to deal with construction prefer to take *ampere turns* simply. As Mr. Snell puts it, both the *ampere* and the *turn* are shop quantities; and the relation between *ampere-turns* and the resulting flux-density is in practice habitually taken off from a graphic curve that embodies the result of pure experiment. In that case no new name is wanted for the unit, as the *ampere-turn* is itself the name. To call it one *gauss* does not help matters; the name is only wanted in case something more complex than the ampere-turn, and needing therefore a short designation, is decided upon.

If the *line* and the *ampere-turn* are thus fixed, the third unit—whether regarded as reluctance or permeance—is fixed in magnitude, being the ratio of the other two. It can be defined materially as a property of a definite prism of air, the permeance or reluctance of which will be a standard, just as the material *ohm* is a standard both for resistance and conductance. There will be time enough to devise a name for it when we shall have decided on its magnitude.

Amongst Prof. Lodge's suggestions is one for a unit of magnetomotive force per-unit-of-length, or *gauss-fall*. Again, we remark that the only desirable unit is that which already exists—namely, the C.G.S. unit of fall of magnetic potential per centimetre; in other words, the familiar **H**, measured by the mechanical force it exerts on a unit pole. Our trans-Atlantic friends, in their eagerness for progress, have suggested that the same unit that serves for flux-density will serve for this, because of the accident that in air they are numerically (in the C.G.S. system) alike. But one is the cause, and the other the effect. Though we may express by similar numbers the effect **B** of applying a cause **H**, it does not follow that the quantities are of the same order, or should be expressed in terms of the same unit. Unfortunately we have dropped into applying the notion of lines per square centimetre to express both the effect and the cause. Let us now discriminate; but before we proceed to christen the unit let us

Digitized by Google

think when, by whom, and how often, such a unit is likely to be used. Hardly one of our correspondents has so much as noticed the existence of this quantity. Obviously it is little used by them. If the hydrographer to the Admiralty is anxious to give up his ridiculous foot-grain-second unit, and yearns to express the values of H at different points of the earth's surface in C.G.S. measure, by all means encourage him to do so, even at the price of inventing a new name for it. Thenceforth the value of H at London will be 0·18 *somethings*.

Ours is no mere policy of *laissez-faire*. The criticisms we have passed from time to time on the proposals of our American friends, and of our correspondents, have been written in no spirit of captious carping. We are above everything desirous that our progress should be solid; and that therefore we must be willing to proceed slowly, and on the lines which the actual working pioneers in the ranks of the profession indicate as lines of utility. And thereafter, to whatever is once settled we must doggedly adhere. There must be no more idea of changing the *henry* than of altering the *ampere* or the *ohm*. It may not be much use now that we have got it; but there it is, and we will not consent to tinker with either the unit or its name. New units, if and when they are really wanted. New names only if old ones do not already exist. But no jerry-building of fancy units, and no tinkering.

MOLECULAR ELECTRICITY.

The logical outcome of FARADAY's law of electrolysis is that every active atom in an electrolyte has a definite quantity of electrical charge—a sort of natural unit, or a simple multiple of such unit—invariably associated with it, and that fractions of such unit charge are not known. These are precisely the kind of data which in the sphere of matter led DALTON to his atomic theory of its constitution; and in accordance with this analogy there have been no lack of suggestions that perhaps electricity is atomic too,—indeed it may have been noticed that leaders like MAXWELL and HELMHOLTZ have, though with some reserve, coined and employed the extraordinary and impressive phrase "one molecule of electricity." The unit charge is now better known by the more cautious appellation, given to it by Dr. JOHNSTONE STONEY (who indeed was one of the first to emphasise this deduction from FARADAY'S laws) of an "*electron*," and these electrons are evidently going to play a great part in the theoretical developments of the immediate future.

"The hypothesis with which we [now] start is that electrical and chemical forces are identical; that electrification is a manifestation of unsatisfied chemical affinities, and that chemical union is a binding together of oppositely-charged atoms or groups of atoms." Such are the luminous words of Prof. POYNTING in our issue of to-day, and no doubt they express the view to which modern thought has been tending for some years past. Every electrostatic field has long been known to consist of a state of etherial strain which may conveniently be mapped and expressed as consisting of a region of lines of force each of which begins at one piece of matter and ends at another. The material atoms being known to be themselves intrinsically charged, it is natural to picture every line of force as beginning at an electro-positive atom and ending at an electro-negative one. Further, if these atoms are put into a state of locomotion, as in electrolysis they certainly are, it is natural to picture the phenomena of the current as due to, or at least accompanied by, a travelling of these lines of force through space. Recent researches in electro-convection in gases have led Prof. CHATTOCK, Prof. J. J. THOMSON and others to regard gas conduction as an essentially similar process, and the latter philosopher has further supposed that probably metallic conduction is but a modification of the same sort of process as goes on during electrolytic conduction, although at first sight the two processes appear very different. We find plenty of indications in these directions in Prof. LODGE'S "Modern Views of Electricity," especially in its second and fuller edition published in 1892; while in Prof. J. J. THOMSON'S "Recent Researches in Electricity" the attempt is made to work out nearly all the phenomena of electricity and magnetism on such an electrolytic basis.

In the articles of Prof. POYNTING, which we feel sure will be generally welcome, this attempt is made in a still more vivid and simple manner, and we think no one can fail to be impressed with the beauty and essential simplicity of a great part of what he has brought before us. It is not a very ambitious attempt: it does not seek to give us a hydro-dynamical theory of the ether and the universe, as the recent work of Dr. LARMOR does; it does not seek to find any *ultimate* explanation of electric and magnetic facts, it leaves fundamental dynamics alone, and by assuming some of the best-known facts of electrostatics without at present seeking to account for them, it presses them into the service of explaining most other electrical phenomena. Prof. POYNTING does not assume that electrons can exist detached from matter: every line of force with him is, as it were, an elastic connection between two atoms of matter, and only differs from a gravitational line in that it possesses an opposite sign at its two ends, —an exceedingly momentous difference, however. We are asked to picture these atoms mixing and separating, interchanging their lines of force according to the law of electrostatics; and we are asked to think of these same lines as flashing along laterally with the speed of light, and thereby giving rise to the phenomena which we associate with the term "electric current." The main idea is, of course, not new, but some of the details of its working out are very suggestive. Perhaps it may be useful if we rapidly call attention to a few of the less entirely satisfactory features of Prof. POYNTING'S treatment, leaving any detailed study of the matter for more leisurely consideration.

Our author seems to object to the statement that two gold leaves repel each other. Now undoubtedly, if attention is concentrated on the electrostatic field, as is most profitable at the present time, it is necessary to think of the lines of force as reaching from each leaf to the outer case, and the two leaves are truly pulled apart. That is the proximate explanation. But, then, how is this pull, or any pull, to be explained in a more ultimate manner? Can there really be any force in Nature other than a *vis a tergo?* Do we not expect that when the ultimate hydro-dynamical or etherial theory is fully fledged it will be found that by vortices or by some such mechanism the leaves are really being pressed apart? If so, then denunciation of language expressive of repulsion should be guarded as having only a convenient practical and immediate application.

Again, Prof. POYNTING complains that the earth is usually treated as if it were a return circuit in telegraphy, whereas it is really a "parallel outgoing circuit for the opposite charge, enabling the two electricities to travel in company and to join each other." Now, admitting not only the truth but the desirability of emphasising this mode of regarding the facts, we demur to its being denied that the earth is a return circuit, for we would ask Prof. POYNTING whether in any ordinary return circuit the same thing cannot be equally well said. It is well to explain the true meaning of the idea of a "return circuit" in terms of the particular hypothesis or

Digitized by Google

proximate explanation under consideration, but it does not assist matters to discriminate between the earth and a metallic wire return-circuit. The phrase "return circuit" undoubtedly savours of a unitary, or "one-fluid" view of electrification, while Prof. Poynting has boldly launched himself on a dual view—every line of force has two ends, and they usually both travel in opposite directions at rates nearly equal; hence it is that the phrase "return circuit" no doubt strikes him as altogether unsatisfactory and obsolete.

His remarks concerning the figure which comes first among his illustrations are very luminous, and he might have added to their force by calling attention to what could happen, on any of the three alternative hypotheses mentioned, if the discharge key were only depressed momentarily, so as to leave a large fraction of the charge still in the condenser. There can be no question but that the lateral flashing out of the lines of electrostatic strain—the running of their ends along the wires, and the running of their energy into the wires—is the only satisfactory mode of regarding the phenomena of the discharge-current from this point of view: and a certainly helpful, though as certainly a very partial and incomplete, mode of regarding an electric current it is. The magnetic concomitants of the current are assumed but not explained, by Prof. Poynting; they are supposed to follow somehow from a lateral transfer of the electrostatic line, and, indeed, to be the condition without which no such transfer can occur; but the mechanism whereby the lines travel, and whereby the magnetic effects are produced, is not touched upon.

Hence we say that the theory is by no means an ambitious or fundamental attempt to grapple with the difficulties of the ether; it is merely a timely and helpful representation, suited to people accustomed to dealing with chemical and electrostatic forces, of a mode of extending their ideas to embrace a whole range of fresh territory, which otherwise might seem foreign and inaccessible. No doubt the main difficulty in the complete identification of chemical and electrical forces is that connected with the mode of combination known as "molecular," in opposition to atomic. So long as we attend to a simple electrolyte everything goes swimmingly, but when the ions have to deliver up their charges at an electrode, unite with each other, and rise as gas, it is difficult in the first place to suppose that they have really parted with their charges, and it is still more difficult to see why, if they have so dis-electrified themselves, they are still able to combine with each other. That H and Cl can hang together seems natural enough, but that H should also be able to combine with H, and Cl with Cl, is a puzzling fact. Some have suspected that the mode of combination in these cases was more analogous to gravitation or cohesion than to chemical affinity or electrostatic force, and that for this reason molecular compounds were insusceptible to electric influence. It may be so; but that is not the way Prof. Poynting regards it. He boldly surmises that although the charge of a monad atom cannot be gradually diminished or altered in magnitude, yet it may be reversed—he even conjectures a kind of mechanism for such reversal;—and granting the fact of reversals, so that half the atoms become positively and half negatively charged under the stress of the action going on at an electrode, there is, of course, no further difficulty about their entering into combination with each other just as if the two ingredients were entirely different elements at opposite ends of the chemical scale. Perhaps this is the simplest way out of the difficulty, but it raises questions as to whether a negatively-charged hydrogen atom is really hydrogen, or whether a positively-charged oxygen atom is to be supposed to have the normal properties of oxygen. Perhaps the solution of this sort of question lies in the statement that no single atoms can have the properties of the substance in bulk, and that the substance as we know it *always* consists of these oppositely-charged atoms in equal numbers. But then why is such an elementary substance not an electrolyte, and why can we never coax the constituents of such an elementary molecule to travel as ions towards opposite electrodes? For answer we have to call attention to the fact that such a substance *is* a dielectric, and that when rarified its properties become more or less nearly electrolytic.

Prof. Poynting is the first to admit that his treatment of these matters is tentative and unsatisfactory, but nevertheless the whole mode of treatment adopted in his article is one eminently suited to be helpful towards forming some kind of consistent mental image of a part of what is going on in that mysterious commonplace, an electric current; and whatever may be the ultimate fate of the hypothesis as he has presented it, there can be no doubt that it will repay much careful thought, and there is always the possibility that it may be fertile in results.

REVIEWS.

Polyphase Electric Currents. By Prof. S. P. Thompson, D.Sc., F.R.S., &c. Finsbury Technical Manuals. (E. and F. N. Spon.)

In the autumn of 1894 Prof. Silvanus Thompson delivered a course of four lectures at the Finsbury Technical College on Polyphase Currents, and it is certain that the interest shown in those lectures was as much a surprise to the lecturer as it must have been to others. Not only was the lecture room packed to an uncomfortable degree, but among those present might be seen many to whom studentship had long been past, men who in various departments of engineering were themselves masters. Prof. Thompson, in fact, as is his wont, had hit the psychological moment. "Magnetism in rotation" was the question of the time; coherent literature on the subject, with the exception of Mr. Kapp's "Electric Transmission of Energy," then just published, did not exist, though many valuable scraps lay buried up and down in cosmopolitan journals and magazines. It is fitting, then, that these lectures, expanded, in some respects remodelled, and amplified with valuable historical and index matter, should find a more permanent form in the shape of the present volume. It is right also that the reader should realise that this is the origin of the work now under notice, for a form which is natural to a lecture or series of lectures is not necessarily the best for a treatise, and probably this will be the first feeling in the mind of the reader. To be really appreciated the work wants reading carefully at least twice, bearing in mind the second time what there is after as well as before. Thus the first chapter, after a little preliminary matter deals at once with the principle of alternate-current generators for producing alternating currents of two and three phases, and the second chapter with the method of combining these differently-phased currents, without any hint or reason being given of why such apparently complicated means should be adopted of producing or transmitting power, and this procedure goes on till Chapter IX. is reached. This commences: "Alternate-current motors may be classified as follows:" Then follows a classification, and a chapter which with a little expansion would have formed a true groundwork for this book. Few electrical engineers who have not studied this question in detail grasp why it is that multiphase-current motors have in recent years eclipsed every other form of alternating motors. It really has nothing whatever to do with rotating magnetic fields. The reason may be thus stated briefly: An alternating motor is like a continuous-current motor made up of two parts, a part (the armature) having a small amount of self-induction, a part (the field magnet) having a large amount of self-induction. With alternating E.M.F.'s the phase of the current depends on the ratio between

Digitized by Google

the self-induction and the resistance, and hence if we supply the magnetising circuit and the armature circuit from one source of E.M.F. the phases of armature current and magnetic field are different and the result small; if we supply them from sources differing in phase, the phases of the magnetic field and armature current may be made the same and develope power. That really is the underlying reason for polyphase currents for motive power. Motors embodying these ideas have recently made the strides they have for a mechanical reason. English engineers would never have accomplished what has been done, probably American engineers never would; it needed a nation of watchmakers—the Swiss—for no other training would ever have made it possible to make motors with "rotors," as Dr. Thompson names them, 12in. in diameter, running at 1,200 or 1,500 revolutions per minute with a clearance of one-fiftieth of an inch. And yet in these two facts lies the secret of alternating-current motors as of to-day: (1) supply phases which shall bring field and armature currents into phase, (2) magnetic resistance reduced as near zero as possible so that the electro-kinetic momentum of the magnetic field circuit is as small as possible. How far the small clearance necessary will eventually prove a drawback in practical work it is too early yet to decide.

Returning, however, to the book before us, and assuming that the reader has read the ninth chapter, and has examined the interesting examples of modern polyphase generators in the first chapter, Chapter II. deals with the methods of combining circuits carrying alternate currents of different phases, the most important part being that which discusses the economy of copper, with various combinations of phases and circuits. This part is perhaps not quite as clear as it might be made, but the principles which govern the various cases are gone into and elucidated. Then follows a discussion of the method of geometrically combining alternating magnetic fields, and showing how the conception of a rotating magnetic field arises. Chapter III. deals with the properties of rotating fields. Chapter IV., on the early development of the polyphase motor, is important. Dr. Thompson, as is well known, is in his element as the historian; but in view of the importance the historical aspect of this question is likely to assume, this chapter requires a little careful discrimination. Bailey's motor of 1879 was undoubtedly a true lineal ancestor of the modern induction motor, but among all the other early motors described there are none that really bring us any nearer to the modern motor until we come to Ferraris', whose first publication was in March, 1888, and Tesla's American application for a patent for an induction motor dating November, 1887, and published in May, 1888. The motor of Borel (1887) would work if the rotor were laminated to prevent eddy currents, and therefore cannot be classed with modern induction motors, whilst the three-phase motor of Coerper (Helios Company), 1887, is a synchronous motor, and was intended to work with a magnetic field magnetised in one direction. So that in Bailey, Ferraris and Tesla we have all the early history of the modern polyphase induction motor, as distinguished from the polyphase synchronous motor.

Chapter V. deals with the structure of polyphase motors, and gives a description of some experiments by Brown, in 1890, on the results of different forms of notches and windings for inducing and induced windings. It was the result of these experiments which determined Brown in the use of hole-wound inducing and induced windings, a practice which, notwithstanding, is likely to be abandoned in the near future in favour of wholly or partially open notches in order to diminish the local self-induction of the windings. Chapter VI. is on the elementary theory of polyphase motors, the treatment being based on that of Kapp, the substance of this chapter was given in *The Electrician*, November 23, 1894, whilst Chapter VII. gives an analytical theory, based on a memoir of M. Potier in *Bulletin* de la Société Internationale des Electriciens, of which it is only necessary to say that whilst accurate for the case it deals with, viz., a motor without magnetic leakage, for any purpose of design it is useless.

The next chapter (VIII.) introduces us to "monophase" motors, and we may congratulate the author on having escaped from that theory, apparently originated by one of Brown's patents, which considers, as Mr. Kapp has put it, "that self-induction in the armature (*rotor*) is an essential condition of its working," notwithstanding that he himself gives the test of a motor in which the power factor reaches 93 per cent., a result indicating a remarkable absence of self-induction.* This is not the place to give a rational theory of monophase motors, but surely the mathematicians are running riot when a motor receiving its energy from a single oscillating field is explained (!) by two imaginary magnetic fields revolving in opposite directions. Chapter IX. we have already alluded to. Chapter X. gives a useful and practical idea of polyphase transformers for transforming pressure, phase and period by stationary and revolving transformers, in which we see that pressure and phase may be transformed by stationary or revolving transformers, but period by the latter only. Measurement of polyphase power is briefly dealt with in Chapter XI., whilst Chapter XII. ("Notes on Design") is of a practical nature, but it really tells us more of what has been done than serves to guide us forward. Chapter XIII., on the mechanical performance of polyphase motors, with examples from modern practice, is admirable. The last chapter deals with the distribution of polyphase currents from central stations, of which there are some half-a-dozen examples in practice. Following these is an Appendix, "Bibliography of Polyphase Currents and Rotatory Field Motors," of which it is sufficient to say that if the book contained nothing else it would be worth possessing. Appendix II., "Schedule of some British Patents bearing on Polyphase and Alternate-Current Motors," is helpful, but is hardly sufficiently complete to be trustworthy by itself.

"I would like to say that I have no great love for alternating currents," said Prof. Thompson in 1888,† but, like so many others fighting against the stormy waves of the single-phase current, he has been drawn in by the vortex motion of the rotary field, and is a convert. The author of this book has rendered service to engineers and students before, in his "Dynamo-Electric Machinery" and his "Electromagnet," and not less in the present work. It contains a mass of research condensed into readable form, and if the theories are conventional rather than real, they are at least the current theories, and if in parts the work has the appearance of haste, we may forgive it in that it is absolutely up to date.

MOLECULAR ELECTRICITY.

BY J. H. POYNTING, SC.D., F.R.S.

In a Paper in *The Electrician* of October 13, 1893, after some criticism of the "wheelwork" hypothesis of electro-magnetic actions, I concluded by saying that I believed that "the time has hardly come for ultimate mechanical construction, and that at present progress is more likely to be made if we are content with an electromagnetic explanation—if we merely carry down to the molecules and their interspaces the electric and magnetic relations which we find between large masses, and round large circuits and leave the ether out of account."

I propose to follow out this idea, to see where it leads us, and what difficulties we have to face. The idea is in many minds, and we have examples of its use in the papers of Prof. J. J. Thomson and in the articles by Mr. Chattock in Dr. Lodge's "Modern Views of Electricity" and the *Philosophical Magazine.* The fullest account yet published is, I think, in Prof Thomson's "Recent Researches," Chapter I, but there are some difficulties not there brought to the front. I believe there will be some advantage in a new statement, starting with the very alphabet of the subject, and following it up by full examination of the consequences. In the belief that some way may yet be found to remove the difficulties, and that even now it gives us a valuable picture of some electrical actions, I venture here on a full description of the shape it has taken in my own mind.

The hypothesis with which we start is that electrical and chemical forces are identical; that electrification is a manifestation of unsatisfied chemical affinities, and that chemical union is a binding together of oppositely-charged atoms or groups of atoms.

Before descending to the atoms, let us briefly consider what we observe on the large scale coming within the range of experiment. The foundation stone of our electrical knowledge is the experimental result that the two kinds of charge are always found in equal amounts with opposite or neutralising mechanical properties, and that they always face each other on the two sides of the insulating matter between them. We add to this the idea that the energy of the charges accompanies some kind of strain—alteration, perhaps, of atomic or molecular configuration—in the insulating medium. The two charges, in fact, always join hands through the dielectric; or, putting the same idea in another form, the charges are manifestations on the bounding surface of a state of strain within the dielectric, somewhat as hydrostatic pressure is a manifestation on the surface of the vessel containing a liquid of a strain to which the liquid is subjected. When this idea of strain was enunciated by Faraday and rendered precise by Maxwell we had only the variation of inductive capacity to support it. But now the double refraction of dielectrics in the field discovered by Kerr, and the wave phenomena discovered by Hertz, give as near a positive proof of the existence of the electric strain as we can ever hope to get.

In a system at rest the electric strain ends at the surface of a conductor and the electric stress or pull on the surface $2\pi\sigma^2/K$ per sq. cm. is resisted on the other side of the surface by ordinary mechanical stress accompanying ordinary mechanical strain in the matter of the conductor. Some day, perhaps, we may be able to manufacture a hypothesis identifying mechanical and electrical strain; but at present we are obliged to separate them and think of them as different in kind, since mechanical strain in moving off or dying away does not give rise to the magnetic or chemical actions which characterise the moving off or dying away of electric strain.

We symbolise the relative value of the strain at different points of the field by unit tubes of induction each beginning at $+1$ and ending at -1 of electrification. The strain varies inversely as the cross-section of a tube, and we regard the reciprocal of the specific inductive capacity $1/K$ as a kind of modulus of electric elasticity. Though tubes of induction give us a better description of the imagined physical condition of the dielectric, it is easier to use lines of induction, one for each tube, when we have to draw figures.

These ideas of duality of charge, and of strain between them, which we owe to Faraday and Maxwell, though now accepted by everyone, have hardly yet so saturated our minds that we instinctively use them in every case. We still too often find descriptions of elementary phenomena which entirely leave them out of account. Like charges are still described as repelling each other, as when the gold leaves of an electroscope diverge, without a hint that the apparent repulsion is really a pull on each body along the lines of induction stretching out to the opposite charges induced on the surrounding conductors. The earth is still looked upon as a big conductor which will hold any reasonable amount of electricity without showing signs of it, and we speak of discharging a body into it instead of saying that the opposite charge is usually on the earth or the walls of the room in which we work, and that when a conducting bridge is made the two charges can come together so that the inductive strain is relieved, and its energy is dissipated. Or to take another example where common language and thought lag behind the more precise ideas given to us by science: the earth, as the "return" circuit of a telegraph wire, is still described as a reservoir from which, say, + can be pumped up at the sending end and into which it can be emptied out at the receiving end, just as if a telegraph wire corresponded to a pipe running above a water reservoir with a pump at one end and a spout at the other. Sometimes even we find the process described as if the charge going to earth at the receiving end knew its way back through the earth to the particular battery from which it started. Whereas the earth is really not a return circuit at all, but a parallel out-going circuit for the opposite charge, enabling the two electrifications to travel in company and to face each other—one on the wire, the other on the earth—whether the earth be the bare ground under an aerial line or the sheath of a cable in the bed of the ocean.

This travelling of opposite charges to meet each other is to be regarded, I am convinced, as the essential electrical part of the ordinary current. The lines of induction connecting the charges sweep through the air or other surrounding insulator, and this motion of the induction, or travelling onwards of the electric strain, is accompanied by—indeed, is rendered possible by—the magnetic induction which surrounds the conducting wire. The only case of current without motion of charge is the gradual cessation of charge in an imperfectly insulating condenser. Here the charges simply die away *in situ*—their strain decays and their energy is dissipated; and as there is no motion of induction there is no magnetic field.

To realise how ordinary current may be described in terms of motion of lines of induction let us suppose that, instead of the more usual dynamo or battery as source, we have a charged condenser with the − terminal to earth and the + terminal insulated, but capable of connection by a key with a wire earthed at the farther end. Up to the instant when the key is put down the two charges are almost entirely in the condenser, joining hands in the dielectric between the plates. The still prevalent mode of describing the current on contact at the key is equivalent to supposing that, as soon as the + found a door open to it, it freed itself from the embrace of its −, put its hands in its pockets, ran along the wire, setting all the neighbouring magnetic machinery spinning as it rushed past, and finally plunged into the earth at the farther end. The −, no longer kept up or "bound" by the +, sank into the earth at the condenser end, and both were lost in that vast electrical abyss, the globe.

But let us see what is really implied in the process of discharge if we keep to our fundamental principle that + and −

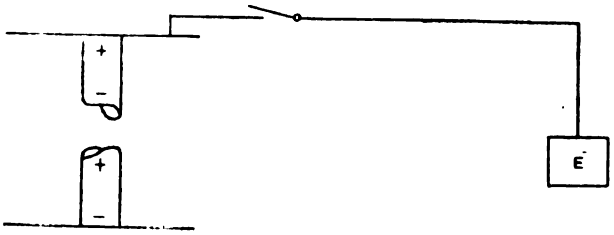

FIG. 1.

always have induction tubes or lines between them. Let us try the various suppositions which seem open to us, and let us first imagine as a possibility that the charges are able to start on their travels by breaking their induction tubes somewhere in the dielectric between the condenser plates, as in Fig. 1. At the broken ends we must have opposite charges (just as in a broken magnet we have opposite poles), for a charge is the end on matter of an induction tube. If each + unit setting out along the wire drags the broken half of its tube after it into the wire, we shall have on the whole equal + and − travelling in the same direction along the wire and no external magnetic effect. Indeed, as soon as the leading + has drawn its piece of tube completely into the wire there does not appear to be any reason against the union of the + and − at opposite ends of the piece, and then nothing need occur in or around the rest of the wire. But as we have magnetic and other effects in and around the whole length of wire, and everything is against the passage of + and − in the same direction, we are bound to reject this supposition of breaking tubes. As another supposition let us imagine the tubes as remaining in the dielectric of the condenser but growing longer where they stand, and as it were pushing their end charges before them, the one through the wire, the other into the earth. But this will leave the tubes still in full strength in the dielectric, and when the disturbance in the wire has died away the condenser will still be fully charged, which is absurdly at variance with experience. The only possible supposition still left to us is that the tubes of induction spread out sideways from the dielectric of the condenser into the

Digitized by Google

surrounding air, connecting the + and − charges as these move respectively along the wire and the earth. The induction—that is, the condition we call electric strain—is propagated by the working machinery from point to point through the air, and the motion of this machinery is manifested as magnetic induction, symbolised by lines of magnetic force which form closed circuits round the wire. We cannot explain this mode of transfer, but the mechanical models of Maxwell and Lodge and Fitzgerald help us to accept it as possible.

We must now introduce the idea that conductors are dielectrics—of a special kind, no doubt—admitting of electric strain, though allowing it to decay rapidly and dissipating the energy they receive in the form of heat. We may take as a helpful analogue to this behaviour of a conductor the behaviour of a liquid under ordinary elastic shear strain. A liquid can receive shear strain just as much as a solid, but the strain decays, that is, rapidly loses its energy, and the lost energy is transformed to heat. But the still undecayed strain remaining at any instant gives a tangential resistance to shear, which we recognise as viscous resistance to the motion of one layer relative to the next. So in a conductor such as a wire, electric strain may be produced and electric energy may be taken in; but the strain decays almost as fast as it is received and the energy is changed to heat. The E.M.F. along the wire is proportional to the strain remaining still undecayed at any instant, and this E.M.F. corresponds to the elastic stress—the viscous resistance—of a sheared liquid.

In the case of the condenser which we are considering, as the induction tubes spread out from it their end portions are continually moving sideways into the wire, and to a less extent into the earth, and there melting away and dissipating their energy as heat. New ends are continually being formed at the junctions of the decayed and undecayed portions, and these ends travel further and further along the circuit until the tubes are entirely propagated into the conductors, when the discharge is complete.

A full account of this mode of regarding current, and the relations involved between electric and magnetic induction, with an attempt to show that it applies to the voltaic circuit as well as to such a circuit as we have here considered, was given in the *Philosophical Transactions* for 1885. Prof. J. J. Thomson has modified and elaborated the theory in the *Philosophical Magazine* for March, 1891, and in his "Recent Researches in Electricity and Magnetism," Chapter I. The full theory shows that if we assume that the magnetomotive force round a closed curve is equal to $4\pi \times$ number of electric tubes cutting the curve per second, then the magnetic field is accounted for. If, then, we make the electric tubes move so as to account for the right electrical quantities, the magnetic properties will follow as a matter of course, and we may therefore concentrate our attention on the electric tubes, as we have done in the preceding account of one case of current. I have given this case at length, by way of introduction, to show that here at least the only way in which we can think consistently of current in a wire is in terms of motion of + and of −, and of tubes of electric induction connecting them and sweeping through the surrounding medium into the wire. We shall see later how such tubes may be supposed to be furnished by the recombinations which occur in the voltaic circuit, and I have no doubt that in all other cases of current the same kind of explanation may be given.

There is another reason, perhaps, for giving here the foregoing account of a condenser discharge, in that the hypothesis which I am going to describe may not inaptly be termed a condenser hypothesis of electricity. The properties which we find in condensers will be carried down to the molecules, which we shall suppose to be small condensers with equally and oppositely-charged atoms forming the two plates. Of course, this will not explain electricity. It is a purely electrical hypothesis, and it shifts all responsibility of further explanation on to the shoulders of whatever atomic hypothesis we adopt, just as Weber's magnetic hypothesis gives no explanation of magnetism, but assumes the molecules to be ready-made magnets, and leaves to them the burden of accounting for themselves.

We are naturally led to make the hypothesis from the consideration of the chemical action of current. When a voltameter is included in a circuit a perfectly definite quantity of electrolyte is decomposed for a given number of induction tubes moving sideways into it. All parts of the liquid between anode and cathode are concerned in what goes on, and there are two opposite processions of ions. This is all experimental fact. Representing the action atomically we may obtain the net result by the old Grotthus chain method of picturing the process, and each atom set free requires the supply of a definite constant amount of electric induction, calculable if we know the number of atoms per gramme of the substance.

Let us now consider how electrolysis may occur. We shall imagine a somewhat abstract kind of electrolyte, one consisting of molecules, each with a pair of atoms, an abstraction, a simplification, which we shall have to discard later. To account for the exact chemical equivalence of electrolysis in different cases we shall have to suppose each atom to be supplied with the same amount of electric induction, to have the same minute fraction of an induction tube starting from it if it is of one kind, ending on it if it is of the other kind. To

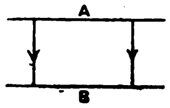

Fig. 2.

bring the induction up to a thinkable size we must choose a new unit—I suppose millions of billions of times less than the ordinary unit, and it will be convenient to picture the atom as supplied with two, four, or some such small number of tubes in terms of this new unit.

Here, then, is our molecule, represented in Fig. 2. A is the positive and B the negative atom. The molecule is, in fact, a little condenser with fixed charges, and the distance between A and B is usually small compared with their distances from neighbouring molecules. But we must suppose that in general A and B do not come in contact, perhaps through motion of vibration or of rotation relative to their centre of gravity.

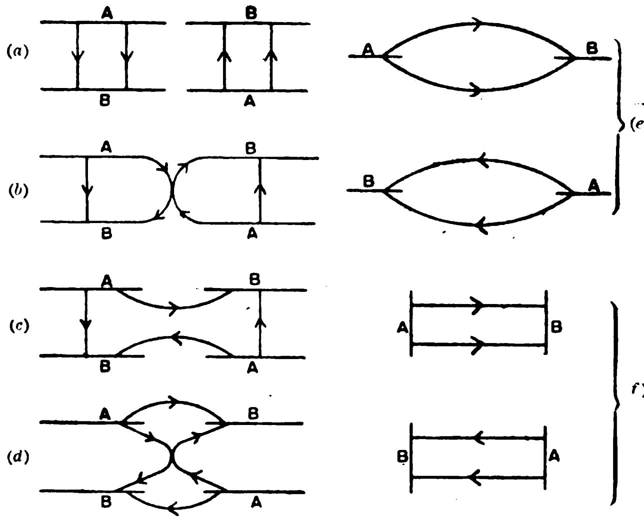

Fig. 3.

There is therefore persistence or conservation of their tubes. The electrical attractions symbolised by these tubes are absolutely identical with the chemical attractions of the molecules and the electrical energy they contain with the chemical energy of the molecule. It is easy to see, however, that two molecules colliding may become connected, and form a more complex group, and may even effect an exchange of atoms.

Thus, in Fig. 3, (*a*) to (*f*) represent successive stages in the process of exchange. Just as, when two condensers are brought near with their tubes of induction running in opposite directions, cross-connections are formed by the coalescence and neutralisation of parts of the tubes, so here we may suppose that in a molecular collision the tubes straying out coalesce, and the parts which run in opposite directions destroy each other. In (*c*) we have a more complex molecular group. If the process is

Digitized by Google

continued we may arrive at (*f*), which gives the original molecular configuration but with exchange of partners. If we are ever to attempt an electrical hypothesis of elasticity and cohesion we shall have to suppose that straying of tubes is always going on in solids and liquids, and that complex groups like (*c*) are always being formed, so that each molecule is attached to its surroundings. In gases not in an electric field the molecules may be regarded as much more self-contained.

(*To be continued.*)

ISLE OF MAN ELECTRIC TRAMWAYS.

Snaefell, the highest of the mountains in the Isle of Man, has recently been brought into closer communication with the civilised world by an electric tramway ascending nearly to its summit from Laxey, the nearest town. The summit of this mountain is destitute of every residence, excepting a small hotel recently built; there is, therefore, no ordinary inducement, as was the case with the Douglas-Laxey electric tramway, to carry a tramway to it. Neither is there any great attractiveness in the bleak rugged mountain-mound itself, for its height is far below that of its Icelandic namesake, and but little exceeds 2,000ft. There is, however, ample justification for the construction of nearly five miles of double railway up this mountain, in the fact that tourists regard the magnificent view which is to be obtained from the summit as unequalled by that from any point in the world at the same moderate altitude. Hitherto the ascent has been made with difficulty, or at considerable expense, by few people; but now that the electric cars are running, a stream of some 600 to 1,000 visitors per day is maintained.

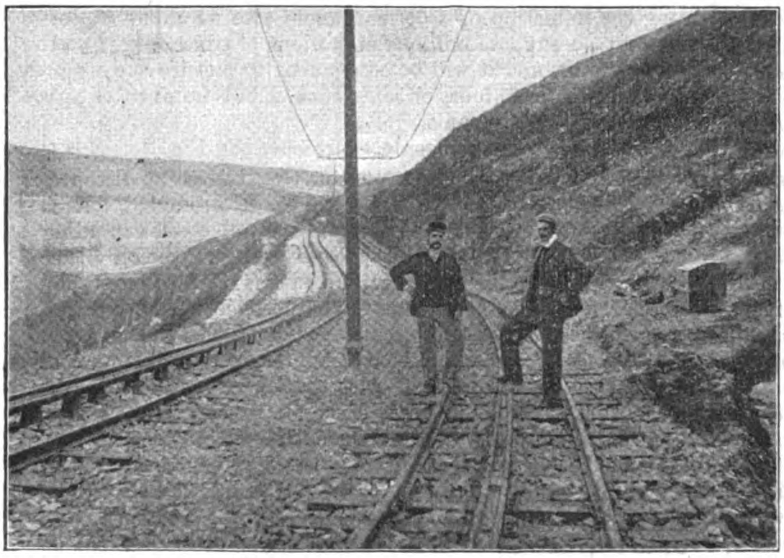

FIG. 1.—Snaefell Mountain Electric Tramway. View from steep gradient, on cutting, showing level track beyond.

The summit of Snaefell is 1,860ft. above the level of the Laxey terminus of the line, and the mountain terminus is but 44ft. below the highest point. The route chosen, after careful surveys by Messrs. McKerrow and Fell, extends along a length of 4·7 miles of track. There is, therefore, a ruling gradient of about 1 in 12. The surface of the mountain side is extensively covered with thick peat, and below this there is a deep stratum of contorted shale, the stratification principally being at a steep angle or else vertical. The greater part of the track, which is doubled throughout, lies in cuttings in the face of the steep sides of the mountain; and an immense number of curves, of from 10 to 20 chains in radius, have been rendered necessary. There is, however, no tunnelling, and the view is uninterrupted. Heavy retaining walls are occasionally erected against the cuttings; the advisability of these being emphasised by the fact that the recent storm swept away a portion of the outer part of the track, at a place where it had not been so retained.

The general character of the track may be seen in the accompanying illustration, Fig. 1. This view shows in the foreground a steep gradient, with a dead level portion (apparently, however, on a reverse incline) in the distance. Both tracks are laid with three rails, spiked to cross sleepers of creosoted timber. The two outer rails are of the Vignoles flat-bottom type, of steel weighing 50lb. per yard. They are fished at the joints in the usual manner, except that extra provision for heavy pounding is made in the use of Grover spring washers at the fish plates. The ends of the rails are everywhere fang-bolted to the sleepers; and the rails themselves are electrically bonded with copper strip, copper riveted. The gauge adopted is 3ft. 6in., this being 6in. wider than the standard gauge in the island, and equally wider than the gauge on the Douglas-Laxey electric line. This departure from standard practice was adopted in order to ensure greater steadiness and safety on the steep gradients and sharp curves. The accompanying diagram of gradients (Fig. 2) will enable the reader to form an idea of the almost persistent steepness of this line from start to finish.

The middle rail is constructed on the "Fell" system. Its purpose, in the Snaefell line, is to serve as a guide, to prevent the cars from leaving the track, and to provide a surface for the grip of the powerful emergency brakes, with which every car is fitted in duplicate. In other places where the "Fell" middle-rail system has been introduced—notably, in the temporary light railway up Mont Cenis, before the completion of the tunnel—the centre rail has also been used to provide extra adhesion for the driving wheels. But, at present, on the Snaefell tramway, all the adhesion necessary is obtained with the four pairs of bogey wheels on which the cars are mounted. The middle rail is of rolled steel, double-headed, weighing 65lb. per yard. It is supported in the centre of each track, upon light wrought-steel ⎍ shaped chairs, spike-bolted to the cross sleepers, there being one of these chairs at every sleeper on each of the tracks. The security of the track as will further be seen by a glance at the accompanying views, is therefore fully assured.

To understand the more completely in what way this middle rail serves its double duty of guiding and braking, we will now turn to consider the cars and their equipment. At present there is a rolling stock of six motor cars, together with one or two trailer freight trucks for occasional use. Unlike the Douglas-Laxey line, there is in this tramway no passenger trailer behind the cars, but we understand that it is intended further to equip the line with a number of freight motor trucks. Each car is 35ft. long, and will seat 48 passengers. The cars are substantially built of timber, and are roofed over; but at present they are open, though it is intended to fit them with sliding windows. They are entered at the rear and front ends through the motorman's cabin, which is separated from the main part of of the car by a sliding door. Each car is mounted upon two four-wheel bogey trucks, each of which has a wheel base of 7ft., the diameter of the wheels being 24in. To each of the four truck axles a 25 H.P. Mather and Platt series-wound motor is geared. Thus every wheel of the car is a driving wheel, and the entire load is utilised for adhesion. There is, underneath each end of the car, a sand-box, provided with a system of distributing pipes for increasing the grip of the wheels on occasion. Every wheel is provided with a steel-shoe hand brake, controlled from both ends of the car; and during the descending journey the brake-handle demands constant watchfulness and plenty of muscle from the brakesman, both driver and conductor engaging themselves in this work. By the side of the ordinary brake-handle there is a similar arrangement for controlling the emergency brakes, one of which is fitted at each end of the car. These emergency brakes are kept slightly in action throughout the descending journey, but when fully in action they will quickly destroy the highest speed which the car might attain on the track. These brakes consist of two steel blocks or jaws, which grip the middle rail on either side, and which are actuated by a stout toggle connected to the brake screw.

Digitized by Google

Nearer the centre of the car, and on the same level as the emergency brake blocks, there are two pairs of horizontal flanged idle wheels, mounted on stout spindles so as to hang downwards from the frame of the truck. The wheels of each pair of these guide wheels roll on either side of the double-headed guide rail; and their flanges pass underneath this rail. In this way the truck is prevented from mounting, being held down by the stout flanges of the guide wheels.

An effective tractive effort of 2,840lb. is required to run a fully-loaded car up the track at the usual speed of nine miles per hour; and a proportionately greater tractive force would be required on starting, were it not that the line is constructed so that all the normal starts will be made on the level. In the event of the cars requiring to be started up the stiffest gradient —about 1 in 12—a much larger effort would be necessary. It will be seen, then, that a considerable margin of power must be provided in the motors, to meet these conditions. The motors are geared to the car axles by single-reduction 4 to 1 spur gear. The wheel and pinion are of hard cast steel, with the teeth carefully machine cut, to give smooth and silent running and a minimum wear. Normally the four motors will together develop a torque equivalent to a tractive force of 3,500lb. The motor armatures are surface-wound Gramme rings, with copper strip winding of ample section to stand heavy starting currents. The system is worked at 500 volts, and the four motors are connected together two-in-series and two-in-parallel. A normal current of from 120 to 160 amperes will pass through the car, thus, from 60 to 80 amperes through each motor.

Fig. 3 gives a view of the Laxey terminus, and shows the system of overhead conductors, and the type of motor car in use.

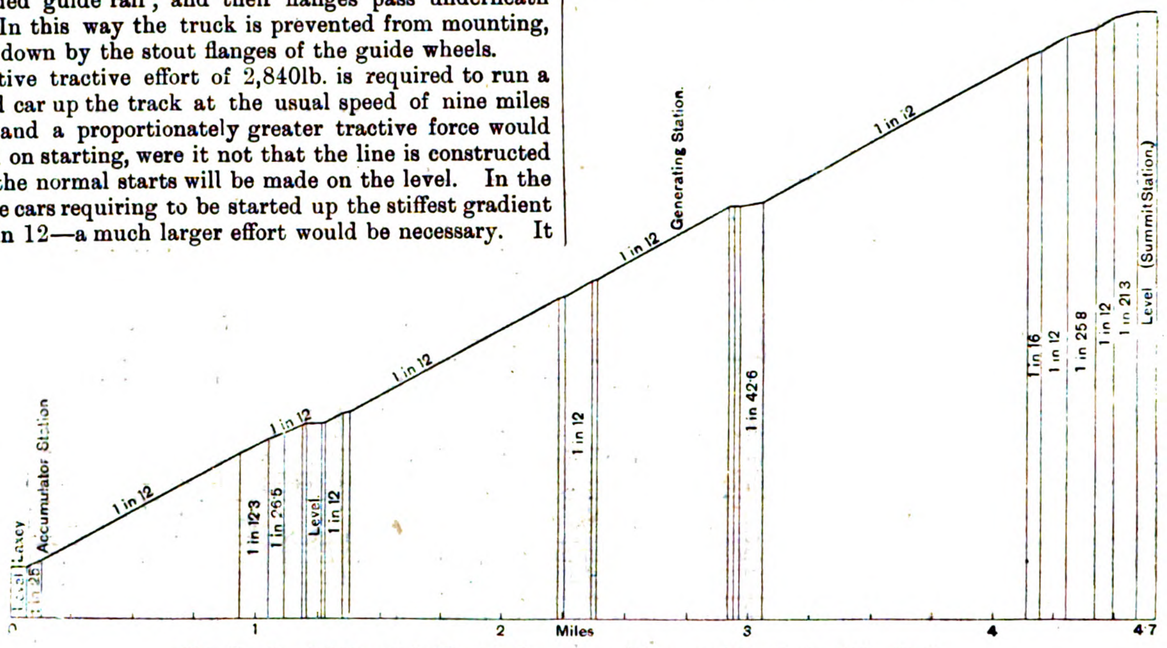

Fig. 2.—Snaefell Mountain Electric Tramway. Diagram of Gradients of the Route

Fig. 3.—Snaefell Mountain Electric Tramway. View of Cars, &c., at the Laxey terminus.

Power is supplied to the cars on an overhead system introduced by Messrs. Mather and Platt, and identical with that used by them on the Douglas-Laxey line. The general features of this system will be apparent from the accompanying illustrations. It differs essentially from the trolley system in the absence of the trolley. Between the two tracks, at distances of about 150ft. apart, light steel poles are grounded. Each pole carries a double bracket, or cross-tree, of steel, extending horizontally across both tracks. From each bracket on either side the conductor is suspended, by means of a riveted clip suspended from a bell insulator. The position on the bracket, of this suspension, depends on the curve of the line at each place; but there is nowhere that need for exact adjustment of the position of the overhead wire that is necessary with the trolley system. The conductor is of No. 0 hard-drawn copper wire, and at its lowest part it is a clear 16ft. 4in. above the track. Both up and down tracks are fitted with an overhead conductor, although, as a matter of fact, the down journey is performed entirely under gravity.

Upon each car there are fitted two sliding collectors, one at each end, which consist of flat steel bars extending transversely across the entire width of the car. These are mounted on the car roof, and are pressed against the overhead conductor by an arrangement of steel spiral springs. The two collectors are cross connected inside the car. By this system of collection the current is taken from the overhead conductor with an insignificant amount of sparking, a reasonably small wear of the conductor, and very little noise. Indeed, the sparking is only visible at night; the wear has been found on the Douglas-Laxey line to be remarkably small, a "flat" of only $\frac{1}{500}$th inch having been worn during the two years of running; while, as to noise, there is nothing of which the running of these cars reminds us more than a steam locomotive with steam slightly escaping from the safety valve.

The cars are started without altering the relative connections of the motors; or, in other words, the series-parallel system is not in use. Beneath the car bodies, well exposed to the air, are a couple of slate-framed sets of iron-wire resistances; and a start is made in a very simple manner, by throwing these into circuit, and gradually cutting out resistance as the speed rises. On the Snaefell line, the cutting out of resistance is left to the discretion of the motorman; and the only piece of interlocking is that which prevents the motorman from reversing his motors without previously switching them out of circuit.

There is but one actual feeding point in the entire length of the line, if we except the storage batteries which are connected to the lower extremity. This feeding point is at the point in the line contiguous to the generating station, at a distance of

Digitized by Google

2¾ miles from the Laxey end, and some two miles from the terminus at the summit. At this almost mid-point the overhead system is divided into two parts, an upper and a lower, each of which is separately controlled and fed from the main switchboard. The line may, however, be subdivided into smaller sections by means of switches in the lightning-arrester boxes along the route, and this will be done when it may be necessary to repair any section.

The generating station is a substantial stone structure, situated about 50ft. from the line on the under side of the mountain. Its chimney, of wrought iron, is on the upper side of the mountain; the furnace gases being carried beneath the tramway through a horizontal flue.

The building is divided into two parts, on slightly different levels. The higher and more spacious of these is the machinery room; the other is used as a boiler house. Within the

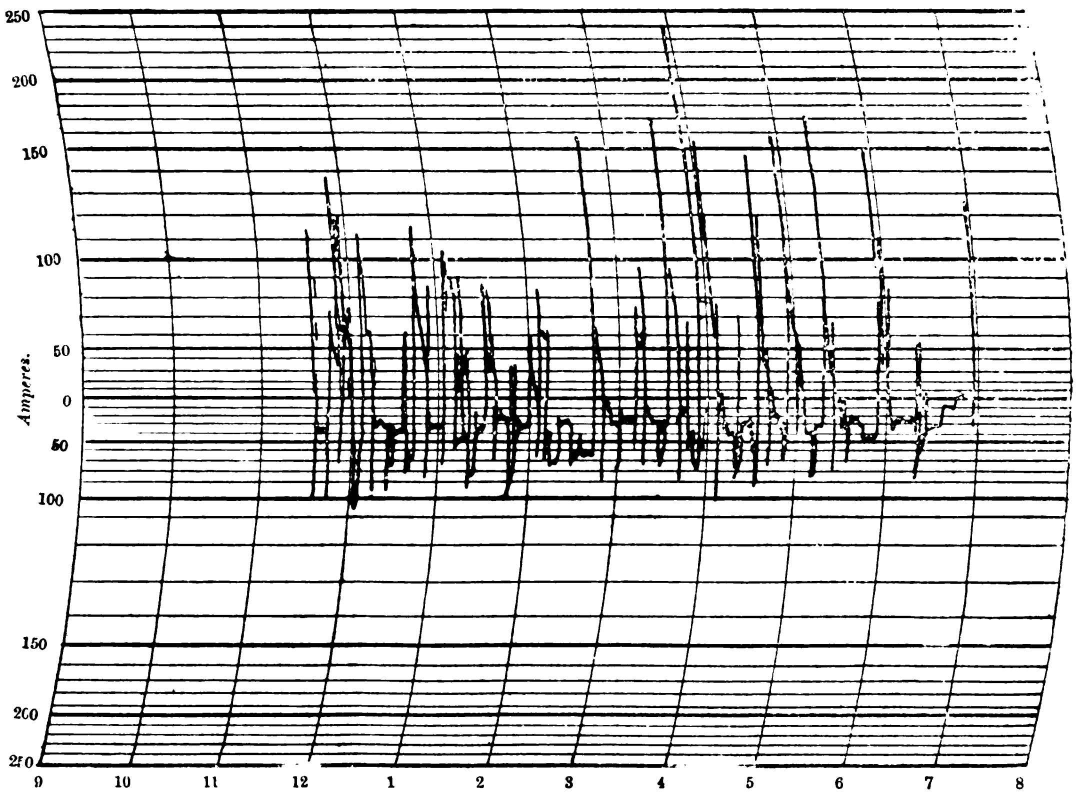

Fig. 4.

The choice of the site for the generating station involved many considerations. The centre of the route evidently was advantageous from the distribution point of view, but the fact of its being at an altitude of nearly 1,400ft. above the sea, and on the steep face of a mountain, was certain to increase the cost of running a steam station there, by augmenting the cost of carriage of coal. However, to locate the station anywhere

machinery room are five generating sets, each comprising a Mather and Platt 120 H.P. horizontal compound steam engine, belt coupled to a two-pole shunt dynamo by the same firm. The dynamo field-magnets are of the Hopkinson type, and the armature is Gramme wound with copper strip. Each machine, running at a normal speed of 900 revolutions, will develop a normal output of 120 amperes at 550 volts. The machines

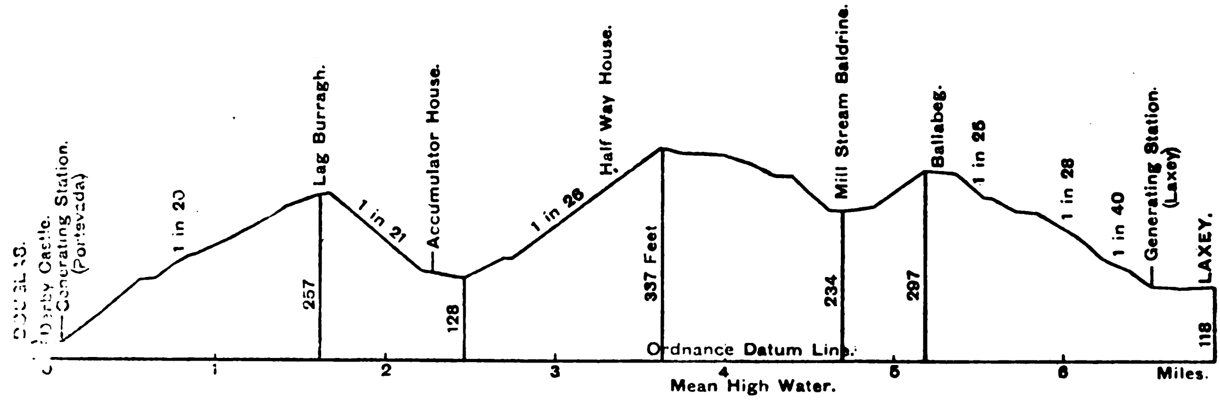

Fig. 5.—Douglas-Laxey Electric Tramway. Diagram of Gradients of the Route.

near Laxey town was rendered impracticable, owing to the impossibility of securing water rights. Accordingly, the site was fixed at the place already named, in order that water might be obtained for the boilers. Even here, however, water is not directly to hand; and some 800 yards away, beside a mountain brook, a small pumping station has been erected to raise water to a capacious tank just outside the generating station. This tank is capable of holding three days' supply of boiler feed.

are coupled to the engines by means of link leather belting running under adjustable jockey pulleys.

The steam engines are built on the horizontal, compound side-by-side plan, with outside flywheels. The cylinders are 20in. and 12in. in diameter; the stroke is 16in.; and the speed varies from 160 revolutions at full load, to 164 revolutions at light load. Each engine is provided with a Pickering throttle governor and a hand cut-off regulator. We noticed that the

Digitized by Google

Pickering governors were not belt-driven in the usual manner, but were driven by bevel gear from a light governor shaft, which was itself bevel-geared to the crank shaft. This modification happily obviates any calamity on the line, due to the governor suddenly ceasing to do its duty. The hand cut-off regulator is a modification of the Meyer slides. Instead of the usual hand wheel at the rear of the steam chest, there is a pawl and ratchet motion attached to the valve rod just outside the steam chest on the eccentric side. This obviates the extra gland on the further side of the chest, there being no valve tail-rod. The engines are of the "receiver" type, with cranks at 90deg., and the receiver, which consists of a cylindrical vessel placed behind the engines a little above the floor level, is provided with a re-heater in the form of a live steam coil passing through it. The flywheels are each 8ft. 6in. in diameter. Each engine is provided with a system of lubricators connected to one central oil tank.

Steam is generated in four Lancashire boilers, each 26ft. in length and 6ft. 6in. in diameter. The internal flues are fitted with Galloway cross tubes. This battery of boilers will generate steam, at 120lb. pressure, for about 700 H.P. The boilers can be fed either by means of a steam pump or by live steam injectors.

At one end of the machinery room is the switchboard, which, while simple and unpretentious in appearance, is well adapted to its duties. The board is built, in the usual manner, some little distance from the wall, with a passage-way behind it to enable the connections to be reached. The face of the board is fitted with two Kelvin multicellular voltmeters, one for each section of the line, *i.e.*, the portion above and the portion below the feeding points; it also is provided with an ammeter for each machine, a magnetic blow-out lightning arrester, and an automatic cut-out apparatus which will come into action in the event of a "dead-short" occurring anywhere on the system. By the side of the switchboard is the telephone box, which is in communication with both ends of the line and with the battery house at Laxey. The telephone wires are at present, by-the-bye, carried on the tops of the conductor poles; but we understand it is intended shortly to place them on separate poles.

Situated near to the lower extremity of the line, and electrically connected to the very extremity, is the storage battery. This comprises 246 of the "S.P." type of chloride storage cells; the "S.P." signifying that these are specially protected by means of asbestos cloth packing and by special arrangement of the grid, to withstand a very high rate of discharge, such as is inevitable in traction work; or even, for a short period, a complete short-circuit. The rated capacity of these cells is:—

176 amperes for 3 hours.	84 amperes for 9 hours.
112 „ „ 6 hours.	72 „ „ 12 hours.

The cells are contained in strong clear glass vessels, mounted in sawdust trays upon glass insulators, the whole of the battery being supported on a stout timber staging—on one level—set upon an asphalte floor. They are contained within the greater part of a neat wooden building, the lesser portion of which serves the purpose of a switch room, and is separated from the battery room by a wooden partition. We were particularly struck with the absence of acid fume and unpleasant gas from both these rooms, which are well ventilated and lit by means of two skylights running along the length of the roof.

The purpose of the cells is simply to serve as an electrical regulator of the pressure on the line, by which means the variations of supply to the cars might be made without undue fall of pressure and without imposing a sudden great increase of load on the generators. In regard to the steadiness of the pressure, the scarcely perceptible change in the brilliance of the car lights—which are run off the overhead system—when a car is started, shows what success has been attained. And, as to the sudden load on the engines, the gradual creeping-up of the dynamo ammeter readings, and the absence of serious drop in engine speed, show how useful are the cells in this respect.

The flux of energy into and out of this storage battery regulator is well illustrated by the sample of the battery ammeter records which is shown in Fig. 4. The parts of the record above the zero line represent current going out from the battery to the cars; the parts below zero represent charging current. It is a fact worth mentioning that hitherto the amount of charging from the line has practically balanced the discharge, so that the initial charge has been kept up. However, the switching arrangements at the battery house allow of the entire battery receiving a replenishing charge when necessary, and to effect this the entire battery of 246 cells is divided

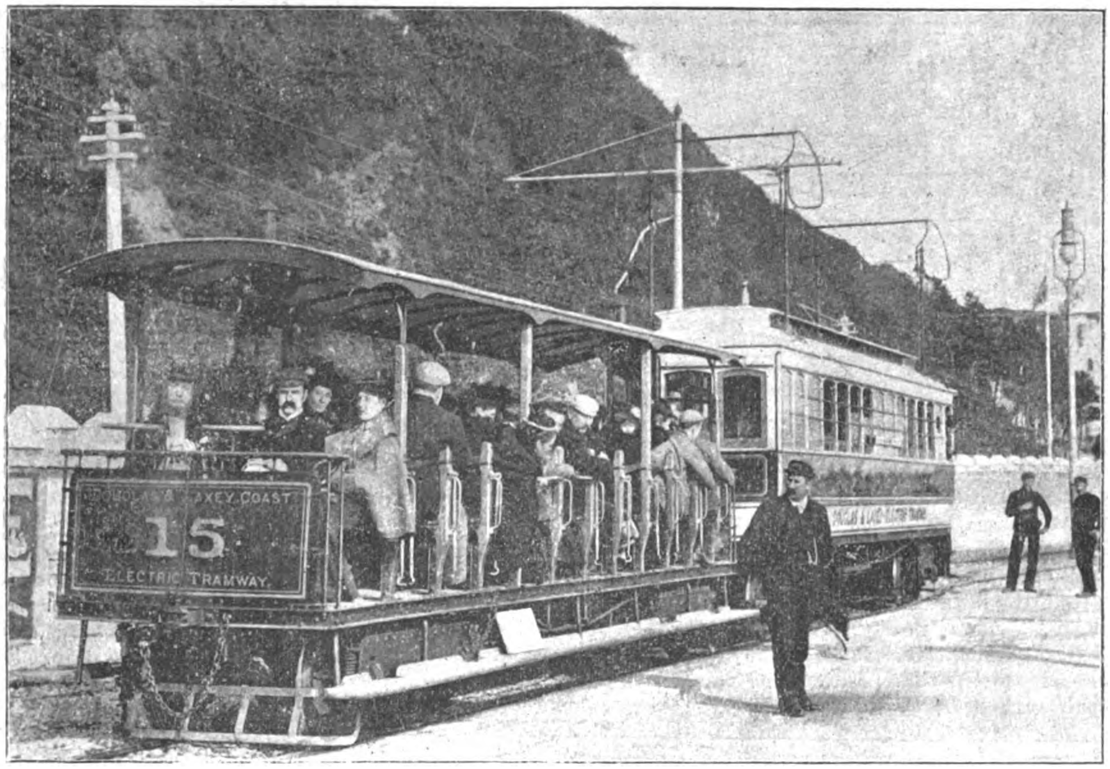

FIG. 6.—Douglas-Laxey Electric Tramway. View of Douglas Terminus, showing Overhead System. Motor Car, Passenger Trailer, and Arrangement of the Arc Lamps. N.B.—The *wooden* poles and wires strung to them are not connected with the tramway system.

into two equal portions, which are temporarily coupled in parallel across the system, these half batteries being charged at the requisite charging pressure by reducing, for the time being, the generating pressure. It may be mentioned, also, that it is not intended to run cars solely by means of the cells, as is done on the neighbouring line.

The contractors for the whole of the generating, storage and other electrical equipment have been Messrs. Mather and Platt, of Salford, who have departed from the lines of their former contract—the Douglas-Laxey tramway—only where experience has dictated or modified conditions have demanded. It is to their great credit that success has crowned their recommendation of the overhead system, and the adoption of the middle rail, in place of rack gear, on the steep gradients of this mountain line. We have mentioned that the civil engineers of this tramway have been Messrs. McKerrow and Fell, of London, by whom operations were commenced last January. The engineering operations throughout have been carried forward in the face of great difficulties; first, in the earlier stages, on account of the appalling winter; and later, owing to the earlier delays having made it necessary to work against time, so as to have the line ready for the tourist season. Some idea of these difficulties may be gathered from the facts that the whole of the generating and electrical equipment has been erected within seven weeks, and the entire overhead system of poles and conductors occupied no longer than eight working days for its erection. The credit for this enterprising piece of prompt working is to be given to Mr. R. H. Willis, the resident engineer appointed by the contractors; and its value is enhanced by the fact that the system started work in perfect order and without a hitch.

Our thanks are given to Messrs. Mather and Platt for permission to publish the illustrations and other particulars of the Snaefell mountain tramway; and they are extended to Mr. R. H. Willis and Mr. Cartner, in whom the charge of the generating station has been placed, for the kind courtesy with which they assisted us to survey the system while in operation.

While spending a few days in the Isle of Man, for the purpose of visiting the Snaefell line, we devoted some time to a further examination of the Douglas-Laxey line. As this last-named tramway is constructed upon a similar system to that at Snaefell, we have appended a few illustrations of it, and will conclude our account of the Isle of Man electric tramways with a few remarks upon it.

The Douglas-Laxey electric tramway was opened to the public on July 28, 1894, and some account of the system, as it then existed, will be found in *The Electrician*, Vol. XXXIII., p. 449. The particulars of the route are contained in the accompanying diagram of gradient (Fig. 5), an interesting comparison between which and Fig. 2, the section of the Snaefell line, may be made. The Douglas-Laxey system has two-fifths of its generating plant at the Laxey end and three-fifths at the Douglas end, and it is provided with a battery station at about one-third of the distance from Douglas, and a feeding point—connected by buried Callender cable to each generating station—at the middle of its length. The rolling stock consists of 13 motor cars, each equipped with two 30 H.P. motors and 12 passenger trailers, in addition to which a number of goods trailers are occasionally called into requisition. A view of one of the motor cars, coupled to a passenger trailer, is shown in Fig. 6, in which also the overhead system and the arrangement of the collector bars will be seen. It will be noticed, too, that upon some of the conductor poles arc lamps have been suspended. These are in use only at the Douglas end of the line, the lighting at the other end, as well as in the cars, being by means of incandescent lamps connected in series to the overhead conductor.

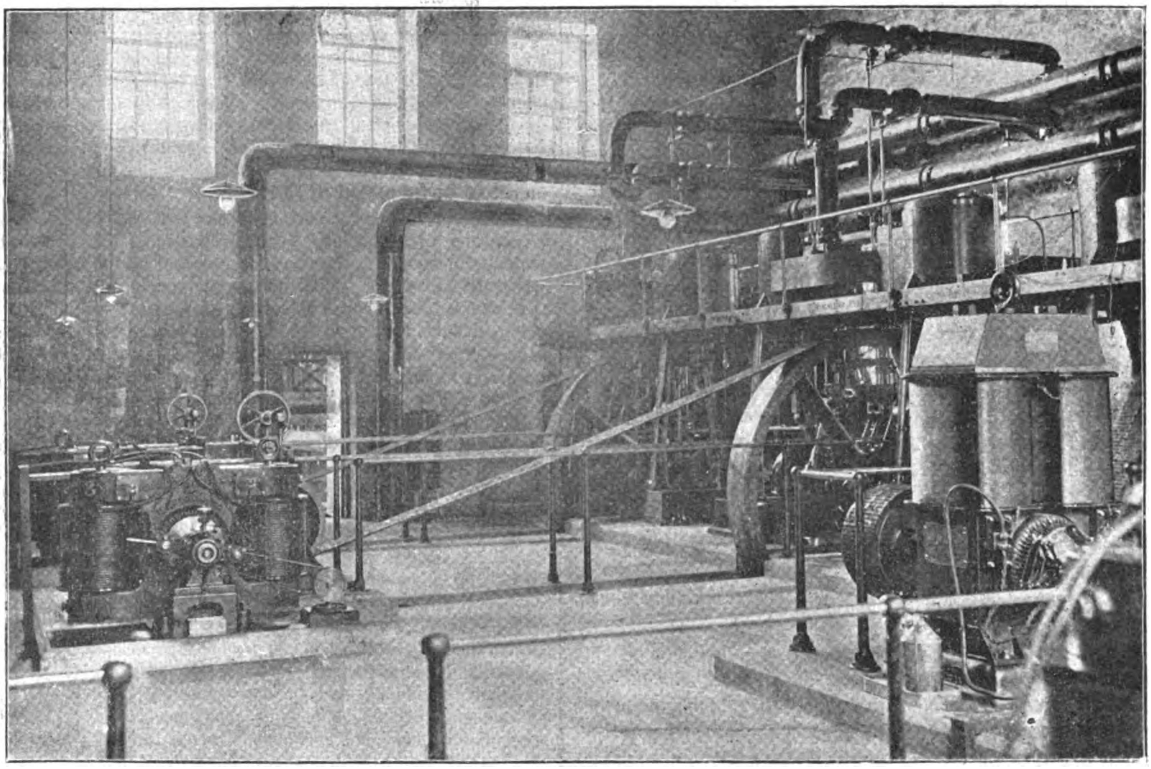

Fig. 7.—Douglas-Laxey Electric Tramway. View showing a portion of the Generating Plant at the Douglas Generating Station.

The rails are bonded with riveted copper strip, and but one per cent. of the total current normally returns to the stations through the earth itself. We noticed at the Douglas station an ammeter on which the actual earth-return current was being indicated.

There are five generating sets, each comprising a 100 H.P. Galloway vertical compound engine, coupled by means of a link leather belt drive to a Mather and Platt 500-volt dynamo. Three of these sets are situated at the Douglas station, a view of the machinery room in which is shown in Fig. 7. The remaining sets differ from these only in being placed on a shorter drive, and in being non-condensing, while the Douglas sets are condensing; and they are situated at the bottom of Laxey Glen, somewhat near the terminus at that place.

The battery station at Groudle Glen consists of a neat wooden structure, in one portion of which is a battery of 240 chloride storage cells, and in a separate room a continuous-current motor-generator for supplying the hotel, &c., with light. The cells have a capacity of 140 amperes for 3 hours, or 70 amperes for 9 hours. During winter occasional cars are

Digitized by Google

run on the batteries alone, these cars being rendered necessary partly because the line carries all the mails. There are no special mail cars, however.

Our thanks are due to Mr. J. Shaw, the resident engineer at Douglas, and to Mr. Aldworth, the general manager, for the courteous and genial kindness with which they showed to us their generating stations and line, as well as for permission to publish the illustrations of their tramway system which accompany this article.

It will be of interest to state that the principle and details of the electrical equipment of these two electric tramways in the Isle of Man were adopted and designed by Dr. Edward Hopkinson.

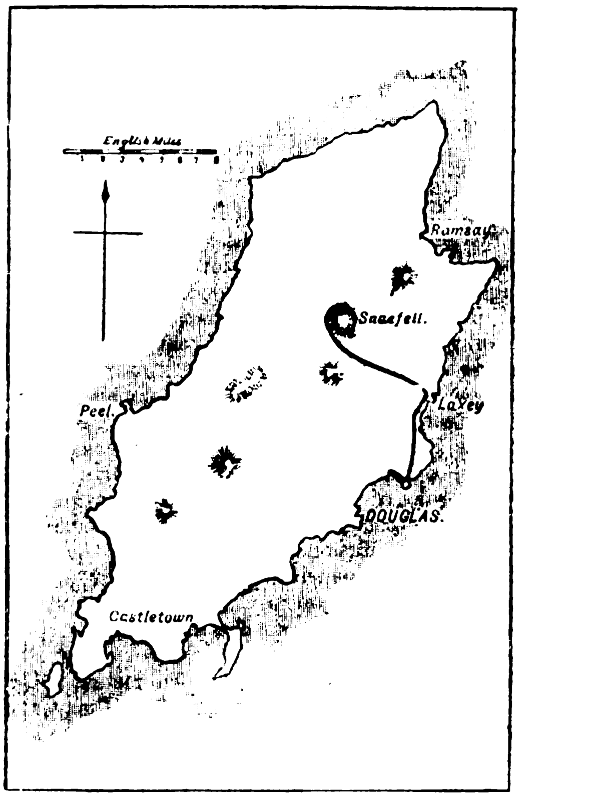

FIG. 8.—Isle of Man Electric Tramways. Routes of the two lines, shown thus ————

The accompanying map of the Isle of Man (Fig. 8) shows the routes of the two electric tramways. It will be observed that the one from Douglas does not join that from Snaefell at Laxey, there being a distance of some 200 yards or more between their respective termini.

We hope soon to see other parts of this interesting little island connected together by electric tramways; and judging by the enterprise of the Manxman in the past, we scarcely think we shall be disappointed.

THE INVENTION OF THE ELECTROMAGNET.*

BY E. BOISTEL.

In a recent article† with the above title my good friend M. G. Pellissier thought it his duty to call attention to a mistake made by Prof. S. P. Thompson in his well-known work "The Electromagnet and Electromagnetic Mechanism," and even to accuse him somewhat sharply of distorting the truth. As mere translator of of the book in question, I am personally in no way concerned in this controversy. I do not wish, however, to be considered as having accepted without inquiry or comment a statement that, according to M. Pellissier, disagrees so entirely with the irrefutable documents which may be found inscribed on the pages of history. I shall go somewhat deeply into the matter, although keeping myself within the limits of the article by M. Pellissier. Far from blaming his chauvinism, in which there is nothing unbecoming, I only ask M. Pellissier to allow that I am myself as careful as he of the glory of our great men and equally desirous to give to each his due; but I entreat M. Pellissier to moderate his youthful ardour. He who proves too much, proves nothing.

That being settled; to the question at issue. M. Pellissier, to make good the belief in which he, in common with so many others, has been brought up, appeals to the testimony of all writers who have written on this branch of electric science. Now, without stopping to search right through these works, I will admit that the discovery of the electro-magnet was formerly, at any rate, attributed to Arago (one only lends to the rich). But I have also discovered, much to my astonishment, that the best recent works, in which I hoped this point would be in some degree cleared up, are absolutely silent about the matter. Is this to be regarded as the consecration of a widespread belief, or is it an act of prudence, the motive for which is the often exceeding difficulty of settling these questions of priority and the well-grounded fear lest an idle dispute without profit to science or to practice should be started? I cannot tell, and merely content myself with recording the fact. As to what may have been stated in early writings, it is enough to call Montesquieu's saying to mind :—"There are things which all the world says, because they have been said before."

I will confine my references solely to the documents quoted by my friendly opponent, which are, as a matter of fact, the most authentic. These are the reports of the Bureau des Longitudes (1820); the communications made to the Académie des Sciences, taken from the *Moniteur* of that year, the *Annales de Chimie et de Physique*, also of 1820, all collected in the complete works of François Arago, published in 1854, and in Vol. IV. of which I find, in Scientific Notices II., under the heading "Electro-Magnetism" (posthumous work), p. 405, *et seq.*, the complete history of the question, and the general principle enunciated on p. 429 by Arago himself: "I maintain as a general proposition that publication, be the mode of it what it may, is the only evidence which ought to be admitted in the history of science."

Here we certainly read that the voltaic battery *magnetises soft iron;* but we must further inquire iron of what shape and under what conditions. The first communication to the Académie des Sciences tells us: "The junction (straight) *wire* which establishes communication between the two poles of the Volta pile becomes covered with *iron filings* like a magnet. The wire does not, therefore, merely act on already magnetised needles, but it also develops magnetism in iron which has not previously been subjected to magnetisation. Further, *non-magnetised compass needles* are deflected under the influence of the junction wire." I have carried the quotation further than M. Pellissier. The detailed account of the discovery, in which the question is always of *iron filings*, follows, until we come to a junction wire of the size of an ordinary pen tube. Arago certainly says: "Oersted only discovered the influence exerted by the voltaic current on a previously magnetised needle. Repeating the 1819 experiments of the Danish physicist, I observed that the same current develops magnetic virtue in *strips of iron and steel* which to start with were entirely without it." The matter in hand here, however, is only a repetition of Oersted's experiment applied to iron, and although the phrase "strips of iron" is used, no mention is made of them in the experiments, and non-magnetised compass needles must necessarily have been of steel. Arago observed, moreover, in this first experiment that the junction *wire* only communicates a *momentary* magnetisation, ceasing with the current, to the soft iron. But it is solely *the wire* and the *straight* wire with which he is occupied. He tries or proposes to try metallic *wires* of different mass, shape, and diameter. "The junction *wire* of copper," he says in conclusion, "is endowed, as we see, with a very powerful magnetic virtue, so long as it is in communication with the two poles of the battery. I have even succeeded more than once in finding traces of this property in *it* some moments after complete interruption of communication between the two poles; but this phenomenon is very transient. . ." In this memorable experiment the illustrious academician therefore only investigated and observed a single fact; the property possessed by a *straight* metallic *wire*, traversed by a current, of magnetising steel and momentarily magnetising and attracting particles or fragments of iron, a property belonging to the wire and not at all to the iron. But let us go on, book in hand.

In the following chapter—The Magnetisation of a Needle by means of the passage of the Electric Current through a Helix—it is no longer in any way a question of soft iron but only of *steel* needles in which, as Arago himself states, he had not succeeded in attaining constancy of the polar points, and which he had only succeeded with some difficulty in magnetising at all. Ampère had as yet only made his important discovery of the mutual and reciprocal action of two rectilinear wires traversed by currents, from which he had deduced by analogy his theory of the elementary constitution of magnets. It was at the very moment when he was carrying out the experiments which Arago had just shown him that his genius suddenly inspired him with the idea of winding the wire in a helix and placing the *steel* needle inside. "He hoped in this way to attain a more powerful magnetisation and a constancy

* From *L'Éclairage Électrique*, July 20th.

† *L'Eclairage Electrique*, June 8th, p. 472.

Digitized by Google

of the polar position, which was not obtained by Arago's method." The experiment was straightway carried out in the presence of the two *savants*; it is classical. Arago states that "after a sojourn of a few minutes within the helix the *steel* needle received a tolerably strong dose of magnetism, the positions of the north and south poles being, moreover, in exact accordance with Ampère's forecast, based on the direction of the elements of the helix and on the hypothesis that the electric current traverses the junction wire by going from the zinc end of the battery to the copper end."

The *solenoid* was from that moment created by the genius of Ampère, to whom Arago did ample justice by giving him all the credit of the experiment and trying to explain the relative failure of his own first attempts.

From this the two physicists passed on to the investigation of the action of two consecutive helices, coiled in opposite ways, and to the formation of consequent poles in *steel* needles. The magnetic action of the solenoid was so well understood that Arago recognised that in his first experiments he had only polarised his knitting needle with the rectilinear wire, owing to his having rolled the wire round its ends in order to support it the more easily.

Apart from this last, thrown out by the way, I do not think one could find in the above quotations, which are a faithful summary, anything of a nature to make good for Arago the discovery or the claim to the discovery of the electromagnet. He only had in view the magnetic properties acquired by a metallic *wire* traversed by a current and showing itself by *the momentary attraction of iron filings*, and the constant polarity given to *steel* needles subjected to the influence of *a helical current due to Ampère*, and nothing, it seems to me, justifies the following assertion of M. Pellissier: "The electro-magnet was by these researches created in its fundamental essentials—namely, the temporary magnetisation of *soft iron* by a conducting wire wound in a helix several times *round the iron, in order to increase the intensity of the magnetisation.*" Nor the following either: "The experiments of Sturgeon only differ from those of Arago in that he employed *a larger core.*"

Neither in Ampère's nor in Arago's experiments is there any question of *core*, and everything depends on that. They discovered and clearly defined the magnetic properties of the *solenoid*, which are also to be found in the electro-magnet, but they had no idea of *reinforcing* its external magnetising influence *by the insertion of an iron core*, an essential feature of the electro-magnet. That they did much to open up the path no one denies, but they did not invent the electro-magnet. As far as they were concerned, the iron was *passive*, at the most it was the armature of Ampère's solenoidal magnet, since *steel alone was subjected to the current in the helix.* These two great *savants* invented, if one likes to say so, the *air-core* electro-magnet, but not the iron-core one we know to-day. This great advance would suffice to ensure their renown had they made no other discovery. The renown of Archimedes, Lavoisier, and Faraday is not affected by the numerous applications of the lever which have been made since the days of antiquity, or by smokeless powder, or by Pixii, Pacinotti or Gramme machines; but it would never do to attribute the latest inventions to the earliest men. The successive labours of the *savants* of the entire world lead us day by day towards new discoveries, but, whatever M. Pellissier may say, to my mind the *invention* belongs to him who, possessing possibly much less genius, and profiting by the progressive investigations of his predecessors, puts the thing into a shape which makes it immediately utilisable, and points out its true value.

Finally there is an argument (not *ad hominem* but *ex homine*) which we will only introduce at this stage, and which has its worth. It is drawn from the character of the man. If Ampère was modest, Arago did not willingly allow people, and quite rightly so, to tread on his heels. He objected very vigorously to any encroachment on his domain, witness his famous controversy about the Barlow wheel a few years later. He was aware that: "Those who observe a fresh scientific fact must expect to have it denied at first, then later on to have its importance and utility disputed. Next comes the chapter of priority, when obscure and insignificant passages, unnoticed until then, crop up in crowds as manifest proofs of the antiquity of the discovery" (Arago *loc. cit.*), and whether provoked or not, he would not have failed to have had justice done to himself before his death could he have claimed on any grounds whatsoever priority in the invention of the electromagnet, which had by then become widely used.

After referring to Arago's and Ampere's experiments de la Rive moreover remarks: "*Later on* people tried to wind *a bar of soft iron* bent into the shape of a horse-shoe with a silk-covered copper wire helix. . . ." As to Arago's note on "The Principle of Electric Telegraphs," it must not be forgotten that it is posthumous, that it does not refer to experiments of certain date, and that by reason of the very subject it must have been written at a very advanced age when the electromagnet had come into practical use.

M. Pellissier is perfectly right as to the little noise made by Sturgeon's experiments; even Faraday, in his "Experimental Researches" (1831), attributes the electromagnet to Prof. Moll, of Utrecht, who had simply bought one of Sturgeon through the London instrument maker Watkins. But the same may be said with regard to the supposed invention by Arago, to whom Faraday might, with equal reason, have attributed it, and who, we may feel sure from his nature, would not have failed to have made good his claim of priority.

Let us, my dear M. Pellissier, console ourselves for the loss of our illusions by the hope that we have jointly assisted in the elucidation of an interesting point of scientific history. Arago, or rather Ampère, may be the grandsire of the electromagnet, but he certainly is not the sire, *since he seems never to have introduced iron into a magnetising helix*, and we may yield to Prof. S. P. Thompson, the promoter of this courteous polemic, the same confidence that you rightly give to his usually very well-founded science. The labours of our two great *savants* will suffice to render their genius immortal. Let us shake hands and admire them.

CORRESPONDENCE.

MAGNETIC UNITS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Before the Ipswich discussion—if there is to be a discussion—a few additional lines (not megalines) may be useful in calling attention to a few aspects of the matter which might possibly get overlooked, judging from your "Correspondence" columns of this week. It is easy to exaggerate the oddness of a new name so long as it is unfamiliar, and once upon a time I suppose *ohm* and *megohm* suffered under this disadvantage—in fact, I myself remember that time; but the term ohm now sounds homely enough, although it does not convey its meaning on its surface so clearly as the equivalent term *volt-per-ampere* may, for the sake of illustration, be supposed to do; and this fact, so far from being an objection, is a positive aid towards its free and easy diffusion among operatives and line-testers. Again, the term *volt-ampere* would do instead of *watt*, yet the latter term has come into use; and, similarly, the term joule is simple and handier, although less self-explanatory, than volt-sec-ampere.

If compound words, like ampere-turn instead of gauss and volt-line instead of weber, are enforced for very simple and fundamental quantities, it seems to me that the policy, though plausible for the moment, will be a short-sighted one; because it will then be difficult to proceed further with the formation of compounds, such as weber-per-gauss, which is a unit of permeance, and weber-gauss, which is a unit of energy (and may easily be made a joule). Again, the term *weber-turn* seems to me likely to become in the future nearly as useful as *ampere-turn* has proved itself to be, but it cannot be introduced unless a single name (no matter much what) is affixed to the C.G.S. unit of N or to some multiple of it.

But some of your correspondents appear to hold that no unit names at all are wanted; because if asked hastily for a boiler-pressure the reply "80" is amply expressive. Similarly it might be truly said that when asked in casual conversation for the length of a lease or the age of a man, the reply "99" is completely intelligible; but surely it would be inconvenient not to be able to add the term "years" whenever for precision or completeness it was desirable? And such a term, though meaningless in itself, may be legitimately employed without always having to think what a *year* precisely means; nor would the ordinary man feel grateful if told that he might employ the more expressive phrase *earth-orbital-period* instead. Surely those who doubt the usefulness of names for units (of course introduced in moderation, and after thorough consideration, by collective authority) can hardly remember the vague era before the terms *volt* and *ampere* existed, an era when no one had any instinctive "feel" of what current they were getting out of their Grove or Bunsen cells, which were then almost the only available large-scale source of electromotive force.

And one more point I must reiterate, though it is admittedly a matter on which a precisionist and a teacher must feel more strongly than practical men and engineers, the reason for adding "pounds per square inch" in a specification of pressure is in truth *not solely* because other countries use kilogrammes

Digitized by Google

per square centimetre; part of the reason is of a much more fundamental character, lying at the basis of the whole idea of absolute measure; nor would it be at all satisfactory silently to assume the C.G.S. system in every case and record only the numerical portion of quantities, although this may be often conveniently done in colloquial haste. Perhaps it has not been clearly noticed by everybody that the unit is just as important a portion of the specification of a concrete quantity as the numerical portion. The height of *anything whatever* is 360 if the appropriate unit be chosen; the figure applies equally well to the solar prominences, to a fly's proboscis, and to St. Paul's Cathedral, only the units are different.—Yours, &c.,

Sept. 6, 1895. OLIVER J. LODGE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Being so far from the centre of civilisation, I am afraid the remarks you have asked me to make on the subject of the correspondence on magnetic units in your columns will be late, and fall rather flat after the British Association Committee have had their say.

I never can understand the objection to having authorised names for any units at all. Nobody need use them unless they like. Even Mr. Ravenshaw in his own works may, for instance, use the unsystematic units he has accustomed himself to without doing anybody else any harm. As Mr. Esson very sensibly says, "By all means let the scientists invent names for units." The proposal that they be allowed to grow, which has been made by several sensible men, has not in the past led to satisfactory results. We have ounces and grammes and leagues and versts as the result, and, though we are an insular nation, it is to be hoped that the question at issue will be viewed from the international standpoint. Even in the one matter of magnetic force we have names galore growing up. "Lines" and "scots" and "gausses" and "thoms" and "hops" and "mags." There is evidently a preponderating preference for a monosyllable, and yet several consider that the names "magnetic line" and "ampere-turn" are short enough for convenience. There are, no doubt, objections to personal names, but as this has been a matter of international agreement, it will probably be best to abide by that decision, and continue the system. Questions of jealousy between nations as to the name to be chosen are so amusing it would be a pity to lose these disputes. On the other hand, it is a very good rule to avoid the names of living men, especially when they themselves object.

As regards this question of giving names to units, I think the consensus of opinion is that names should be given to them, and are as a matter of fact being invented by engineers for their own convenience, and so far the appeal for help in deciding this question has been helpfully responded to by engineers, and has led to a valuable contribution to the discussion.

In respect of the much more difficult questions as to the coefficient of induction and of magnetic permeability, hardly any help has been given by engineers, or indeed by any of the correspondents. Mr. Heaviside is in favour of $\mu = \frac{dB}{dH}$. Most of the correspondents, including Prof. Ewing, to whom Mr. Heaviside appealed, *assume* that no other definition than $\mu = \frac{B}{H}$ is possible. The matter is essential complicated. The phenomena themselves are very complicated, and there does not seem any prospect of making them simple. Personally, I am rather inclined to $\mu = \frac{dB}{dH}$, but we really want two different names for the two different quantities, and the only serious question is, to which shall the name "permeability" apply, and what name shall be given to its unit. From the almost universal agreement apparent from the answers it would seem that $\mu = \frac{B}{H}$ has been up to this always called the permeability, and if so some other name should be invented for $\frac{dB}{dH}$; for it is dreadfully confusing to have the same name for two different quantities, especially to students, whose claims in a matter of the kind are certainly deserving of consideration. Those who find it unnecessary to distinguish between $\frac{B}{H}$ and $\frac{dB}{dH}$ may stick to one or other of them, and it is pure dog-in-the-manger for them to object to another name for a quantity that they never use.

As regards the coefficient of self-induction, I think it would be a very great misfortune if the British Association were to set itself up in any degree in opposition to the Chicago International Congress. May be the "henry" is not the absolutely best unit, but a confusion of tongues, a new babel of names, would be far worse than any little inconvenience from using the "henry," and when once accredited representatives of a large number of civilised nations have settled upon a term it is most important that all civilised nations should submit to the result and substitute, in science and manufactures at all events, arbitration and agreement for war.

As regards the great 4π question, I entirely agree with Mr. Heaviside in thinking that it is a great misfortune that our units have been founded on the present definitions of a unit pole instead of upon the one he advocates, but I do not at all agree with him in thinking that a change is now possible. The existing inconvenience arising from 4π is not really very serious, and when one considers the enormous difficulty that exists in changing our really terribly inconvenient weights and measures, which costs our country so many years of the life of each child, and so many millions of money in keeping calculators at work who might be employed in something useful, I see no possible prospect of changing our present very seriously inconvenient system of electromagnetic units. There are so many other things better worth doing that I would be very sorry to see my scientific friends engaged in putting their shoulders to this wheel with that expenditure of time and energy that would be required to accomplish anything, especially when the prospect of accomplishing anything is so very minute.—Yours, &c.,

Fernbank, Howth, GEO. FRAS. FITZGERALD.
Co. Dublin, September 10, 1895.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: When anyone presumes to offer an opinion on such a subject as this, either he should be a well-known man whose views already have weight in the estimation of others, or he should present some credentials to show that although his qualifications may not be generally recognised, yet he has entered into the matter sufficiently and done enough work in the field to show that he ought to know what he is talking about.

Although I have written a good deal on electrical subjects, it has been almost entirely on what is called the practical side, and, therefore, when attempting to say anything publicly on a theoretical question, it is perhaps desirable to mention briefly the grounds on which my opinions are formed, and the nature of the practice which has led me on to form those opinions. This is my apology for entering rather more fully into personal matters than modesty would dictate under other circumstances. I also think that often general truths are better conveyed in a personal narrative, particularly when they are of a complicated and debatable nature.

Bell's discovery of the telephone was almost contemporaneous with my leaving school, and I immediately made a telephone and Hughes's microphone, and did a good deal of experimenting with them. Four years afterwards I was an engineer in the service of the United Telephone Company, and at once began to take great interest in the construction of telephonic apparatus and the propagation of telephonic currents. During 1885 and 1886 I had charge of their trunk line and testing department, a period during which the Brighton being the first long-distance line in England, was established, and which was a crucial period in the history of telephony in many ways. During these two years I was almost constantly at work experimenting on cables, the influence of capacity and self-induction, and also endeavoured to read all I could on the subject of alternating currents. Late in 1885 I brought out, with Mr. Ferranti, a closed circuit translator coil, which has since been employed

Digitized by Google

largely by the Telephone Company. In order to experiment on these coils I made a quadrant electrometer and other apparatus, and spent most of my spare time for nearly six months in working at the problem. Afterwards I joined Mr. Ferranti at the Grosvenor Gallery, and was there while his first high voltage machines were built. Since then I have been more or less intimately connected with alternating current work. The growing importance of this work during the last two years, coupled with an increasing feeling of the crude and unsatisfactory character of much of the alternating plant at present in use, has led me to pay much attention to the principles governing the design of such plant. During the last eighteen months I have gone through calculations of most forms of alternator in use, with a view to ascertaining their relative efficiencies, strong and weak points, and to ascertain how nearly calculations would bring one to the results of practice. I have also carefully studied the effect of capacity and induction in distributing systems with a view to make up my mind which was the best. Although, therefore, I may not occupy the recognised position as a designer of plant which everyone concedes to several of those who have written deprecatingly of Dr. Lodge's proposals, from what I have said above, it may at least be allowed that I have not been inattentive to the subject, and therefore, whatever my competence to express an opinion, which I do with much diffidence, at any rate my views have not been formed without careful consideration and without a pretty extensive and practical knowledge of the subject.

Now, as I do not pretend to be an original thinker, I have had to go for my knowledge to standard works, and of them I have found none which can bear comparison with Dr. Lodge's "Modern Views of Electricity" and Mr. Oliver Heaviside's "Electromagnetic Theory" for giving clear and comprehensive views on theory, and no work on the practical side to compare with Mr. Kapp's two volumes. The great value of other works, such as Dr. Fleming's, I also thoroughly recognise, but the above works I have gradually come to constitute my standards, as I have found them the most helpful in case of need and difficulty. In speaking thus I do not for a moment wish it to be understood that I understand everything Dr. Lodge, and especially Mr. Heaviside, say. I only wish to have it inferred that, so far as I have been able to understand them, I have found their views and explanations reliable and of the greatest value, and having fully ascertained this, I naturally am ready to accept their lead and guidance in further developments, which in some measure may be beyond my scope.

Now, in all my work in this field I have felt more and more the absolute necessity of a clearer understanding and definitions of electromagnetic quantities and actions. It is possible to wade through the design of an alternator by the use of various 10^8ths or 10^9ths, plus or minus as the case may be, and with the aid of that horrible mystifier the "coefficient of self-induction," which has played such a conspicuous part the last few years; but it is not the right way to go about it, and it is all the more roundabout and difficult when one tries to explain results to others. Things must have names if they are there, and the simpler ones the better, and the magnetic units have just as firm and as sound a basis as the physical ones.

Most alternating work is now designed in a rough manner, and without attention to the finer points, and this is why the efficiency of alternating plant is not as good as it should and might be. Again, to this confusion about electromagnetic quantities, and the basis on which they rest, is due the fact that people not clearly grasping them cannot measure them accurately, and do not feel proper confidence in the results even when they are properly measured.

To introduce certain units which define these quantities, and allow them to be explained clearly, is, therefore, not to add to complication, but to get rid of it, and besides that the everyday problems of electricity would be much better treated by the use of such units and the banishing of that miserable term "lines," and the inaccurate and misleading ampere-turn, into the background.

I must own that I found so many new terms very confusing when I commenced to read Mr. Heaviside's work, but then I put this down to my own ignorance, and not to want of lucidity on Mr. Heaviside's part, and in time I came to see that that was the correct view. Having found Dr. Lodge and Mr. Heaviside sure and reliable guides in this difficult but interesting and most important field; having found that they understood and could explain problems which I see will soon be of the greatest practical and commercial importance, and they having found certain names and units desirable in order to explain and deal with these problems, it, to me, savours rather of ignorance and insufficient acquaintance with the subject than of anything else to say that such terms are not needed, and that the old ones are good enough.

As to the precise values which are to be taken as units, I am perfectly content to leave this to those who have made theory a special study, particularly as I think it probable that in another ten or fifteen years it will be found advisable to make a fresh start with a complete new set of electric and magnetic units, arranged on such a basis as Mr. Heaviside has indicated. Consequently I am not prepared to split hairs over the question of dimension, but there is no reason why the quantities themselves should not be defined in some definite and understandable unit as soon as possible, so that they can be thought, talked and written about with facility.

I trust, therefore, Dr. Lodge will not be discouraged at the cold reception he has met so far. It appears to me that his work is not only a good one, but has been exceedingly well done, and although I do not quite agree with him, especially on the 4π question, on which I side entirely with Mr. Heaviside, particularly from an educational point of view, yet I consider such matters of secondary importance as compared with the necessity of quickly and intelligibly defining magnetic relations and quantities. Apologising for the length of this letter,—Yours, &c., G. L. ADDENBROOKE.

LEGAL INTELLIGENCE.

Pembroke Town Commissioners v. Dublin Southern District Tramways Company (Limited).

This adjourned application for an injunction to restrain the defendant Company from breaking up or excavating the roadway between the tram-rail and the footpath in the township of Pembroke came before Mr. Justice Murphy, at Dublin, on Tuesday last. Full particulars of this case were given in our last issue, and Mr. White, Q.C., who now appeared in support of the application, said the Tramway Act of 1893 gave no power or right to the defendants to place electric wires underground. The only power which the defendants had was that of putting down poles to carry the overhead wires. The defendants proposed to dig up the township roads and lay down wires and cables, although an undertaking had been given by them that only an overhead system would be adopted. An affidavit made by Mr. J. C. Robinson, the secretary and manager of the defendant Company, stated that the overhead wires were insufficient to carry a continuous current along the whole line, but this difficulty would be got over by underground feeders of much larger dimensions and less resistance. His Lordship here said that, though it was a serious matter to interfere with the rights of the Commissioners, it would be equally serious to interfere with and prohibit the execution of the Company's works. Messrs. Sullivan, Q.C., and O'Shaughnessy, Q.C., appeared for the defendants, and resisted the application, but stated that they were willing to enter into an undertaking to hold themselves responsible for any loss, damage or injury caused by the opening up of the streets or to take up the wires again if the Court so directed, and on these terms his Lordship refused the application.

Roumanian Petroleum.—According to the *Journal* of the Society of Chemical Industry the Austrian Vice-Consul at Plojest reports a decreased production of petroleum in Roumania last year. The best results are still obtained from shafts, bored wells being too narrow to permit the ready removal of sand, and being also liable to silt up. In Glodeni—Dambovitza district—over 900 tank-wagon loads of crude oil were obtained. The Campina wells yielded over 800 car-loads, and the production in Doftaneti and Bustenari was increased to some 700 to 800 car-loads by the sinking of new shafts to depths of 40 to 120 metres. About 200 loads in all were obtained from various scattered districts. The employment of residuum for heating purposes, as well as of refined oil and benzine for motors, is on the increase.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

SPECIAL NOTICE.—The 1895 (thirteenth) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is READY. In addition to the old well-known features of the book, which are brought up to date, a quantity of new and useful matter has been added, rendering the book more than ever indispensable to the Electrical, Engineering, and Allied Trades. Price, 7s. 6d., post free 8s. 3d., abroad 9s.

The Edition for 1896 is in active preparation, and orders for Advertisements and Subscriptions can now be sent in.

NEW BOOKS AND EDITIONS.

The following New Books and Editions of "THE ELECTRICIAN" SERIES *can be obtained of the Booksellers or direct from the Publishing Offices :—*

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett ; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming. M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

TENDERS INVITED.—The Urban Sanitary Authority of the Borough of Chepping Wycombe (Bucks), invite applications from public companies for working their Electric Lighting Order for a term of years. Tenders must be sent in by noon of October 14th to the office of the Town Clerk, High Wycombe, where a copy of the Order can be seen and all further particulars obtained.

——— The Electric Lighting Committee of the Harrogate Corporation require tenders for the supply and erection of the following plant :—(*a*) Lancashire boilers, economiser, feed pumps and accessories ; (*b*) steam alternators, condensers, fittings, &c., steam exhaust feed and sundry pipes, valves, &c. ; (*c*) switchboard and instruments ; (*f*) transformers and accessories ; (*g*) meters ; (*h*) overhead travelling crane. Specifications may be obtained from the Borough Surveyor, Harrogate, and tenders, addressed to the Town Clerk, Municipal Offices, Harrogate, must be delivered on or before the 30th inst.

——— The Building Committee of the Harrogate Corporation are prepared to receive tenders for wiring the new Montpellier Baths for the electric light. Specifications, &c., may be obtained from the architects (Messrs. Baggalay and Bristowe), 66, Victoria-street, London, S.W., and tenders, addressed to the Town Clerk, Municipal Offices, Harrogate, must be in by the 30th inst. Some particulars will be found in our advertisement columns.

——— The Huddersfield Industrial Society invite tenders for lighting by electricity their boot and shoe and confectionery departments, &c., in John-street and Albion-street. Tenders by the 16th instant to the Society, Buxton-road, Huddersfield.

——— The Board of Control, Dublin, require tenders for the supply and erection of two direct-coupled steam engines and dynamos, a battery of accumulators, main switchboard, &c., for the lighting of the Purdysburn Asylum, Belfast. Tenders to Secretary, Board of Control, Custom House, Dublin, by 10 a.m., 28th inst.

——— The Vestry of Shoreditch invite tenders for insulated electric mains, conduits, and drawing-in boxes, to be laid in the parish. Tenders by four o'clock on *Tuesday next.*

——— The Gravesend Town Council invite tenders for supplying and fixing a telephone and connections between the Sanatorium and the office of the sanitary inspector and the police station. Tenders by 20th inst.

——— The Gas Committee of the Manchester Corporation invite tenders for about 15 tons of copper strip. Tenders by the 20th inst.

——— The Dundalk Town Commissioners invite tenders for the erection and maintenance of the necessary plant for lighting the town by electricity from July 1, 1896. Tenders by October 7th.

——— The local authorities of Vilich, Obercassel, Oberdollendorf, Niederdollendorf and Königswinter have decided to construct an electric railway from Bonn to Königswinter or to Honnef. Plans and projects by 21st inst. to the Bürgermeister, Vilich, Germany.

TENDERS INVITED.—The Corporation of Eccles invite tenders for the supply and erection of Lancashire boilers, alternating-current dynamos and engines, cables, street boxes, &c , and transformers. Plans, specifications, &c., may be seen at the offices of the Town Clerk, or of the Consulting Engineer (Mr. S. V. Clirehugh), Temple Chambers, Brazennose-street, Manchester, on and after the 18th inst. Tenders must be sent in to Mr. Geo. Wm. Bailey, Town Hall, Eccles, by 12 o'clock noon on the 30th inst. Additional information is given in our advertisement columns.

——— The Asylums Committee of the London County Council invite tenders for the erection of fire alarm and telephone systems at their asylums at Banstead, Surrey, and Colney Hatch, London, N. Tenders by 12 o'clock, 30th inst.

——— The Manchester Town Council invite tenders for the laying of a system of underground telephone pipes, with inspection pits, service boxes, &c., in certain streets of the city. Tenders by *Tuesday next.*

——— The Queenstown Town Commissioners require tenders for the erection of works and the necessary plant for generating electric current for the public and private lighting of the town. Tenders by September 26th.

TENDERS ACCEPTED.—The Town Council have accepted the tender of Messrs. W. G. Higgs and Co., Glasgow, for wiring the municipal buildings, public library and police offices for the electric light. The amount of the tender is £280. 4s.

——— The Guardians of St. Giles's and Bloomsbury, London, W.C., have accepted the tender of the Brush Company for wiring and fitting up the electric light at the Board room and offices, for the sum of £45. 15s.

——— The Town Council of Taunton have accepted the tender of the British Thomson-Houston (Limited) for the supply of an alternator and a Willans engine for the sum of £1,058.

——— The Great Yarmouth Town Council have accepted the tender of the British Insulated Wire Company for the supply of cable for their electric light extensions for £1,031. 1s. Messrs. Crompton and Co.'s accepted tender for transformers was as follows :—1 kilowatt, £9 ; 2 ditto, £12. 15s. 6d. ; 5 ditto, £19s. 10s. ; 10 ditto, £31. 15s. ; 15 ditto, £42. 2s. 6d. ; and 25 ditto, £59. 11s.

——— The Selby District Council received 13 tenders for the erection of three lightning conductors at their waterworks, the prices ranging from 1s. 2d. to 2s. 8d. per foot. The tender of Messrs. W. Bowker and Co., of Huddersfield, has been accepted conditionally.

TENDERS RECEIVED.—The Hammersmith Vestry received 14 tenders for the erection of an electric light installation for public and private lighting. A tender from a Glasgow firm, received after the time appointed, is, it is stated, also to be considered.

SALE.—Our advertisement columns contain particulars of a quantity of electric lighting plant for sale by Messrs. Henry Lea and Thornbery, 38, Bennett's-hill, Birmingham. Included in the sale are three Elwell-Parker dynamos, three gas engines, switchboard and instruments, gas and exhaust pipes, shafting, &c.

APPOINTMENTS.—At the last meeting of the Hanley Town Council it was decided to appoint the assistant electrical engineers (Messrs. C. A. Cowell and C. J. Sutherland) joint electrical engineers and managers of the electricity works pending the further installation and during the expenditure of capital account thereon. Messrs. Cowell and Sutherland will be under the direction of the borough engineer (Mr. Joseph Lobley), and will each receive a salary of £150 per annum.

——— The Ayr Town Council have appointed Mr. E. G. Pink, who has superintended the laying of the mains, &c., borough electrical engineer at a salary of £200. Before going to Ayr Mr. Pink was engaged at the Dublin Corporation electricity works.

DISSOLUTION OF PARTNERSHIP.—Messrs. Beech and Welch, telegraph instrument case makers, of Dalston-lane, London, N.E., have dissolved partnership. The business will be carried on by Mr. Welch.

LIQUIDATION.—All claims against the Electric Trust (Limited) must be sent to Mr. F. Cross (the liquidator), 9, Bridge-street, Westminster, S.W., by October 14th.

BANKRUPTCY.—Mr. Edwin B. Lumb, of 85, Gracechurch-street, E.C., has been appointed the London trustee in the bankruptcy of G. F. Rogers, electrical engineer, of 5, Great Winchester-street, E.C., and 41, Maxilla-gardens, Notting Hill, W., London.

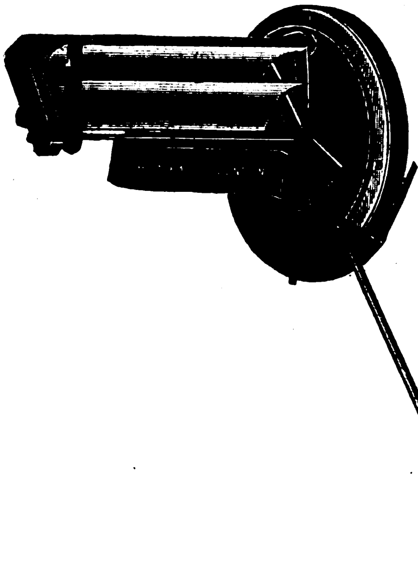
CITY OF LONDON ARC LAMP-POSTS.—The electric light posts throughout the City of London are now being recoated by Hartmann's paint, which has, the makers state, been selected for its durability and appearance, after exhaustive trials extending over two years. This material is supplied by Suter, Hartmann and Rahtjen's Composition Company (Limited), of Billiter-street, London, E.C.

REMOVAL.—Mr. Wilson Hartnell informs us that, having removed his works into larger premises, he is now transferring his offices to the same buildings at Volt Works, Kirkstall-road, Leeds, where all kinds of electrical engineering work and the manufacture of electrical machinery and apparatus will be undertaken.

Digitized by Google

CATALOGUE.—The sixth edition of Messrs. Nalder Bros. and Co.'s catalogue and price list is as replete as ever with matter calculated to delight the hearts of intending purchasers of electrical instruments. With a view of effecting a reduction in price and of facilitating "stocking," Messrs. Nalder Bros. have, where several forms of the same instrument have previously been made, specialised and developed only the pattern found by experience to be the most efficient. Amongst the numerous items of interest in this well-arranged catalogue we note Prof. Carhart's new form of Clark standard cell, which attains its E.M.F. according to temperature exceedingly rapidly, and has a coefficient of only 0·038 per cent. per degree. Other items in the list are a very compact, workmanlike type of d'Arsonval galvanometer; the N.C.S. lamp-stand and scale, a new and very neat design, allowing for a large range of height of mirror; the Ayrton-Mather universal shunt; the N.C.S. variable standard of self-induction, a compact and useful piece of apparatus; Prof. Unwin's extensometer (Messrs. Nalder Bros. are the sole authorised makers of this, and the inventor kindly undertakes to examine and certificate each instrument); the N.C.S. form of standard resistance, in which it is claimed that the temperature difficulty has been considerably diminished; standard manganin resistances of 100 ohms carrying 1 ampere; and Trotter's portable direct-reading photometer, embodying several recent improvements, by which both the candle-feet and the candle-power may be measured without calculation. Not the least praiseworthy features of this catalogue are its handy shape and its bold, clear type.

AN IMPROVED FORM OF AYRTON-MATHER ELECTROSTATIC VOLTMETER.—The accompanying illustration shows the working parts of



an Ayrton-Mather electrostatic voltmeter now being manufactured by Mr. R. W. Paul. In this instrument, as is well known, the conducting portions are shaped into parts of cylinders, the three fixed plates being firmly connected together, while the needle, consisting of curved aluminium plates, is drawn into the space between the fixed ones. The controlling force is gravity acting on a weight attached to the needle. The advantage of the curved form of plate is that it combines strength with lightness. Dead-beatness is secured by employing a copper sector, which balances the needle, and causing it to swing between the poles of a strong permanent magnet, the swings being damped by Foucault currents. The terminals are embedded in a block of ebonite, hinged to the case and provided with ebonite-headed screws, no metal parts being exposed to the touch.

DELAWARE HARD FIBRE COMPANY.—A recent issue of the *Electrical World* of New York states that a flourishing business is reported by the above Company from their works at Wilmington, Del., U.S.A., necessitating the works being in operation day and night, notwithstanding that the manufacturing plant has been doubled. One of the recent contracts secured by the Company is for furnishing the General Electric Company (U.S.A.) with fibre, and this order is of sufficient magnitude to give regular employment for some time to a large number of hands. Mr. J. Burns, who has the management of this Company's business in all parts of the world outside the North American Continent, reports a gratifying and almost unexpected increase of the business.

PRESENTATION.—Mr. J. L. Copping has resigned his position as Manager of the Acme and Immisch Electrical Works (Limited) to take a similar position with the Blackman Ventilating Company, of which, however, Mr. M. Shillito, the managing director, continues the active management. The Directors of the Acme and Immisch Company presented Mr. Copping with a case of cutlery, while the employés of the firm gave him a gold watch.

CABLE STORIES, ANECDOTES, &c.—Mr. Roland Belfort, of 14, St. Paul's-place, Canonbury, London, N., having undertaken to prepare a volume descriptive of the career of a cable man in the various branches of his profession, is anxious to collect anecdotes embodying any curious episodes, amusing adventures, extraordinary feats, &c., performed by men in the service. Mr. Belfort thinks it likely that many cable men could furnish him with photographs, anecdotes, &c., which would interest cable men all over the world, and he would therefore be grateful if such could be sent on to him, he, of course, acknowledging their receipt, and observing strict confidence where advised. Mr. Belfort is an old telegraph man, and his book should prove both instructive and amusing.

ABERDEEN.—The Watching and Lighting Committee of the Town Council have decided, on the recommendation of the borough electrical engineer (Mr. A. S. Blackman), to introduce in certain streets overhead lights suspended from wires lodged between standards on opposite sides of the thoroughfares. Should the experiment prove satisfactory it is anticipated that the arrangement will be extended.

ALSAGER (STOKE-ON-TRENT).—A meeting of ratepayers, presided over by Mr. Rigby (Chairman of the District Council), was held last week to consider the question of adopting a system of street lighting. It had been estimated that gas would cost £142 per annum, which would necessitate an increase in the rates of 3½d. in the £. A scheme of electric lighting, prepared for the Council by Mr. G. R. Peers, placed the cost of an installation for 1,200 8 c.p. lamps, including 40 street lamps, at £4,000. The annual cost of maintenance would be £618, while the revenue was estimated to show a profit of £82. As usual, the gas interest seems to have been well represented, and an animated debate took place, in the middle of which the Chairman adjourned the meeting for 12 months.

ARKLOW.—Recently a deputation of the Town Commissioners waited upon Mr. Arthur Chamberlain (chairman of G. Kynoch and Co., Limited) for the purpose of discussing the question of the introduction of the electric light into the town. Having heard the views of the deputation, Mr. Chamberlain said that Messrs. Kynoch and Co., in the near future, purposed lighting other portions of their premises by electricity, and when the additional plant had been put down they would then meet the Commissioners in any way they could, as they would then be able to supply electriccurrent at a much cheaper rate than they were in a position to do at present.

BATTERSEA.—It is stated that the Special Electric Lighting Committee have resolved, after careful consideration, to invite competitive schemes for lighting the parish by electricity, and to offer premiums for the three best. In the meantime application is to be made for a Provisional Order. The compulsory area, in which distributing mains are to be laid within two years, includes all the principal streets in the parish. The Committee have, however, decided to recommend that the dust destructor part of the original scheme be not proceeded with.

BERLIN EXHIBITION.—In reference to the "Trade Note" on this subject in our last issue, it is stated that Messrs. Siemens and Halske have obtained the contract for electrically equipping the various railways which will be constructed between the centre of the city and the Exhibition buildings in the Treptow Park. The contractors have obtained the privilege of using both overhead and underground systems.

BOOTLE.—At the meeting of the Town Council on Wednesday it was stated that the report of the Watch Committee on the electric lighting question would be presented to the Council shortly.

BRISTOL AND KINGSWOOD TRAMWAYS.—An experimental trip was made with one of the cars over the new electrically-equipped Kingswood line on Tuesday, and a further trial was made on Wednesday from the St. George depot. Both trials were made under the direction of Mr. Philip Dawson, and were, we understand, entirely satisfactory.

BURTON-ON-TRENT.—At the last meeting of the Town Council the Gas and Electric Light Committee reported that they had instructed their gasworks manager (Mr. F. L. Ramsden) to report as to the desirability of lighting those streets where the electric light mains are already laid by electricity.

CANTERBURY.—The Electric Lighting and Street Committee recently presented their report on the lighting of the city by electricity. The report, which was presented by Ald. Mason (Chairman of the Committee), states that from information obtained, through the surveyor, from various towns and districts where the electric light is installed, and after careful consideration of the whole question, the Committee are of opinion that the time has arrived for the introduction of the electric light in the city. The report also recommends that, before any scheme is adopted, the services of Mr. Robert Hammond be retained for the purpose of advising the Council and preparing an exhaustive report, at a fee not exceeding 50 guineas, this sum to merge in the usual engineering commission in the event of a scheme being adopted and works carried out.

CARDIFF EXHIBITION, 1896.—The metropolis of Wales is to have an Exhibition on a large scale in 1896. Owing to the intimate connection of the district with the coal and iron industries, the mining and engineering sections will, of course, be very prominent, and will doubtless prove the most attractive features of the show. Maritime industries are to be fully represented. As evidence of the leading position held by the port of Cardiff, the shipments of coal, coke, and patent fuel in 1894 amounted to no less than 15,316,165 tons. Other sections of the Exhibition will embrace latest developments in electricity, in scientific instruments, &c., whilst agriculture, horticulture, sports and pastimes are to be adequately catered for, the latter probably including a water show on a large scale. Representative men of all classes have the detail work in hand. Lord Windsor is president, Her Majesty the Queen is patron, and the Prince of Wales will be invited to open the Exhibition.

CHURCH LIGHTING.—In the September issue of the Windermere parish magazine the rector and churchwardens make an appeal for funds for lighting the church by electricity. The estimated cost of wiring, &c., is put at £75, and the appeal concludes: "During the winter months, when the church is heated and the gas also burning, the atmosphere becomes very close and stifling, and we are assured that many are hindered from attending the evening services on this account."——The Great Synagogue, London, E.C., will henceforth be lighted electrically. The work of wiring and fitting has been carried out by Messrs. D. Hulett and Co., and the total cost will exceed £300.——Wesley Church, Newport (Mon.) is to be wired and fitted for the electric light.

CHEADLE (STAFFS.).—The Parish Council have received an offer from Messrs. J. and N. Philips to light the public lamps by electricity. The firm have already erected a private electric lighting plant at their large tape manufactory, and are also able to supply current for the public lamps. The estimated annual cost would be £340 under a seven-years agreement, or £300 for a contract for 14 years. A parish meeting is to be held to discuss the matter.

COCOA FACTORY WORKED BY ELECTRICITY.—An extensive electric power and lighting plant is at present in course of erection at the factory of the well-known Dutch firm of Van Houten and Zoon at Weesp. The plant consists of three horizontal steam engines of 100 H.P. each, coupled direct to six 33 kilowatt four-pole dynamos. The distribution is on the three-wire system, and there are in all about 1,100 glow lamps, 285 arc lamps and one 30 H.P. motor.

CORK.—The Secretary to the Electric Lighting Committee has just presented an analysis of the replies received from the various town clerks of towns where the electric light is at present used. A meeting of the Committee was held on Tuesday, when it was decided to ask the Council to give them power to employ an electrical expert.

DEWSBURY.—At the last meeting of the Corporation Mr. Alderman Robinson expressed satisfaction at the fact that the consumption of gas had increased during the past year, notwithstanding the competition of the electric light. In answer to Mr. Birkhead, Mr. Robinson stated that the Gas Committee had decided to determine the agreement with Mr. Preece, their consulting electrical engineer.

DOVER.—We were in error in our Note last week in stating that the Town Council had decided to use incandescent gas lights for the next 12 months in Snargate-street, the Council at its meeting on the 27th refusing to rescind the agreement come to with the Dover Electricity Supply Company for lighting the street by arched arc lamps. The contract for incandescent gas lights was for other positions in the town.

EARLSTON (BERWICKSHIRE).—Recently a committee was appointed to consider the question of the purchase of the local gas works, but the scope of their inquiry has now been extended by adding thereto the question of the introduction of the electric light. Water power is available, and it is thought it would be more economical to establish electricity works than to purchase the gas works. The Committee are to consult with an electrical expert.

ELECTRIC TRACTION ON THE CONTINENT.—It is stated that the Union Elektricitäts Gesellschaft of Berlin has, in conjunction with the Austrian Landerbank, acquired the Linz tramways, and a system of electric traction is to be introduced. It is also reported that the same Company have received a concession to construct an underground electric railway from Brussels to the Bois de Tambre.

ELECTRICAL WATER INDICATOR.—The Weymouth Waterworks Company have instructed Mr. George Jennings, of Lambeth, S.E., to put up his patent electrical indicating and recording apparatus between the reservoir and the engine house at the waterworks. By this means the level of water from the reservoir will be shown in the engine house at all hours of the day and night. A similar apparatus is to be fixed at the Great Yarmouth Sewage Pumping Works.

EXHIBITIONS.—It has been decided to organise an exhibition of national Brazilian industries at Rio de Janeiro, and a commission is to be appointed to consider and report on the present customs tariffs, with a view to protectionist duties being imposed.

FIRE.—Messrs. Griffiths Bros. and Co., the well-known makers of non-conducting paints and varnishes, of Macks-road, Bermondsey, inform us that the fire which occurred at their works last week has in no way interfered with the business, the prompt action of the Fire Brigade having restricted the damage to one only of the buildings.

FIRE PREVENTION.—An International Fire Congress is to be held at Amsterdam from the 24th to the 28th inst., in order to give brigade officers, architects, engineers and insurance officers an opportunity to discuss every question connected with fire protection. This should prove a favourable opportunity to manufacturers of electric fire-call apparatus to place their systems before an important body of British and Continental fire experts.

THE FIRE AT THE CRITERION.—It has been stated that the electric light wires were suspected of having caused the recent fire at the Criterion Restaurant. We have authority for saying that "there is nothing whatever in the report of Messrs. Spiers and Pond's electrical engineer at the Criterion to show that the recent fire was due to electric light wires. There was no indication of any short-circuiting, and the electric lamps were all run on the evening prior to the fire."

FORT WILLIAM (INVERNESS-SHIRE).—It is stated that a company, with a share capital of £6,000, has been formed locally for the purpose of establishing works for the lighting of this town by electricity. The necessary power is to be obtained from turbines driven by the waters of the river Kinchnish, situate about two miles from Fort William.

GLASGOW.—At the last meeting of the Town Council the minutes of the Tramway Committee came up for confirmation. The question of the introduction of mechanical motors for the tramways had been remitted to a sub-committee for consideration and report. Treasurer and Gray in objecting to the appointment of this Committee, said the whole question had been carefully gone into two years ago, and they were then obliged to fall back on horse traction. They had found that the overhead electric system would cost £10,000 per mile double track, while the cable system would cost £20,000. They had spent £400,000 in purchasing horses, plant, &c., and before a penny had been returned to the Committee it was proposed to consider a new system. He held that no additional expense should be incurred until the existing method of traction had had a further trial. Mr. Walter Paton (convener) said the Committee thought the time had come when the question of applying mechanical motors to at least some sections of the line should be carefully considered. The minutes were approved by a large majority.

GREAT YARMOUTH.—The accounts of the electricity department for the month of August have just been published, and show a gross profit of £53. 8s. 11d.

HALIFAX.—The Town Council have decided to erect six arcs of 1,500 c.p. each in Crown and Silver-streets. Ornamental iron standards with curved top have been ordered for these lamps from Messrs. W. Macfarlane and Co., Glasgow.

HALSTEAD.—The question of the high price and inefficiency of the gas lighting is exciting some local feeling here just now. The Gas Company had been asked to make a reduction in the price of gas, but at the last meeting of the District Council the Company stated that no alteration could be made. The Public Lighting Committee recommend that only a temporary arrangement be entered into with the Company, and that they be empowered to make inquiries as to the cost of substituting electricity.

HASTINGS.—The Hastings and St. Leonards-on-Sea Electric Light Company have decided to make extensions to their mains in the Queen's-road.

INVERNESS.—The Caledonian Electric Supply Company (Limited) recently notified the Town Council of their intention to apply for a Provisional Electric Lighting Order for Inverness. The Company are to submit particulars of their scheme, and a special meeting of the Town Council will then be held to consider the matter.

KINGSTON-ON-THAMES.—The Lighting Committee of the Corporation have decided to adopt the "Brighton" method of charging for electric current from January 1st next.

LAMBETH (LONDON, S.E.).—A lengthy debate on the electric lighting question took place at the last meeting of the Vestry, when the several offers of the County of London and Brush Provincial Company and the Capital and Counties Electricity Company were discussed. The Lighting Committee brought up their report on the subject, and recommended the Vestry to notify both Companies that they (the Vestry) had no intention to proceed at present to put in operation their Electric Lighting Order. The adoption of this report having been moved, an amendment was proposed to the effect that, while the Vestry were not in possession of sufficient information to justify them in immediately proceeding to carry out the terms of their Order, they had no intention of surrendering it.

Digitized by Google

This truly heroic course was not only recommended in a lengthy speech by Mr. Everett, but was seconded by Mr. W. J. Hosking. Other members described the policy of the Vestry as "laying low and waiting." The Clerk to the Vestry pointed out that most probably, if the course recommended by the Committee were adopted, the Board of Trade might prove inquisitive as to what steps the Vestry were likely to take on the applications of the two companies. Mr. Alderman Hubbard tried hard—very hard—to bring the members to a sense of the importance of the subject by pointing out that other Vestries had adopted the electric light with apparently satisfactory results. He appealed to the members of the Lambeth Vestry to follow the examples set by St. Pancras, Islington, Hampstead, Shoreditch, Hammersmith and other London Local Authorities. He strongly advocated the Vestry taking the matter up and dealing with the electric light on behalf of their parishioners. Subsequent speakers referred pathetically to the general poverty of the district, and, if these gentlemen are to be credited, Lambeth is a very nice place to live out of. The result of the discussion was that the amendment was approved, and the report of the Committee, as amended, was adopted.

Llanelly.—Some time ago tenders for lighting a part of the town by electricity were obtained, and these were referred by the Estate Committee to the borough surveyor for consideration and report. At the last meeting of the Town Council the Committee submitted the surveyor's report, which stated that the three most suitable tenders were those of the Electric Construction Company (Limited), Messrs. Siemens Bros. and Co. (Limited) (No. 2 scheme), and Messrs. J. C. Howell (Limited). The Committee further reported that the establishment of electric light works would involve an expenditure of about £10,000. After a protracted but incoherent discussion it was decided not to proceed with the matter.

Middleton (Lancs.).—The Town Council have decided to apply for a Provisional Electric Lighting Order.

Portsmouth.—The Electric Lighting Committee has received 25 applications for the position of overseer to superintend the laying of mains, &c., in connection with the electric light extensions. The Chairman was empowered to appoint the most suitable of the following four candidates to the post:—Messrs. A. F. Evans (Wolverhampton), J. A. Dixon (Margate), W. Fowle (London), and N. Staniland (Douglas, Isle of Man).

Reduction in Telegraph Rates.—The Eastern Telegraph Company announced that rates to the following places are reduced: To Pernambuco, to 3s. 6d. per word; other places in Brazil, Argentina, Uruguay and Paraguay, to 4s. 6d. per word. Similar reductions are announced by the Anglo-American and the Direct United States Companies, so far as they relate to messages from Great Britain to Argentina, Uruguay, and Paraguay.

Rotterdam.—Six electric cranes are to be erected on the new quays which are to be built in connection with the Rhine Harbour. The cranes must be capable of lifting four tons and of reaching across three sets of rails, thus allowing the processes of loading and discharging being simultaneously performed. It is also stated that, though the town has been in possession of electricity works for some time, but scant use is made of the current for private lighting. On the other hand, electricity is being applied to the cranes at the docks and quays on the left bank of the river, and loading and discharging can be performed at night by means of the electric ilght.

Runcorn.—The question of the introduction of the electric light into the town will be discussed at the next meeting of the Town Council.

Sacriston (Durham).—The Parish Council have decided to light their township, which comprises Sacriston, Witton Gilbert and Daisy Hill, by electricity. The Newcastle branch of the Corlett Electrical Engineering Company has obtained the contract for plant, &c.

Sheffield.—The Town Council have decided to expend £2,000 upon electric light fittings, &c., for their new municipal buildings.

Swansea.—The Town Council will consider at their next meeting a scheme for lighting the main streets of the town by electricity. The cost of the installation is estimated at about £56,000. The Electric Lighting Committee have had the subject before them for some years, and have at last proposed a complete scheme for the Council's consideration. The Corporation's Provisional Order was obtained in August, 1889, and in 1890 serious steps were taken with the object of carrying the Order into effect. Tenders were invited, and it was proposed to grant a concession to the contractor who should be appointed to put down plant for the installation. Ultimately, however, it was decided to abandon this plan and to await further developments of electrical enterprise. The subject which has really brought the electric lighting question once more to the front is the serious matter of the disposal of town refuse, and in January, 1894, the Committee took counsel with Mr. E. Manville, who was instructed to prepare a combined electric lighting and refuse destructor scheme. In connection with the proposed electric works Mr. Manville's report was presented in June, 1894, and was in favour of a combined scheme. The Committee have been considering this report, and have now come to the unanimous conclusion that a high-tension alternating current system would best suit the requirements of the town. The Committee's report concludes with recommendations to the effect that Mr. Manville's scheme be approved, and that application be made to the Local Government Board for powers to borrow £60,000 for electric lighting and refuse destructor purposes.

Telegraphic Delays.—The Glasgow Chamber of Commerce has resolved to petition the Postmaster-General respecting the time taken in telegraphing between Glasgow and London. This petition is to be supported by a similar one from the Glasgow Royal Exchange. It is complained that the lowest average time is 30 minutes and the longest 65 minutes, which is very reasonably considered excessive.

Torquay.—The report of the Electric Lighting Committee on the question of the electric lighting of the town is nearly ready, and will be submitted at the next meeting of the Council.

Walsall.—The electricity works are now in a forward state, and it is anticipated that current will be available at the commencement of next month.

Wellington (New Zealand).—The Town Council have adopted the recommendation of the Electric Lighting Committee to rescind their present contract with the New Zealand Electrical Syndicate for lighting the streets, at £3. 10s. per lamp, and to enter into a new arrangement whereby the Syndicate are to supply electric current at £4. 10s. per lamp. This step has been taken owing to the unsatisfactory state of the water supply of the town, and under the new arrangement the water at present utilised by the New Zealand Syndicate will be available for town purposes.

Worcester.—At the last meeting of the City Council it was decided to accept the Brush Company's offer to supply and fix two 36-kilowatt transformers for the waterworks motors in lieu of the 30-kilowatt transformers originally supplied, at £25, on condition that the Company give a written guarantee that the larger transformers will be sufficient for the purpose, and that they will maintain them in good working order for two years without charge.

Wolverhampton.—A Local Government Board inquiry is to be held into the application of the Corporation for powers to borrow an additional £5,000 for electric lighting purposes.

Worksop.—The District Council are dissatisfied with the way in which the local gas company are carrying out their contract for the public lighting, and at their last meeting several members expressed themselves favourable to the introduction of the electric light. It was stated that a company was being formed for the purpose of lighting the town by electricity. Eventually the whole matter was referred to the Lighting and Paving Committee.

Yeadon (Yorks.).—A meeting of ratepayers is to be called for the purpose of considering the lighting of this district by electricity.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by Mr. J. C. Chapman, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

August 26, 1895.

16,008. G. Dillberg and P. Rabbidge. London. An improved telephonic instrument designed for use on poorly-insulated lines, such as the existing wires of an ordinary wire fence.*

16,019. J. Y. Johnson. London. Improvements in connection with incandescent lamps and their holders and fittings. (A. Swan, United States.)

August 27, 1895.

16,022. E. Burnet and F. F. Smith. Wigan. An improved form of cell for primary or secondary electric batteries.

16,042. H. D. Norman. Brighton. A compound electrical testing switch.

16,077. W. P. Thompson. London. Improvements in electromagnetic tools. (A. G. Fonda, United States.)*

August 28, 1895.

16,173. C. S. Newman. London. A switch formed as a handle, in which electric circuit is completed by the automatic fall of a piece of solid metal contained within the handle.

August 29, 1895.

16,218. J. R. Shearer. London. Improvements in electrical fire and burglar alarms.

16,247. H. Edmunds. London. Improvements in or connected with electric cables or conductors.

16,248. H. Edmunds. London. Improvements in electric transformers, and dynamo armatures.

August 30, 1895.

16,275. J. Finlayson. Glasgow. Improvements in instruments for making electrical and magnetic measurements.

16,287. L. Hallé. London, Improvements in dynamo-electric machines and motors.*

SPECIFICATIONS PUBLISHED.

Note.—All Specifications can now be obtained at the uniform price of 8d. each.

1894.

21,045. Hutin and Leblanc. Dynamo electric machines.

1895.

4,873. Wiggins, T. P. and G. H. Electrical insulating materials.
12,469. Müller. Electric railway vehicles.
12,772. Rowand. Electric circuits.
12,836. Dorman and Smith. Electric cut-outs.
12,954. Chloride Electrical Storage Syndicate (Limited) and Grindle. Secondary batteries.
13,207. Seibold and others. Arc lamps.

COMPANIES' MEETINGS.

Electric Construction Company (Limited).

The second annual general meeting of this Company was held at Winchester House, Old Broad-street, London, yesterday (Thursday), Sir Daniel Cooper, Bart., G.C.M.G., presiding.

The SECRETARY (Mr. James Gray) read the notice calling the meeting, the report of the Directors and statement of accounts being taken as read.

The CHAIRMAN said: Gentlemen,—The report and accounts, of which I am to move the approval, if not so satisfactory as we could wish them to be, show a considerable improvement as compared with those submitted to you last year, and they give good promise for the future, for the manufacturing profit this year amounts to £31,814. 12s. 7d., against £25,754. 10s. 5d. last year. The net profit of £12,091. 10s. 3d. we recommend should be appropriated in payment of the full Preference dividend, and the balance of £10,134. 15s. 10d. carried forward to the credit of next year's accounts. The profit has all been fairly and hardly earned, and might properly be applied in payment of a dividend on the Ordinary shares, but our available capital is barely adequate for the development of our business, and at the same time to do justice to the debentures and shares in other companies we inherited as a legacy from the old Corporation. This is the sole reason that moved the Directors to the conclusion that it would be for the advantage of the Company and ultimately in the interest of the shareholders to make no distribution of dividend at present. Some of us are amongst the largest shareholders, and no doubt would be greatly pleased to have a dividend, not merely for the sake of the money, but from the credit arising from the paying of a dividend, but we are satisfied that in the long run it will be more to our credit as Directors and advantage as shareholders to build up the business on broad, solid foundations. We ask you to have a little further patience and we are emboldened to do so by feeling confident that your forbearance will meet a due reward. The accounts seem clear and explicit, as we intend them to be, but I will invite your attention to those items which specially indicate the position and progress of the Company. If any shareholder desires further information, we will be happy to give it. Dealing first with the profit and loss account, you will note with satisfaction that we have reduced the working expenses fully £2,000. We may be able to make some further reduction, but with due regard to efficiency any further reduction can hardly be important. Our hopes of further improvement are in the direction of greater efficiency—that is, in getting better results from our expenditure. You have no doubt observed that, besides maintaining and renewing plant and buildings, the depreciation account has been credited with £5,000 out of revenue, as compared with £3,000 last year. Some of you may think that we have been rather too free in taking so large a sum out of the revenue of the year, and perhaps there may be some justification for that view; but we prefer to err, if we do err, on the safe side. We do not fix £5,000 as the amount to be appropriated to depreciation every year. After some experience, we may find that if we maintain the buildings and plant in good order and condition, and replace any tools worn out from revenue account, the allowance for depreciation may be reduced; but for the present we think £5,000 is the proper sum to be charged against revenue in this respect. Turning to the credit side of the account, the gross manufacturing profit amounts to £31,814. 12s. 7d., over £6,000 more than last year, which seems to me a very gratifying improvement in these days of trade depression and keen competition. Such profits in the circumstances seem to me strong evidence of the remunerative character of the business in which our Company is engaged. Coming now to the balance-sheet, the various liabilities explain themselves, and do not seem to call for any comment. On the assets side of the account, you will observe that £1,940. 2s. 6d. has been added to the property account for additions to plant and buildings during the year. This sum has not been expended in replacing worn out tools, but for actual additions to our plant and buildings which will enable us to turn out more work, and is thus an expenditure properly chargeable to capital. You will also note that the old property of the Company in Commercial-road, Wolverhampton, has been sold. The price obtained for the property (£2,500) has been handed over to the trustees of the First Mortgage Debentures, and has been invested by them, for the benefit of the debenture-holders. There is little change on the account "Shares and debentures in other companies." This account, as you are aware, consists of various securities taken over from the old Corporation. No interest has been charged to this account. Some small securities have been sold and a considerable amount of new added, chiefly the result of obligations of the old Corporation, and the total debit remains practically the same as last year. We consider this asset on the whole improved in value, and believe that as the various undertakings develop, the amount at debit of the account will be fully realised. I have now done with the accounts, and will refer to some matters of general import. The installations completed during the year have been entirely successful, and confirm the high reputation of the Company for first class work. Amongst the more important works in hand are the large lighting installation at Clerkenwell expected to be completed within the next two or three months, and the electrical equipment of the Hartlepool tramways which we hope to have in operation about the beginning of next year. I believe there is a great future for electric traction, and if so, those who succeed in solving the initial difficulties in the practical application of the new power may be expected to have the lead in the business. I am very confident that the electrical equipment of the Hartlepool tramways on the plans designed by our manager, Mr. Blackburn, will prove successful, not only from an engineering point of view but also in an economic and financial aspect, and lead the way to an important extension of business in this direction. The Directors are very pleased to be able to report that their relations with the workmen at Bushbury are of a highly satisfactory character. Now that the works are completely organised under the supervision of our manager, Mr. Blackburn, and the most competent staff that can be had, the outturn of work is increasing, and its quality fully maintains our previous high reputation for skill and workmanship in our manufactures. Perhaps the best evidence of this is that we are full of orders for the next six months. With our high reputation, orders in hand for six months, and improved trade prospects, you will naturally inquire why in these circumstances we do not raise prices, so as to be able to pay you at least a moderate dividend. Well, gentlemen, that is the conclusion at which the Directors have arrived, and we are now intimating a moderate advance in prices, such as is fully justified by the advance in materials and the improved prospects of trade. I believe that with electrical plant it will be found even more certain than in the case of other machinery that the best is the cheapest, and that the experience of those who are beginning to use electrical machinery will convince them that the best article is, in the long run, the most economical. Our prices will compare with those of other makers of first-class machinery, but we prefer to compete rather in quality than in cheapness, and decline to sacrifice quality for cheapness. Much advantage cannot be expected from the new prices during the first half of the year, because the interests of our customers have to be considered; the benefit will accrue later on. I have only to add that the general position of the Company has materially improved during the year, and I fully expect we will be able to submit to you next year a report and accounts showing still greater improvement. For myself, speaking as one largely interested in the Company, I have now more confidence in its management and in the profitable character of its business when prudently and carefully conducted than at any previous period of its existence. With these remarks I beg to move:—

"*That the accounts and the report and the recommendations therein contained now submitted by the Directors be approved and adopted.*"

Mr. JAMES WILLIAM BARCLAY (Deputy-Chairman) seconded the motion.

Dr. DRYSDALE asked whether it was proposed that the substitution at Hartlepool of electric traction for the steam power formerly in use should be in the form of overhead traction or an underground system.

Mr. BARCLAY said that the Hartlepool tramways were originally steam tramways, but in consequence of the excessive cost of that kind of propulsion it had been abandoned, and the Electric Construction Company was to provide an electrical equipment on the overhead system similar to that of the South Staffordshire Tramways, which was equipped by them, the only difference being that there would be considerable improvements made in the case of Hartlepool. Their manager hoped to be able to show that electric traction for tramways was a success not only from an engineering but from an economic point of view.

Dr. DALE asked for some information regarding the litigation between the Company and the South Staffordshire Tramways Company, and suggested whether some compromise could not be arrived at.

The DEPUTY-CHAIRMAN replied that there had been a suit going on between the Companies respecting the original contract; but meanwhile this Company were running the tramways under an agreement at so much per mile, which was satisfactory, yielding them, as it did, a fair return on the capital invested. They might be sure that the Directors of the Company were anxious to come to an amicable settlement.

The CHAIRMAN said that the Board did not spend a shilling in law if they could possibly avoid it, and when they did take legal advice they always took the best.

The resolution was put to the meeting and carried unanimously.

The CHAIRMAN then moved the re-election of Messrs. James W. Barclay and J. Irving Courtenay to their seats at the Board, and paid a warm tribute to those gentlemen for the zeal and ability which they bring to bear in the conduct of the Company's business.

Mr. PHILIP EDWARD BEACHCROFT seconded the motion, which was carried *nem. con.*

On the motion of Dr. DRYSDALE, seconded by another SHAREHOLDER, the auditors, Messrs. James Meston and Co., were re-appointed.

Dr. DRYSDALE afterwards moved a vote of thanks to the Chairman and Directors. He referred in terms of satisfaction to the state of the Company's works at Bushbury, Wolverhampton, which he had personally inspected.

A SHAREHOLDER seconded the resolution, which was carried unanimously; and

The CHAIRMAN having expressed his acknowledgment, the proceedings ended.

NEW COMPANIES, STATUTORY RETURNS, &c.

ELLIOTT'S MOULDING AND JOINERY COMPANY (LIMITED).—This Company has been formed with a capital of £30,000, in £1 shares, to take over the business of Samuel Elliott, maker of electric light wire casings, timber merchant, &c., at Newbury, Berks.

INCORPORATED SOCIETY OF SCIENCE, LETTERS AND ART (LIMITED).—This Society has been registered, with a capital of £2,000, in £1 shares, to acquire an undertaking styled "The Society of Science, Letters and Art of London," and to carry on and extend the operations of the same.

PIONEER SYNDICATE OF THE CAPITAL AND COUNTIES ELECTRICITY SUPPLY COMPANY (LIMITED)—This Company was registered on September 3rd with a nominal capital of £5,000, in shares of £1 each, to generate, produce, store, accumulate and distribute electricity, electromotive force, or other similar agency, for the purpose of lighting public or private buildings, mines, ships, &c., to acquire the right to use or manufacture and put up telephones, telegraphs, electric bells, phonographs, and all kinds of electrical apparatus, and to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity and manufacturers of and dealers in electrical and scientific apparatus. The first subscribers, with one share each, are: P. Greville, electrician; F. Wright, C. E. Easterman, engineer; C. F. Croll, E. Mann, J. L. Higgs, and Stephen Sellon, civil engineer.

WESTRALIAN ELECTRIC LIGHTING AND SUPPLY COMPANY (LTD.).—This Company was registered on September 3rd, with a capital of £80,000, in shares of £1 each, to enter into an agreement with Westralia (Limited) to generate, produce, store, accumulate and distribute electricity, electromotive force, or other similar agency, for the purpose of lighting public and private buildings, manufactories, mines, public streets, omnibuses, tramcars, cabs, and other vehicles, ships, lighthouses, railways, and other places and things, or for plating, combining, separating, or otherwise working in metals; to carry on the business of electricians, mechanical engineers, suppliers of electricity, electrical apparatus manufacturers and dealers, &c., and to construct, establish, maintain and carry on, in Western Australia or elsewhere, electric lighting works and stations, railways, tramways, and waterways. The subscribers, with one share each, are: A. Marks, G. Mellors, R. A. Webster, L. Bulger, B. O. C. Orlebar, F. A. Thompson, mining engineer, and J. G. Macintosh.

BRITISH THOMSON-HOUSTON (LIMITED.).—The annual return to July 18th has been filed. Out of a nominal capital of £100,000, in £10 shares, 7,649 have been taken up, and £4,175 have been issued as fully paid. The full amount has been called on 3,081, £7. 10s. per share on 237, £5 per share on 106, and £2. 10s. per share on the remaining 50.

DIXON AND CORBITT AND R. S. NEWALL AND COMPANY (LIMITED).—The annual return to August 21st has been filed. The nominal capital is £120,000, in 6,000 Preference and 6,000 Ordinary shares of £10 each. The whole of the Ordinary and 1,957 Preference shares have been taken up, and the Ordinary and 250 Preference shares have been issued as fully paid. £8 per share has been called on the remaining 1,707 Preference shares.

ELECTRICAL COMPANY (LIMITED).—The annual return was recently filed. The whole nominal capital of £15,000, in £5 shares, has been issued, with £3 considered as paid, and £1 additional has since been called.

ELECTRIC MOTIVE POWER COMPANY (LIMITED).—The annual return has been filed. Of a nominal capital of £20,000, in 10,350 Preference and 9,650 Ordinary shares of £1 each, 754 Preference and all the Ordinary shares have been taken up. The latter have been issued as fully paid, and the full amount has been called on the Preference shares.

ELECTRIC POWER STORAGE COMPANY (LIMITED).—The annual return to August 15th has been filed. The nominal capital of £100,500 is divided into 20,000 Ordinary shares and 100 Founders' shares of £5 each; 18,257 of the former and 66 of the latter have been taken up, and 15,120 of the Ordinary have been issued as fully paid; £3 per share has been called on the remaining 3,137 Ordinary, and the full amount has been called on the Founders' shares: £400 has been paid in respect of 400 Ordinary and four Founders' shares forfeited.

ELECTRICITY SUPPLY COMPANY FOR SPAIN (LIMITED).—The annual return to May 14th was recently filed. The nominal capital is £100,000, divided into 19,000 Ordinary and 100 Founders' shares of £5 each. All the shares have been taken up. The Founders' shares have been issued as fully paid, while the full amount has been called on the Ordinary shares.

LANCASHIRE ELECTRIC AND ENGINEERING COMPANY (LIMITED).—In reply to requests for the filing of the returns, the Secretary (Mr. F. W. Briscoe) states that the business has been transferred to another company, and the concern has, therefore, been allowed to lapse.

SHROPSHIRE ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual returns for 1894 and 1895 were recently filed. The nominal capital is £25,100, in 2,500 £10 Ordinary shares and 100 Founders' £1 shares; 275 of the former and 44 of the latter were taken up, and £2. 5s. per share has been called on the Ordinary shares.

TELAUTOGRAPH COMPANY (LIMITED).—An agreement with the Gray European Telautograph of Chicago (incorporated in Illinois, U.S.A.) provides for the sale to this Company of certain British patents (11,032 of 1888, 17,965 of 1891, 2,696 of 1873, and 10,171 of 1894), granted to Elisha Gray, and 12,617 and 15,577 of 1886, 1,527 and 16,378 of 1887, and 1,988 of 1891, granted to T. O'Brien and assigned to F. W. Cushing. The consideration for the sale is £6,000 in cash and the allotment of 26,000 fully-paid shares (1 to 26,000) of £1 each.

THOMAS PARKER (LIMITED).—The annual return to August 14th has been filed. Of a nominal capital of £75,000, in £10 shares, 5,087 shares have been taken up, and of these 1,750 have been issued as fully paid. £8 per share has been called on the remaining 3,337 shares.

CITY NOTES.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver, 30$\frac{5}{16}$d. per oz. (Sept. 12th). Consols (2¾ per cent.) 107¾—107⅞ for money, 107¾—107⅞ for account (Sept. 12th); 2½ per cent. 106¼—106½. Stock Exchange Settling Days: Consols, Oct. 1st; Stocks and Shares Continuation Day, Sept. 25th; Ticket Day, Sept. 26th; Pay Day, Sept. 27th; Mining Shares Carry-over Day, Sept. 24th.

BABCOCK AND WILCOX (LIMITED).—The fourth ordinary general meeting of this Company was held on Tuesday at 147, Queen Victoria-street, E.C. The Chairman (Mr. Andrew Stewart) said they proposed to pay for the half-year ended June 30th last a dividend at the rate of 6 per cent. on the Preference and 7½ per cent. on the Ordinary shares, making, with the interim dividend paid in December last, 12½ per cent. on the Ordinary shares for the year; £10,000 was placed to reserve and a balance of £4,830. 17s. carried forward. During the past year the Company had enjoyed continued prosperity, and their prospects for the present were fairly good. In conclusion, the Chairman referred to the many improvements that had been made in their boiler and to various patents that had been taken out in connection therewith. The works and plant were being kept up in a most efficient condition, and new plant had been added with a view to work more economically in the future. The report and accounts were adopted.

BRIGHTON AND ROTTINGDEAN SEASHORE ELECTRIC TRAMROAD COMPANY (LIMITED).—A meeting of the shareholders of this Company was held on the 30th ult. at the offices, Madeira-road, Brighton, when a resolution authorising the issue of £5,000 in debentures was passed. The Chairman (Mr. E. G. Bleackley) stated that the line would be completed and ready for traffic by the beginning of next summer. The Company continue to make complaints of the measures taken by the Brighton Corporation to delay the completion of the work, but the Corporation justify their position by urging that deviations from the original plans have been made by the Company.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended September 8th amounted to £839, against £840 in the corresponding week of 1894, a decrease of £1. The total receipts for the half-year are £8,509, against £8,576 for the corresponding period of 1894, a decrease of £67.

DOVER GAS COMPANY (LIMITED).—At the annual meeting of this Company, on Monday, the Chairman (Mr. W. Mannering) reported that there had been an increase in the quantity of gas sold during the past year of 10¾ per cent., and he thought they would be able to hold their own against the electric light company by means of incandescent gas lamps. Mr. Mowll even thought the electric light would directly benefit them, as wherever the electric light was introduced adjoining shopkeepers would be compelled to have a better class of gas illumination. Mr. Mowll was on safe ground.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 8th inst. amounted to £1,324. The amount for the corresponding week last year was £1,054; increase, £270.

SHEFFIELD UNITED GAS LIGHT COMPANY (LIMITED).—At the half-yearly meeting of the shareholders of this Company, on Tuesday, the Chairman (Sir F. Mappin, M.P.), said he was a firm believer in the prospects of well-managed gas companies. He thought they had not much to fear from the electric light, and quoted certain figures as to the comparative cost of gas and electricity in support of this view. Some of the shareholders were not, however, quite so sure that the electric light would not affect their dividend of 10 per cent., as Mr. John Wilson said the Directors ought to reduce the price of gas by 2d. per 1,000 cubic feet, and thus "knock out" the electric light. He was afraid the electric light might reach them in time unless it were kept back by such a reduction.

STOCK EXCHANGE PRICES.—A correspondent of the *Financial News*, who signs himself "A Shareholder in Both Companies," points out the difference in the prices of the shares of the Edison and Swan United Electric Light Company and the National Telephone Company, of both of which Mr. J. Staats Forbes is chairman. "The former has recently distributed a dividend of 5 per cent. on the Cumulative Preference shares for the year, and, after paying the interest on the £100,000 Four and a-Half per Cent. Debentures, a sum of £3,782 has been carried forward. These £5 shares, £3 paid, are quoted in the Official List at 2 to 2½, while the Ordinary £5 shares of the National Telephone Company stand at 6¼. This means that an investor gets about 6½ per cent. interest for the former, as against 4 per cent. in the National Company."

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended September 6th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were to £3,026.

WESTERN UNION TELEGRAPH COMPANY.—The Directors of this Company have declared the usual quarterly dividend of 1¼ per cent. The accounts for the quarter ending 30th inst. show an estimated net revenue of $1,850,000, or a surplus, after providing for the dividend, of $414,555, and a total book surplus of $7,862,031.

WESTRALIAN ELECTRIC LIGHTING AND SUPPLY COMPANY (LIMITED). This Company has been formed for the purpose of acquiring the concession for the exclusive right of furnishing electric light to the municipality of Coolgardie (Western Australia) for 21 years from Westralia (Limited). The nominal capital of the Company is £80,000, in £1 shares, of which £35,000 are working capital. The shareholders in Westralia (Limited) may apply for a portion of the shares at par.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 905. [No. 21. Vol. XXXV.] FRIDAY, SEPTEMBER 20, 1895. PRICE SIXPENCE.

NOTES.

At the last meeting of Section A on Wednesday, the long-looked-for Report of the Committee on Electrical Standards, with its important Appendix by Dr. Oliver Lodge, on "Magnetic Units," was brought forward. The Report itself, though undeniably useful, is as dry as a mere list of figures of a year's work in testing resistance coils could make it. But in the Appendix there is matter of far-reaching interest. Long wallowing in the mire of empiricism, the result of a mistaken step at the outset of its career, the science of magnetic measurement has made one more effort to get its feet on to firm ground. Of the success which may attend this latest struggle towards an emancipation from empiricism it is not yet time to speak; and our readers will be better able to judge for themselves, when they have read the report of the discussion, which we hope to publish next week. Suffice it now to say that three main suggestions were made by the Committee; suggestions, it must be remarked—not cast-iron dictatorial laws. The humility with which they were brought forward enhances their claim to international consideration. The three suggested additions to the nomenclature of magnetic science were :—

(1) That as a unit of magnetic field 10^8 C.G.S. lines be called a *weber*.

Note.—A *weber* added per second at a steady rate to the field girdled by a wire circuit induces one volt in every turn of that circuit.

(2) That the C.G.S. unit of magnetic potential or magnetomotive force be called a *gauss*.

Note.—An ampere-turn corresponds to $\frac{4\pi}{10}$ (or 1·2566) *gauss*. Hence the number of *gauss* round any closed curve linked on an electric circuit is equal to $\frac{4\pi}{10}$ times the number of ampere-turns in the circuit.

(3) That the termination *-ance* be used in general for words expressing the properties of a definite body or piece of matter; *e.g.*, resistance, conductance, inductance, permeance, &c. And that the termination *-ivity* or *-ility* or the like be used for words expressing the specific properties of a material; *e.g.*, conductivity, resistivity, inductivity, refractivity, permeability, &c.

The most striking criticism of these proposals is that made by Prof. Silvanus Thompson, who pointed out that the term *weber* had already been adopted in America for the C.G.S. unit of flux—viz., one *line*. And, though he agreed with the proposal to name the C.G.S. unit of magnetic potential the *gauss*, he mentioned that the term *gilbert* had been proposed by the American Institute of Electrical Engineers for that which it is here proposed to call the *gauss*; while *gauss* itself suggests in American language the unit of magnetic flux density. Whether such clashing between the usages in the two countries is or is not liable to lead to confusion, our readers will not need our assistance to enable them to judge. Another important point lies in the fact that no dynamo yet built has a total magnetic flux so large as one *weber*; the consequence being that only fractions—often very small fractions—of one *weber* would be spoken of in practice. In concluding his remarks, Prof. Thompson called attention to that system of magnetic units which alone, of all systems, deserves to be called rational—namely, that proposed by Mr. Oliver Heaviside. The opinions of the speakers in the discussion were divided in regard to the practicability of adopting this system now; many feared that it was too late for so radical a change; others thought the change could be made in 30 or 40 years; while some were disposed to regard the revolution as being within the range of present possibilities, and as far less difficult a task than the revolution of a system of weights and measures, or the shifting of the standard meridian of commercial and scientific time in any country.

The cry of "Organise! organise!" is becoming almost as frequent in electrical as in electoral circles, and in face of the unqualified assertions of Lord Kelvin, Lord Rayleigh, Prof. Lodge, and others, good organisation would seem to be as much a matter of supreme importance in the one case as in the other. That being so, the Ipswich meeting of the British Association will have made a name for itself, if the Committee which was appointed after the reading of Sir Douglas Galton's Memorandum on the Reichsanstalt contributes in any appreciable way to the better organisation of English research work. As Prof. Lodge pointed out, it is not that we have not the men, nor that we lack the money; but it is that each separate man separately doing what is right in his own eyes results in a terrible lack of coherence. The elementary filaments of research require to be centralised and brought into perfectly systematic relationship with a head-quarter. But in what particular manner is this to be done? Some are inclined to think that the one and only solution of the difficulty lies in sacrificing much of our liberty of research at the shrine of the State exchequer; receiving, in return for our present right to research just what, where, when and how we individually please, the money and that amount of departmental contro

Digitized by Google

which are necessary to enable us to research co-ordinately and in concert. If ever such a sorry state of affairs should come about, scientists are likely to find themselves in a position analogous to that of a research expert in the employ of a manufacturing company. They will be tolerated, in their investigations, only in so far as there is a prospect of the results becoming commercially and nationally useful. The idiosyncracies of a D line in the spectrum of a remote and obscure nebula will scarcely meet with the same degree of State patronage as an organic compound possessing fifty times the explosive power of cordite, or armour plating surpassing the stoutest harveyised steel. Prof. Ayrton is perfectly right when he says that scientific research stands no chance of the State aid which he and others so much desire, until it shall have shown itself to be of as great national importance as the building of warships.

Mr. Earle is to be congratulated on the great amount of information respecting storage batteries which he has compressed into the Paper on the subject which he read before the British Association at Ipswich. His remarks on the manner in which specifications for storage batteries are too often drawn up will, we hope, lead to some more uniform practice being adopted in the future than exists at present. There are many other points of interest in the Paper, both from the commercial and from the scientific point of view, but we can only call attention to one of them here, namely, the effect of the electrolyte. The author's notes on the influence of varying strengths of acid on the behaviour of cells are extremely interesting, and seem to endorse a view put forward some years ago, that it was the nature of the electrolyte employed, and the treatment which cells received *after* they left the hands of the manufacturers which mainly influenced their behaviour, for the author points out that each special type of plate has a particular strength of acid solution with which it works best. With reference to the discussion as to the influence of persulphuric acid, it is noticeable that with about 1·250 acid we get the best results both as regards capacity and voltage. Now this strength of acid also gives us nearly the best conditions for the formation of persulphuric acid, which again decreases as the strength of acid is increased, nearly ceasing at 1·500, this strength of acid also giving the minimum capacity in the case of the cells. Mr. Earle has on this occasion confined himself to a narration of facts observed in practice, and to the physical properties of the electrolyte employed; but we hope that he may extend his researches to the nature of the chemical reactions which occur in the electrolyte in storage batteries, and to the effect of change of density on these.

The view held by many, that the slow telephonic development of England is not by any means solely due to high rates and bad management, is in a large measure borne out by the valuable table published by Mr. A. R. Bennett in his British Association Paper. Five of the six lucky countries that obtain first prizes at his hands are agricultural and more or less wild. From the poverty and sparse population of the countries in receipt of Mr. Bennett's telephonic eulogies, we indeed at first concluded that he was really aiming at establishing some connection between the existence of excellent telephonic facilities and a lack of wealth and natural resources. We should certainly like to see the telephone used rurally as much as it is, say, in Norway, but we cannot help thinking that the main reason the telephone has flourished there so exceedingly is because it came into a country without an elaborate telegraphic network such as our's and where other circumstances apart from tariffs favoured it.

Although huge water-power plants such as the one at Niagara Falls, and ambitious water-power projects such as those we hear of almost daily from places as far apart as the Rhone, California and South Africa, are calculated to rivet the attention of the public and to inspire the social dreamer with visions of a regenerated, or at any rate physically cleaner, industrial community, modest little plants like the one recently laid down at the Ontario and Daly Mines in Utah give perhaps a clearer insight into the important economies and improvements immediately realisable by the electrical utilisation of waste water power. As will be seen from Mr. McKay's article, reprinted in another column, these mines were in danger on the one hand of financial submersion, if the works necessary to keep down the water were undertaken, and on the other of actual aqueous submersion unless something was done to get rid of the intruding fluid. In the end, a three-mile long drain tunnel was run, and when nearing completion the brilliant idea occurred of electrically utilising the energy of the 120ft. fall at its mouth. To-day, current is being transmitted a distance of 6½ miles, and the plant, which is looked after by two men, annually saves its owners £600 in fuel and illuminating oil, and earns a trifle besides; and before many more months are passed its capacity will be doubled, and it will be earning a handsome profit. Now, we have no wish to unduly decry other methods of power transmission, but where the circumstances are such as those just described, electricity, and electricity alone, holds the field. In this country this particular field of utility is unfortunately a very restricted one indeed; abroad it is otherwise, and we are hastening on to many unexpected developments.

Cable Interruption and Repairs:—

	Date of Interruption.
Aden-Zanzibar	September 2, 1895.

Electric Heating for Electric Cars.—The American Electric Heating Company has an order to equip with electric heaters, by November 1st, 750 of the 889 electric cars belonging to the West End Street Railway Company of Boston.

Society of Engineers.—The next ordinary meeting of this Society will be held at the Royal United Service Institution, Whitehall, on Monday, October 7th. A Paper will be read on "The Relative Value of Percolation Gauges" by Mr. Reginald E. Middleton.

Bristol-Kingswood Electric Tramway.—The electrical equipment of this line is almost complete, and, as we stated in our last issue, some trial trips have already been run. The electrical equipment of the line consists of 12 motor cars, each provided with two motors, accommodating 18 passengers inside and 25 out.

Compagnie Française des Cables Télégraphiques.—We understand that this Company's Brest-Penzance section has been repaired, and that the "Faraday" has proceeded out to

Digitized by Google

sea for the repair of the Penzance St. Pierre section, which, as announced in *The Electrician* of August 30th, is reported to be broken in 2,500 fathoms.

The Electric Light on the West Coast of Africa.—Amongst various items of purely commercial interest that reached this country from the West Coast of Africa by the last mail we note that at Lagos the natives have taken such determined action by meetings, deputations, &c., against the Government proposal to light the town by electricity—the cost to be defrayed by taxation—that the Acting Governor has informed the Legislature that he would not proceed with the proposal for the present, and has telegraphed to England to stop further expenditure on plant.

Charterhouse Science and Art Schools and Literary Institute.—The winter session of this, one of the largest science and art schools in the United Kingdom, will commence on Saturday, September 28th, under the presidency of the Rev. Henry Swann, M.A. During the late session upwards of 1,200 students, mostly elementary teachers, availed themselves of the privileges afforded by this institution, and of this number 682 presented themselves for examination, and were successful in obtaining a large number of certificates awarded by the Science and Art Department of South Kensington.

The Raworth High-Speed Steam Engine.—We have received particulars of a new high-speed, vertical, enclosed steam engine which has recently been brought out by Mr. Raworth. The cylinders are compounded and steam-jacketed; the effect of the steam is single-acting; there are Corliss valves for admission and exhaust, and the steam valves are controlled by automatic expansion gear. The engine has been very favourably regarded by Prof. W. C. Unwin and Mr. W. H. Maw, the former of whom states that he "should expect it to be an engine which would work with great economy of steam."

Telegraphic Communication between Guernsey and Sark.—For some years past there has been a great desire on the part of the inhabitants of Guernsey and Sark that the latter should be in telegraphic communication with Guernsey. A petition, signed by over 1,000 persons, has been forwarded through the Lieutenant Governor of Guernsey to the Postmaster-General, requesting that a cable be laid down, and in the meantime a military heliographic system has been established and is in great demand. It is worked from the mill at Sark to Fort George, Guernsey, and *vice versa*, and soldiers deliver the despatches.

International Telephonic Communication.—Good progress is being made with the work of establishing telephonic communication between Brussels and Cologne. The line between Brussels and Hertesthal on the Belgian side is finished, while work on the portion on the German side between Hertesthal and Cologne is well in hand. Work is well in hand on the establishment of telephonic communication between Brussels, Antwerp and Amsterdam. When the line is completed the one between Paris and Brussels will probably be connected with it, so that it may be possible ere long to telephone from the Dutch to the French capital.

British Association.—At the last meeting of the General Committee the treasurer (Prof. Rücker) announced that the attendance at the meeting had been as follows:—214 old life members, 13 new life members, 290 old annual members, 31 new annual members, 493 associates, 261 ladies, and 23 foreign members, making a grand total of 1,324. The sum received by subscriptions was £1,236. Certain alterations in the rules as to the making of money grants were proposed by the treasurer and adopted, and the general secretary read a list of money grants appropriated to scientific purposes by the General Committee at the present meeting. The total amount, divided amongst the different sections, was £1,160, and all the grants were confirmed. The Committee then adjourned till Wednesday, September 16, 1896, at Liverpool. The 1897 meeting will take place at Toronto.

Car "Fenders."—After November 14th next, according to an order recently issued by the Railroad Commissioners of Massachusetts, the cars of every street railway in that State must be equipped with "fenders" and wheel guards capable of saving life. Horse cars and trailers are excepted, and a temporary exception is made of cars run wholly within the limits of towns having a population of less than 7,500. No special form of "fender" is indicated, but when the "fender" is designed to serve also as a wheel guard, it must not only pick up a person run into while standing, but prevent a person who has fallen or been thrown down from getting under the car and being run over by the wheels. The Commissioners say: "No one form of fender or wheel guard has as yet been proved to be so unquestionably superior to all others, tried and untried, as to justify the prescription of its sole and its exclusive use"; and the several street railway companies are therefore left free to deal with patentees and inventors for the selection of such "fenders" as will in practice prove most efficient.

Hawaiian Cable Concession.—Reuter's Agency learns that, according to arrangements recently entered into between an American sugar planter and the Hawaiian Government, a contract has been signed granting an annual subsidy of $40,000, with an exclusive right for 20 years to land a cable from the American Continent. By this arrangement, which has been ratified by the Legislature of the Republic, the Hawaiian Government bind themselves not to permit the landing of any other cable on the Hawaiian group. The contractors, however, make it conditional that the line will not be constructed until an annual subsidy of $175,000 has been arranged with the United States Government. According to the contract the line must be commenced in May, 1897, and completed in November, 1898. The negotiations for the contract were conducted with the Hawaiian Republic with the greatest secrecy, and, on it becoming known that it was signed, a meeting of the Honolulu Chamber of Commerce was immediately called, at which the British and German members protested against the granting of any exclusive right.

Expiry of a Swan Glow Lamp Patent.—On the 29th prox. will expire patent No. 4,202 of 1881, granted to Mr. Joseph Wilson Swan for "Improvements in and Relating to Incandescent Electric Lamps." In carrying out the invention the patentee states that he "welds together by means of a deposit of hard carbon, the ends of the filament and the metallic sockets into which the ends are inserted," after shaping the ends of the leading-in wires to suit the shape of the filament. The patentee describes three methods of carrying out his process: (I.) The filament is electrolytically coated with copper everywhere, except on the parts inserted in the sockets and for a short length of about 1mm. beyond. It is then removed from the plating bath, carefully washed and dried, and next immersed in a bath of any suitable hydro-carbon liquid or vapour "from which carbon deposits with the action of heat." A current is then passed through the filament of such a strength that the uncoppered portions "become so strongly heated that a deposit of carbon takes place," the process being continued "until a considerable deposit of carbon resulting in a bulbous enlargement of the parts on which it has taken place is obtained, and the welding together of the sockets and ends of the filament already referred to is effected." (II.) The filament, in this process, is immersed in a bath of mercury, "or other suitable liquid metal," nearly up to the point of attachment to the sockets, and the containing vessel filled above the bath with a suitable hydro-carbon liquid or vapour. On a current of proper strength being passed through the filament in the same manner as before, the exposed portion of the filament becomes coated with a carbonaceous deposit. (III.) The deposit is obtained in the third method by placing a metal clip across the carbon filament, immersed as described in a hydro-carbon liquid or vapour, close to the point of its attachment to the sockets. On connecting the leading-in wires to a source of current, the current is shunted from the main portion of the filament and heats the portion in and near the sockets. The claims of this patent were two in number: (1) Producing by means of electric heating a coating or deposit of carbon over the junction of the metallic socket and the carbon filament inserted in it. (2) In producing a liquid carbon deposit above mentioned, the application of a metallic deposit by electrical action to the part of the filament required to be kept cool, and on which the carbon deposit is not to take place.

ELECTROMAGNETIC THEORY.—LXXIV.*

BY OLIVER HEAVISIDE.

(*Continued from page 573.*)

§ 287. Passing to the consideration of the application of the expansion theorem to diffusion problems, take first what is one of the simplest cases, as well as one of the most interesting. Let a cable be earthed at both ends, and a steady impressed force e be inserted at $x=0$. The potential produced is given by (17), § 256, namely

$$V=\frac{\text{shin}\, q(l-x)}{\text{shin}\, ql}e=\frac{\sin s(l-x)}{\sin sl}e, \qquad (40)$$

where $q^2=-s^2=\text{RS}p$. The practical way of getting this operational solution was described on the same page. Being an easy case, we can see that it is right by noting that it makes $V=0$ at $x=l$, and $V=e$ at $x=0$.

Take the form (30) of the expansion theorem. Take Y to be the numerator, and Z the denominator. The roots of Z are those of shin ql. But not the zero root, because to rationalise shin ql, which is an odd function of ql (and therefore of $p^{\frac{1}{2}}$), we must exclude it. This may be formally done by making Z be (shin ql)/ql; but it is unnecessary, for by omitting the zero root from shin $ql=0$ we come to the same result. Noting this, we may use either of the forms given in (40). The first gives the result in terms of the values of p. But these are negative, therefore the second form is the most convenient. So we have

$$p\frac{dZ}{dp}=\tfrac{1}{2}s\frac{dZ}{ds}=\tfrac{1}{2}sl\cos sl. \qquad (41)$$

Also, putting $p=0$, the final steady state is $e(1-x/l)$. So the expansion theorem (30) gives

$$V=e\left(1-\frac{x}{l}\right)+e\Sigma\frac{\sin s(l-x)\epsilon^{pt}}{\frac{1}{2}sl\cos sl}, \qquad (42)$$

where the summation ranges over the finite roots of $\sin sl=0$; that is, $sl=\pi$, 2π, 3π, &c.; and p in the exponential function is given by $\text{RS}p=-s^2$. Owing to the dependence of p on the square of s, we see that only the positive roots of $\sin sl=0$ need be counted. That is, it is really the values of p that control matters. Equation (42) may be at once reduced to

$$V=e\left(1-\frac{x}{l}\right)-2e\Sigma\frac{\sin sx}{sl}\epsilon^{pt}, \qquad (43)$$

which was obtained before.

§ 288. Next take the same case as last with the sole change made of insulating instead of earthing at $x=l$. Then, by (22), § 258, the potential is given by

$$V=\frac{\cosh q(l-x)}{\cosh ql}e=\frac{\cos s(l-x)}{\cos sl}e, \qquad (44)$$

which, as before, we see to be correct by the formula making $V=e$ at $x=0$, and $C=0$ at $x=l$. Now in this case, the denominator is rational, as a function of p, that is to say, so no reservation is needed, and the expansion theorem (40) makes

$$V=e+e\Sigma\frac{\cos s(l-x)}{\frac{s}{2}\frac{d}{ds}\cos sl}\epsilon^{pt}; \qquad (45)$$

ranging over the positive roots of $\cos sl=0$; or, $sl=\frac{1}{2}\pi$, $1\frac{1}{2}\pi$, &c. Effecting the differentiation in the denominator, and simplifying the numerator by the vanishing of $\cos sl$, we reduce (45) to

$$V=e-2e\Sigma\frac{\sin sx}{sl}\epsilon^{pt}, \qquad (46)$$

which is the expansion required. The summational part is of the same form as in (43). But of course there is a different series of values of sl, and also of the p's. There is no confusion between p the differentiator, and its specialised algebraical values denoted by the same symbol. The latter only occur in algebraical summations; the former in operational solutions.

§ 289. The above two cases being sufficiently illustrative when the impressed force is situated terminally, and the terminal conditions are of the simplest type, making either the potential or the current vanish, take next the case of an intermediate impressed force, though still with the simple terminal conditions. Say that there is earth on at $x=0$, insulation at $x=l$, and an impressed force e at $x=y$. Then, by (41), (42), § 260, the resulting potentials, putting $q^2=-s^2$ for convenience in the expansions to be found, are given by

$$V_1=\frac{\cos sy}{\cos sl}\cos s(l-x)\,.\,e, \qquad (47)$$

$$V_2=\frac{\sin sx}{\cos sl}\sin s(l-y)\,.\,e, \qquad (48)$$

V_1 being the potential when x is on the right side of y, and V_2 when on the left side. Here, of course, s^2 is the differentiator $-\text{RS}p$.

First, putting $s=0$, we see that the final steady state is $V_1=e$, $V_2=0$. So applying (30), we obtain

$$V_1=e-e\Sigma\frac{\cos sy}{\frac{1}{2}sl\sin sl}\cos s(l-x)\,.\,\epsilon^{pt}, \qquad (49)$$

$$V_2=0-e\Sigma\frac{\sin sx}{\frac{1}{2}sl\sin sl}\sin s(l-y)\,.\,\epsilon^{pt}, \qquad (50)$$

subject to $\cos sl=0$, as in the last case, or $sl=(n-\frac{1}{2})\pi$, where n is a positive integer. We may now simplify by means of $\cos sl=0$, leaving

$$V_1=e-2e\Sigma\frac{\cos sy}{sl}\sin sx\,.\,\epsilon^{pt}, \qquad (51)$$

$$V_2=\ -2e\Sigma\frac{\cos sy}{sl}\sin sx.\,\epsilon^{pt}, \qquad (52)$$

the simplest form of the expansions.

The transition from the operational solutions (47), (48) to the expansions (49), (50) involves two formal processes, viz., the change in the denominator, done by the differentiation which occurs when the summational sign and the time factor are introduced, and the addition of the outside term. In going further, we reach (51), (52), by the omission of terms which vanish in the preceding equations. The same occurs in the previous examples. Now this omission may be done in the act of applying the expansion theorem, thereby deriving (51), (52) directly from (47), (48) without the more complicated intermediate equations. And, in fact, so far as arriving at (51), (52) is concerned, through the expansion theorem, we may make the omission in the operational solution. But the steady part of the solution must be extracted first; and in any case, the operational solution is made nonsense of (considered as a general operational solution) by the too early omission. So the omission is properly done in the act of conversion to the expanded series.

§ 290. If both terminals are earthed, whilst the impressed force is intermediate, at the point y, we have, by (37), (38), § 260, the results

$$V_1=+\frac{\cos sy}{\sin sl}\sin s(l-x)\,.\,e, \qquad (53)$$

$$V_2=-\frac{\sin sx}{\sin sl}\cos s(l-y)\,.\,e, \qquad (54)$$

on the right and left sides of the impressed force respectively. So the expansion theorem makes

$$V_1=e\left(1-\frac{x}{l}\right)-2e\Sigma\frac{\cos sy\sin sx}{sl}\epsilon^{pt}, \qquad (55)$$

$$V_2=-\frac{ex}{l}-2e\Sigma\frac{\cos sy\sin sx}{sl}\epsilon^{pt}, \qquad (56)$$

where we first write down the outside terms got by putting $s=0$ in the previous equations, and then write the summational general term, changing the denominator by the operator $\frac{1}{2}s(d/ds)$, which is equivalent to $p(d/dp)$, and omitting terms

* This series of articles is a portion of Vol. II. of Mr. Heaviside's work "Electromagnetic Theory." All rights of reproduction are reserved.

Digitized by Google

which, in virtue of $\sin sl = 0$, vanish from the result with changed denominator.

The determinantal equation depends only upon the nature of the terminal conditions apart from impressed force. There may be any distribution of impressed force, intermediate or at the terminals as well, but unless we change the terminal arrangements, there will always be the same set of normal systems. In (55), (56), for example, e is entirely at the point y. But make it be a function of y, representing a distributed impressed force. Then the integration of (55), (56) with respect to y, so as to include all the impressed forces, will give the resulting potential. The outside terms are altered, and likewise the size of the normal systems in the summation, but the type of the normal systems, say $\sin sx\, \epsilon^{pt}$, is not changed, and the same series of s's and p's remains in force.

§ 291. Owing to the equidistant spacing of the roots of the determinantal equation in the above cases, which arises from the fact that the terminal reflection coefficients are of size $+1$ or -1, as the case may be, the expanded solutions are readily calculable numerically at once. It is somewhat different when we depart from the simplicity of terminal earth or insulation, as the roots become unequally spaced, and require preliminary determination from trigonometrical tables before the formulæ can be subjected to calculation. The process of expansion is, however, the same. Let, for a first case, the impressed force be at the beginning, $x = 0$. Then we only want the formula on the right side of the force. This is (35), § 259, in which put $a = 0$, making

$$V = \frac{1 - \alpha}{\epsilon^{ql} - \alpha\beta\epsilon^{-ql}}\{\epsilon^{q(l-x)} + \beta\epsilon^{-q(l-x)}\}\tfrac{1}{2}e, \qquad (57)$$

which shows the potential at x due to e at $x = 0$, when the terminal reflection coefficients are α and β, at $x = 0$ and l respectively. In terms of the terminal resistance operators Z_0 and Z_1, we have

$$\alpha = \frac{Z_0 - R/q}{Z_0 + R/q}, \qquad \beta = \frac{Z_1 - R/q}{Z_1 + R/q}, \qquad (58)$$

by § 261, equations (49) and (52). Here Z_1 is such that $V = Z_1C$ is the equation of voltage for the terminal arrangement at $x = l$, and $V = -Z_0C$ for that at $x = 0$.

When the terminal arrangement is a mere resistance, we have $Z_0 = R_0$ say, and $Z_1 = R_1$, these being constants. Notice, in passing, the singular case $\alpha = 1$. By (57) it makes $V = 0$; that is, the cable cannot be charged at all. This happens when Z_0 is infinite, which needs an infinite terminal resistance at every moment, and no permittance.

Going further, let us expand (57). The best way is, by means of the given expressions for α and β, to convert it to circular form first, before applying the expansion theorem, although it will come to the same thing in the end if we expand (57) as it stands, and then change to circular functions. Adopting the former course, put $q = si$ in (57) and (58), and reduce by ordinary algebra. The result is

$$V = \frac{\{\sin + (Z_1 s/R)\cos\} s(l - x)}{(1 - Z_0 Z_1 s^2/R^2)\sin sl + (Z_0 + Z_1)(s/R)\cos sl}\,e. \qquad (59)$$

This is, by its construction, only another form of the operational solution itself, the meaning of s^2 being $-RSp$. Observe, also, that although Z_0 and Z_1 are unspecified, no further reductions of the kind just made are required for them in any case allowing of the application of the expansion theorem, because they are then rational functions of p, and therefore of s^2. So (59) is the operational solution in a form which is convenient for the immediate application of the expansion theorem.

Put $s = 0$ to find the steady state. Practically, put 1 for $\cos sl$ and $\cos sx$, and sl or sx for $\sin sl$ and $\sin sx$. The result is

$$V_0 = \frac{R(l - x) + Z_1}{Rl(1 - Z_0 Z_1 s^2/R^2) + Z_0 + Z_1}\,e. \qquad (60)$$

Now if the terminal arrangements are mere resistances, say R_0 and R_1, this becomes

$$V_0 = \frac{R(l - x) + R_1}{Rl + R_0 + R_1}\,e, \qquad (61)$$

which is obviously right, because the denominator is the total resistance of the circuit, and the numerator is that part of it which lies to the right of the point x. Similarly, if the terminal arrangements, though not simple resistances themselves, have finite steady resistances, then $s = 0$ in Z_0 and Z_1 produces them, and (61) is still the result, where R_0 and R_1 denote the effective steady resistances. But it may happen that the term containing s^2 in (60) does not vanish. It may be infinite, so caution is needed when the effective terminal resistance is infinite. Thus, (60) may be written

$$V_0 = \frac{R(l - x) + Z_1}{Rl(1 + Z_0 Z_1 Sp/R) + Z_0 + Z_1}\,e, \qquad (62)$$

in terms of p. Now suppose the terminal arrangement at A is a condenser, making $Z_0 = (S_0 p)^{-1}$. The p is cancelled. But at the same time the denominator is made infinite, R_0 being infinite. So if R_1 is finite, the result is $V_0 = 0$. That is, the cable settles down to a neutral state ultimately when charged through a condenser, provided there is not infinite resistance at the further end. On the other hand, when the condenser is at B, making $Z = (S_1 p)^{-1}$, say, the result is $V = e$, the full value, provided the resistance at A is finite. Lastly, if both R_1 and R_0 are infinite, by having condensers at both ends, say $Z_1 = (S_1 p)^{-1}$, $Z_0 = (S_0 p)^{-1}$, the result of putting $p = 0$ in (62) is

$$V_0 = \frac{S_0 e}{S_0 + S_1 + Sl}. \qquad (63)$$

This result may be verified by the law of displacement in condensers. On one side of the impressed force is the elastance S_0^{-1}, and on the other side $(S_1 + Sl)^{-1}$. So the total displacement is

$$\frac{e}{S_0^{-1} + (Sl + S_1)^{-1}} = \frac{eS_0(Sl + S_1)}{S_0 + Sl + S_1}, \qquad (64)$$

Divide by $Sl + S_1$ the permittance on the right side of e, and the result is V_0, as in (63), the final steady potential of the cable and further condenser. On the other side of the impressed force—that is, on the side of the condenser at A which is next the cable—the potential is negative, being lower than the above V_0 by the amount e. It is the side of the condenser at A next the earth that is charged positively. The reverse is the case in the dielectric of the cable and the B condenser. The simplest mental realisation is obtained by the use of Maxwell's displacement current.

If we compare these cases with the formula (61), understanding that R_0 and R_1 are the steady terminal resistances, we see that they are in agreement, except that when R_0 and R_1 are *both* infinite, the result (61) is ambiguous. In such a case we must go back to the more complete formula (60), or (62), and interpret it instead.

Having thus settled V_0, the outside term to express the steady state when there is one, we may apply the expansion theorem to (59) or to any form of the same that may be more convenient. Another form is

$$V = \frac{\cos sx(\tan sl + Z_1 s/R) + \sin sx(\tan sl \,.\, Z_1 s/R - 1)}{(1 - Z_0 Z_1 s^2/R^2)\left(\tan sl + \dfrac{(Z_0 + Z_1)s/R}{1 - Z_0 Z_1 s^2/R^2}\right)}\,e, \qquad (65)$$

obtained from (59) by expanding the numerator, and then dividing the numerator and denominator in that equation by $\cos sl$.

The determinantal equation is

$$\tan sl + \frac{(Z_0 + Z_1)s/R}{1 - Z_0 Z_1 s^2/R^2} = 0, \qquad (66)$$

or, which is the same,

$$\tan sl = -\frac{Rl(Z_0 + Z_1)sl}{(Rl)^2 - Z_0 Z_1 (sl)^2}. \qquad (67)$$

This simplifies to

$$\tan sl = -\frac{Z_0}{Rl}sl, \qquad (68)$$

when $Z_1 = 0$, and to

$$\tan sl = -\frac{Z_1}{Rl}sl, \qquad (69)$$

when $Z_0 = 0$. In these equations the Z's are functions of $(sl)^2$ in virtue of being functions of p in general.

In the case of the terminal arrangements being mere resistances, producing a constant ratio of the potential and current at the terminals, we have the simple terminal conditions considered by Fourier. Z_0 or Z_1, or both, as the case may be, are constants. The values of sl are then very easily determined by means of a table of tangents. This kind of terminal condition, which includes the extreme cases of terminal earth and insulation, is the only one that admits of the expansion of an arbitrary function after the manner of Fourier—that is to say, by the use of the property of the vanishing of the integral of the product of any two different normal systems. The reason is because there is no energy in the terminal arrangements that can by itself affect the state of the cable. It is true that there is waste of energy in the terminal resistances, but that does not count at all. It is wasted and done for. So the specification of the initial state merely requires a statement of the potential in the cable itself; that implies electric energy, upon which the later state of the cable when left to itself depends, in the absence of an impressed force to introduce fresh energy. But whenever the terminal arrangement departs from the above simple type, involving merely a waste of energy from the cable, Fourier's method fails. The integral of the product of two normal systems along the cable is no longer zero. The initial state may or may not include any energy in the terminal arrangements. If it does, this terminal energy must be allowed for by widening the conjugate property, or in other ways. But even if it does not, the energy in the cable itself will set up energy in the terminal arrangements in a reversible manner, not by mere waste, so the complete normal systems must include the terminal arrangements as well as the cable. Now if the terminal arrangements consist only of condensers and resistances (or equivalently), however complicated in detail, we only introduce electric energy. This is like that in the cable (its self-induction being ignored here), viz., the energy of electric displacement. The conjugate property which has to take the place of Fourier's is then substantially the same, with a wider range, however. It is the property of the vanishing of the total mutual energy of a pair of complete normal systems. But should we introduce magnetic energy into either or both of the terminal arrangements, the last property breaks down. We have to go to a still wider one, viz., that the mutual potential energy (or electric, here), of a pair of normal systems equals the mutual magnetic energy of the same, the terminal arrangements being included. This may work out in a complicated manner.

But the expansion theorem goes straight to the final simplified result, irrespective of the absence or presence of energy or of the power of receiving and storing energy in the terminal arrangements, and of the kind of conjugate property required to effect the expansion after the manner of Fourier extended. Thus, applying it to (65), following the formula (30), and using $\frac{1}{2}s\,(d/ds)$ instead of $p(d/dp)$, we obtain

$$V = V_0 + 2e\Sigma \frac{\cos sx\,(\tan sl + Z_1 s/R) + \sin sx\,(\tan sl\,.\,Z_1 s/R - 1)}{sl\,(1 - Z_0 Z_1 s^2/R^2)\left(\dfrac{1}{\cos^2 sl} + \dfrac{d}{d(sl)}\,\dfrac{(Z_0 + Z_1)s/R}{1 - Z_0 Z_1 s^2/R^2}\right)}\epsilon^{pt}, \tag{70}$$

by performing one differentiation upon the denominator in (65). We cannot carry it further profitably without specifying what the natures of Z_0 and Z_1 really are. Since, however, the values of sl in the summation are fixed by the equation (66), that is by the vanishing of the denominator in (65), we may substitute the right member of (67) for tan sl in (70), and similarly put $\sec^2 sl$ in terms of the Z's. But there is no particular advantage in doing so, unless the Z's are given, and we desire to make possible simplifications of expression.

In obtaining (70) by the expansion theorem, no notice was taken of the factor $(1 - Z_0 Z_1 s^2/R^2)$ in the denominator in (65). It has its roots truly, but they are inoperative. They lead to nothing. The factor may therefore be regarded as belonging to the numerator of (65), if we please. Or, keeping it in the denominator, we see that its vanishing does not make the denominator vanish, and therefore its roots are out of the question.

(To be continued.)

MOLECULAR ELECTRICITY.

BY J. H. POYNTING, SC.D., F.R.S.

(Continued from page 647.)

When a line or tube of induction moves sideways into an electrolyte composed of such condenser molecules it finds the molecules with their axes distributed equally in all directions. It will pick out those already facing in the direction suitable for it—those requiring the least energy for its purpose, and those alone need be drawn.

In Fig. 4 (*a*) two lines of induction, X X, Y Y, are represented as ready to move into an electrolyte, in which A B, A B represent the suitable molecules.

The successive stages are represented by *b*, *c*, *d*, *e*, and the final result is that the highest B atom is delivered up to the

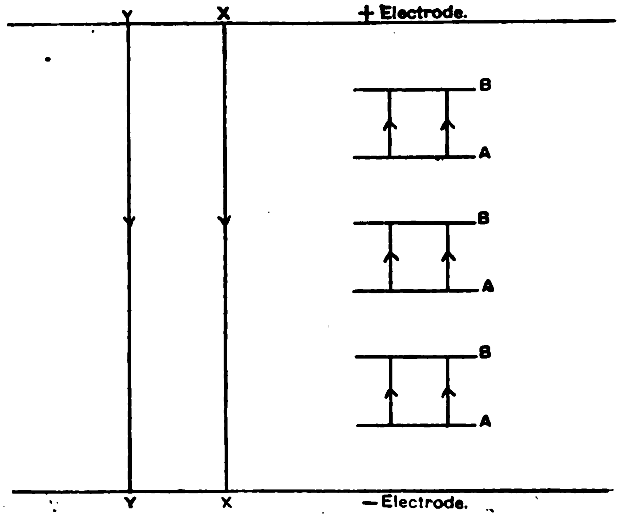

FIG. 4*a*.

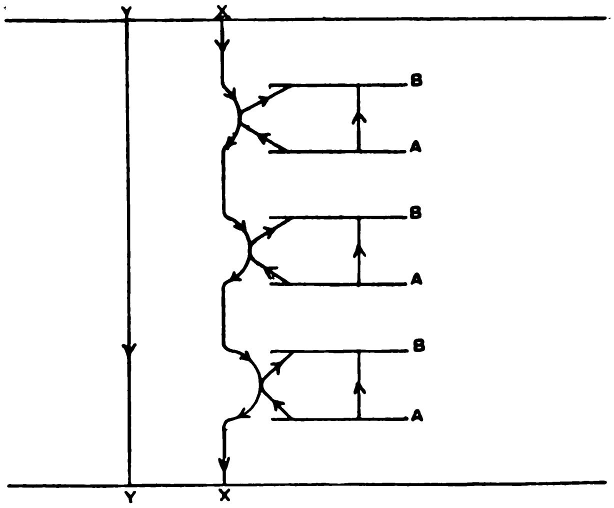

FIG. 4*b*.

+ electrode, and the lowest A atom to the − electrode, while all the intermediate atoms in the chain change partners, merely forming molecules like the original ones, but with their axes reversed.

If more lines come in they will find new molecules directed as they require, and soon also the collisions occurring in the liquid will distribute the axes of the molecules of the first chain into various directions, so that some of these, too, will be ready for later lines of induction.

The coalescence and destruction of the parts of two tubes which run alongside each other in opposite directions, upon which the whole process depends, will naturally tend to take place, as less potential energy will be needed for the coalesced tubes than for the two side by side. The energy of the final configuration is the same as that of the initial configuration,

Digitized by Google

except at the two ends, so that if X X and Y Y bring in enough energy to provide for the new configurations at the electrodes the process will continue. If X X and Y Y bring in an excess of energy we may regard the change of partners as occurring with more or less of a rush, and the excess is converted into internal molecular energy, partly kinetic, partly potential; in

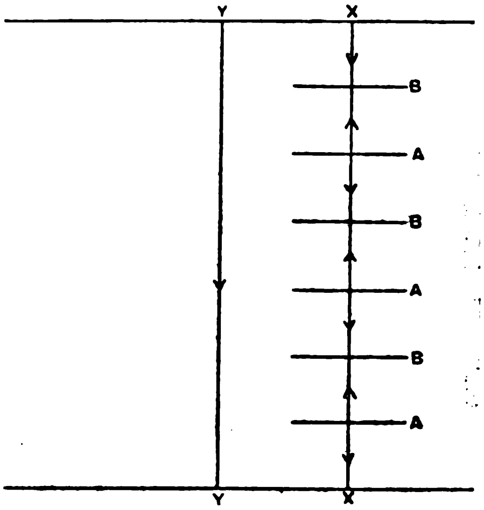

Fig. 4*c*.

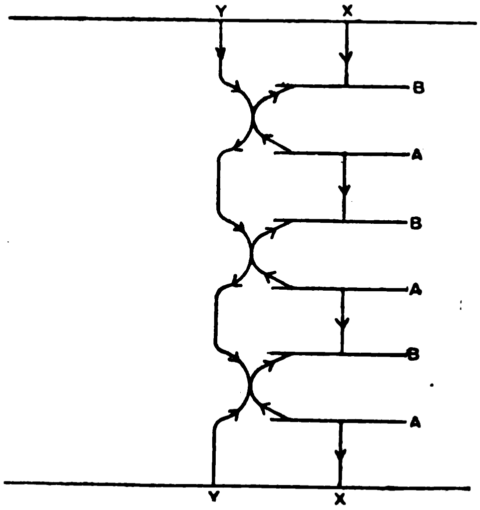

Fig. 4*d*.

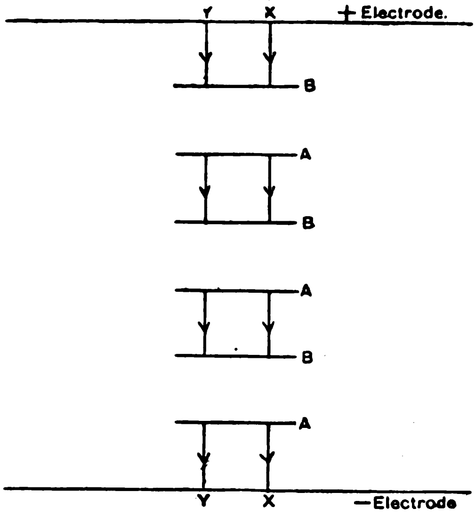

Fig. 4*e*.

fact, the chain of recombined molecules is warmer than it was, and we have the Joule C^2R effect.

For simplicity we have considered the tubes X X, Y Y as stretched through free space till they come to the chain of molecules which they are to rearrange. But it is easy to see how a tube may be handed on from chain to chain without any free existence. In Fig. 5 (*a*) a tube X X already threads a chain of A B molecules and in *b*, *c*, *d*, are shown the successive stages of its transfer to a neighbouring chain. The process is rendered more capable of representation by supposing each member of the second set of molecules lifted its own depth upwards. The derivation of each stage from the preceding is evident. This is doubtless the process which we must suppose to occur in all cases, and the tubes must be regarded as threading such chains in the dielectric, even before they enter the electrolytic cell.

Let us now consider what must happen at the electrodes. If the ions unite chemically with the electrodes, the positive and negative atoms find respectively negative and positive atoms ready to combine with them, and no difficulty is introduced at this point. But if the ions are set free, as are hydrogen and oxygen at platinum electrodes in dilute acid, we are brought face to face with the great, and, it is to be confessed,

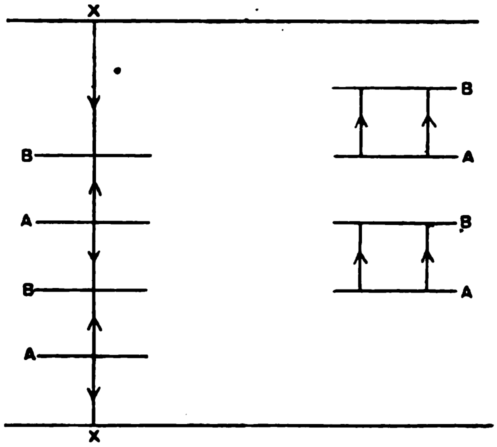

Fig. 5*a*.

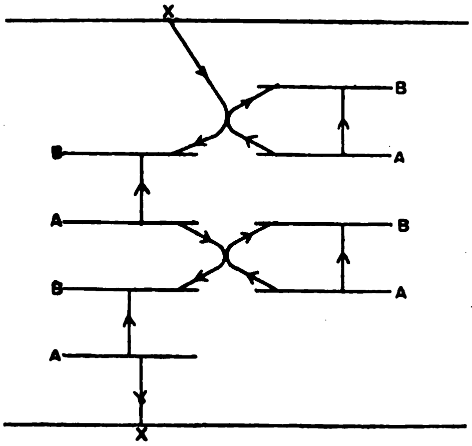

Fig. 5*b*.

the yet unsolved difficulty in the hypothesis. Take the case of the hydrogen atoms released at the cathode, the atoms such as the lowest A in Fig. 4 (*e*). We may think of them as connected at first by tubes of induction going from them to platinum atoms on the surface of the cathode. But soon the gas bubbles up, and there is no manifestation of the charge all of one kind which we have ascribed to the separate hydrogen atoms. We may attempt several explanations. The common notion appears to be that the hydrogen gives up its charge to the platinum, and then rises up quite deprived of electricity. This might occur by the breaking away of the tubes from the hydrogen atoms and the withdrawal of the positive ends into the platinum, the positive charge moving across the separating space, like a disembodied soul, from its hydrogen habitation into the platinum. The platinum having two neutralising souls, becomes as merely material as the deserted hydrogen. But this is strongly against

Digitized by Google

our experimental knowledge of charge, which is always, so far as we know, on matter, whereas here charge crosses over a separating space. We might suppose this got over by thinking of the hydrogen and platinum atoms as coming absolutely in contact, shortening the connecting tubes to nothing, and putting them out of existence. If the tubes are not re-created when the hydrogen rebounds the gas rises up without electricity.

But, according to the current ideas of chemistry, the hydrogen issuing from the cell is not atomic, but molecular, and consists of paired atoms at least; that is to say, it is a chemical compound, differing from ordinary compounds it is true, in that the two members of each molecule are the same in kind, but the atoms are held together by chemical attraction, and satisfy each other's chemical affinity just as much as if they were different elements. If our hypothesis has any truth in it, this means that electric induction exists between the atoms and holds them together, a view supported, I think, by the phenomena of electric discharge

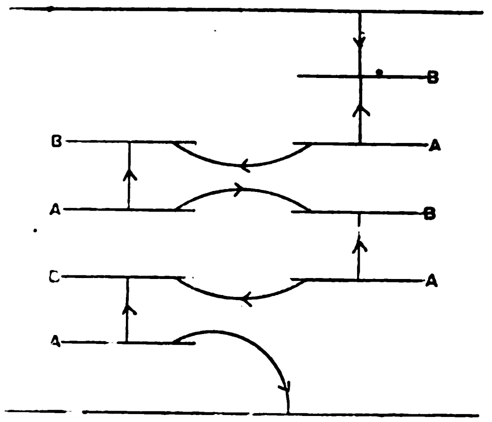

Fig. 5*c*.

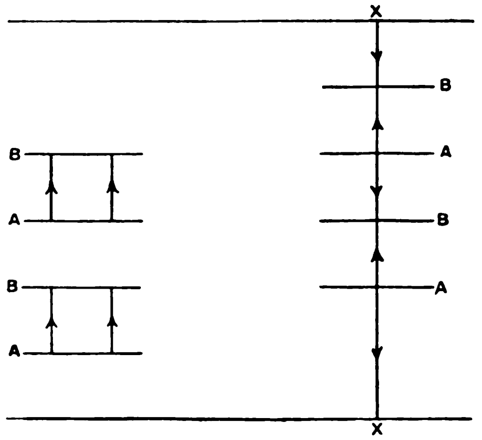

Fig. 5*d*.

in gases and the electrolysis which appears to take place in that discharge. To be consistent, then, we must suppose that the hydrogen, when it rises up, consists of pairs of + and − atoms, and for us the difficulty is to explain, not what has become of the hydrogen charge, but how half the atoms have succeeded in exactly reversing their charges, so that they are able to combine with the other half to form neutralising pairs. And, of course, we must extend our supposition of the constitution of an element as being made up of + and − atoms to the platinum also. When the lines of induction move into the platinum, the − atoms of the surface pairs are freed from their + partners, and are free to form pairs with the + hydrogen atoms. But when half the hydrogen reverses its charge half the platinum must do the same in order that it too may effect the neutral combination which we find when the electrolysis has ceased. Perhaps the best course is to say that if our main hypothesis of identity of chemical attraction and electric induction is real, then the reversal of charge, such as occurs on our supposition at the electrodes, is up to the present an unexplained, an ultimate fact. Without attempting explanation, but rather as a crude mode of picturing a process which would lead to the result, we might think of a + H and a − Pt as coming absolutely in contact, so that the tube ends can slide round on the surface of the atoms and across the bridge of contact until + is on the Pt and − on the H. Possibly Fig. 6 will make this clearer.

In (*b*) two atoms have come in contact, in (*c*) the tubes are beginning to slide round, in (*d*) the ends have changed places, and in (*e*) the atoms have drawn apart with reversed charges.

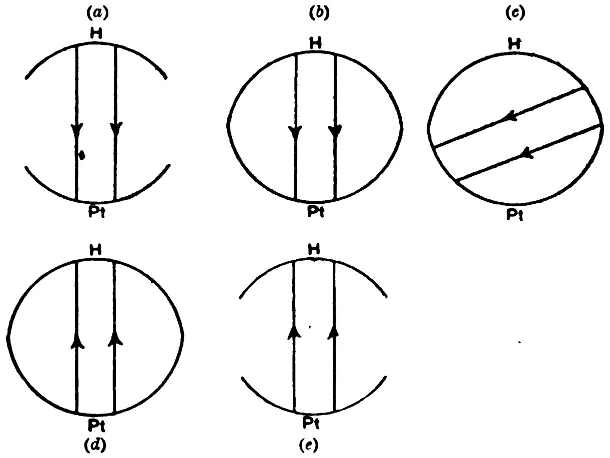

Fig. 6.

Having thus or otherwise reversed half the pairs, combination with the other half may ensue as in Fig. 7, the result being hydrogen molecules and platinum molecules each consisting of + and − pairs.

At first sight it seems as though the reversal occurring in the spark discharge of a Leyden jar or a Hertz vibrator would give us the key to the reversal pictured in Fig. 6. But further examination takes away this hope. The jar reversal is never complete and exact such as we have to suppose the atomic reversal. Indeed, the induction may have any value, + or −, less numerically than the initial value, as it gradually dies

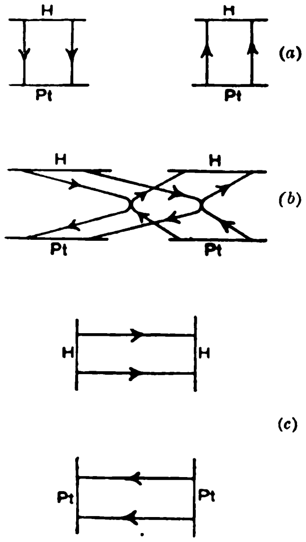

Fig. 7.

down to zero through the successive vibrations. We shall see later how some account may be given of the reversal in vibrators, an account which quite destroys any analogy with atomic reversal.

Perhaps a better analogy is afforded by two vortex rings A and B when they are playing at leap frog. The first widens out and lets the second go through it. Before the passage the liquid is streaming through A towards B. After the passage it is streaming from B towards A, so that if we think of induction as corresponding to direction of flow we have here a

Digitized by Google

reversal. But I suspect that this liquid analogy is much more appropriate to a magnetic than to an electric hypothesis.

Were it not for the magnetic difficulties involved there would be some temptation to attempt a theory in which the sign of charge is merely a statement of the kind of atom concerned, and that the tubes, like gravitation tubes, have nothing but alignment and neither + nor − direction. But this would, I fear, be getting over one difficulty only by introducing much greater difficulties hereafter.

We shall assume, then, that in some way or other reversal can take place in certain cases, and we may apply it at once to explain the apparently neutral condition of the ions in the electrolytic cell. We suppose that half the ionic atoms in Fig. 4 reverse or change charges with the electrode atoms, as in Fig. 6, and that then they go through the process of Fig. 7 with the other half, and so form + and − pairs, exhibiting no external electrification.

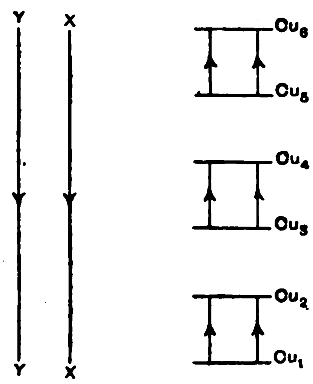

Fig. 8*a*.

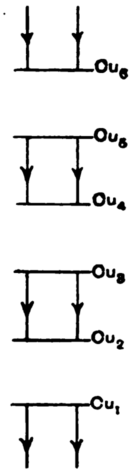

Fig. 8*b*.

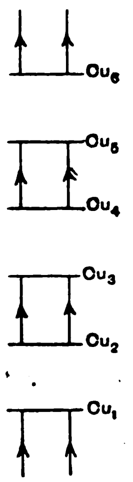

Fig. 8*c*.

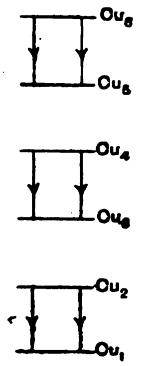

Fig. 8*d*.

A similar reversal will enable us to give an electrolytic account of metallic conduction. The great distinction between electrolytes and metals is that in the former there are opposite atomic processions, while in the latter there is apparently no motion in either direction. Electrolysis without procession means, as we have just seen with the electrodes, where the procession stops, reversal of charge. Suppose, then, that such reversal is possible with every metallic molecule. Imagine a copper wire carrying a current to be made up of molecules, as represented in Fig. 8 (*a*), and let tubes of induction X X, Y Y be just moving into the wire. Before the current is established the molecular axes are evenly distributed in all directions, but the tubes entering in select those most suitable, as shown in (*a*), turning the configuration to that shown in (*b*); if now reversal takes place we get (*c*). Let two more tubes come in, and we get (*d*), a reversal of which gives the same arrangement as (*a*) as far as the copper is concerned, but the four entering tubes of induction have entirely disappeared.

(*To be continued*)

AN IMPROVED PORTABLE PHOTOMETER.*

BY W. H. PREECE, C.B., F.R.S., AND A. P. TROTTER, B.A., A.M.I.C.E.

When light falls upon a surface, that surface is said to be illuminated. The illumination depends simply upon the light falling upon the surface, and has nothing to do with the reflecting power of the surface, just as rainfall is independent of the nature of the soil. As a rain gauge receives the full amount of rain when it is placed horizontally (disregarding wind), and receives less when it is tilted, so the surface is fully illuminated when it faces the source of light, and is less fully illuminated when the light falls upon it at an angle. The proportion between the full rainfall or illumination and the measured rainfall or illumination varies as the cosine of the angle of incidence of the rain or of the light. This angle is 0deg., and the cosine is 1, when the rain gauge is placed horizontally, or when the light falls perpendicularly on the surface. It would, perhaps, be unnecessary to call attention to these very elementary matters were it not that the difference between the photometry of illumination and the ordinary photometry of candle-power is often confused.

The lighting of streets and of buildings may be specified by the maximum and minimum illumination. The primary purpose of an illumination photometer is to measure the resulting illumination produced by any arrangement of lamps, irrespective of their number, their height, or of their candle-power. Illumination photometers containing sub-standards of light have been designed by Prof. Weber,† Prof. Mascart‡ and others. One of us described an illumination photometer before the Royal Society in 1883.§ This consisted of a box blackened within. Over the end was stretched a Bunsen screen of paper, on the middle of which was a grease spot. At a distance of 12in. was another screen of drawing paper. The grease spot was so screened that no light fell upon it except that which was reflected from the drawing-paper screen. At the end of the box opposite the Bunsen screen was an eyepiece consisting of a plain tube. Within the box a small glow lamp was fixed, and in order to make a measurement of the illumination of the drawing-paper screen, the current through the lamp was varied by a rheostat until the grease spot was invisible. The readings were recorded in *luces*, a *lux* being suggested by one of us at the Paris Electrical Congress, 1889,‖ as the name for the illumination due to a carcel lamp at one metre, and equivalent to a British standard candle at 1·058ft. The only defect of this photometer was the yellowish and reddish colour of the lamp when dimmed for low readings. In 1884 we designed a portable photometer¶ in which the lamp could be moved towards or withdrawn from the Bunsen screen, and a mechanism was provided by which, when a pointer moved a certain distance over a uniformly divided scale, the displacement of the lamp was as the square of that distance. The Bunsen spot was viewed by Rudorff mirrors in the usual way. This instrument worked well, but the range was small, and could not be easily increased. The lamp would have to be moved to a very considerable distance from the screen for measuring the feeble illuminations met with in street lighting. Eight years later one of us experimented with modifications of this instrument, and found that in ordinary street lighting the illumination is often only equal to that due to one candle at 14ft. distance. A large number of different methods of reducing the light were tried. Many combinations of lenses, the eclipsing device used in dissolving views, photographically shaded glass screens, and other devices were used, and finally a white reflecting screen was inclined at different angles to a small electric lamp, and on this principle a photometer was constructed in February, 1892. It was found that the Bunsen screen could be replaced with advantage by a simple white cardboard diaphragm pierced

with one or more holes.* The illumination of this diaphragm, generally in a horizontal position, was the illumination to be measured. Below this was the reflecting screen, enclosed in a box about 2ft. by 6in. by 5in. with a pair of small glow lamps and a secondary battery. The screen could be inclined towards the glow lamps by means of a chain wound up on a cam mounted on a spindle, the cam being formed so as to give an open scale. A hand or pointer on the spindle indicated readings on a dial. Many measurements and a number of photometrical surveys of different streets and public buildings in London were made in 1892, and were recorded by means of plans with isophotal contour lines and otherwise.†

During the present year an improved form of this photometer has been constructed. The chain and cam, which allowed the instrument to be used only in a horizontal position, have been

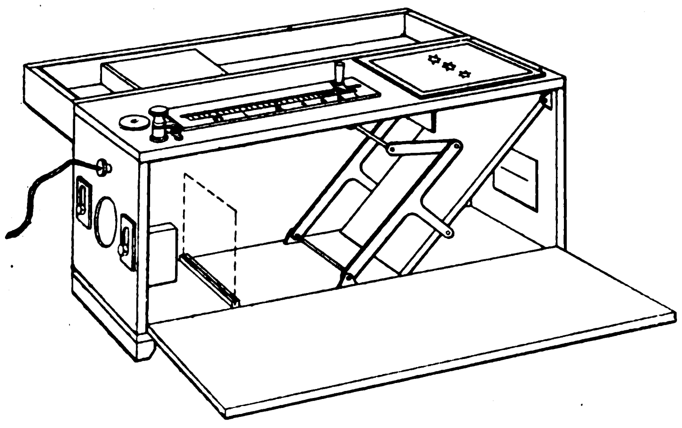

FIG. 1.

replaced by a system of levers. The object of these levers is to give an open scale. If the motion of the pointer were proportional to the angular movement of the screen, the scale would be approximately a scale of cosines. The instrument is shown in Fig. 1 with the lid open and the front let down. It measures 1ft. $3\frac{3}{4}$in. by $5\frac{1}{2}$in. by $9\frac{1}{2}$in. high (400mm. by 140mm. by 242mm.). On the end to the left there is a red glass window, and immediately within are two 12-volt lamps (one of which is shown in Fig. 2), one of about 1 c.p., and the other of 2 c.p. It can be seen through the window if either or both of the lamps are alight. The lamps are held in special lampholders, capable of adjustment as to height by clamping screws. These clamping screws and the base of one of the lampholders are shown in Fig. 1. A switch on the top of the

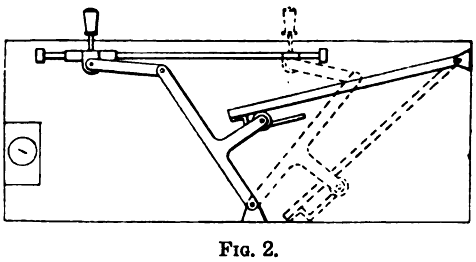

FIG. 2.

instrument enables either or both lamps to be turned on and off. At the other end of the box the reflecting screen is hung. The middle of the screen is about 11in. (28cm.) from the lamps. It is shown in Fig. 1 in the lowest position. In Fig. 2 the screen and one of the levers, together with one of the rollers on which the screen rests, and the handle by which it is moved, are shown with the screen in its highest position by full lines, and in its lowest position by dotted lines. In its highest position the filaments of the lamps are a little below the plane of the screen, no direct light from the lamps then reaches the screen, and it is only faintly illuminated to about $\frac{1}{200}$th of one candle at a foot, by stray light, which is excluded as much as possible. The diaphragm is placed horizontally immediately above the hinged screen. Three small star-shaped holes are cut in it, and through them the illuminated reflecting screen can be seen. A handle carrying a pointer moving over a graduated scale controls the inclination of the screen by means of the levers and links. A guide, attached to the back of the screen (shown in Fig. 2), allows the instrument to be turned on its side without interfering with the working. In order to take a measurement, one or both of the lamps are turned on, and the handle is moved until the screen seen through the holes in the diaphragm matches the diaphragm in brightness. If the colour of the light outside is about the same as that of the lamps, the middle hole may be made to disappear. The observer should stand approximately in the vertical plane passing through the three holes, so that he may see that part of the screen through them which lies immediately beneath them.

Various substances have been tried for the diaphragm and screen. Thin metal painted with a whitewash made of magnesia and isinglass is perhaps the best; the diffused reflection practically follows Lambert's cosine law, but the material is easily soiled and cannot be cleaned. Bristol board from which the glaze has been removed by a damp cloth closely follows the cosine law within the angular range required in this case. It is important that there should be no glaze on the surface of the hinged screen, since the inclination of the lamp to the screen and of the screen to the eye for maximum illumination is about 45deg. But as the scale is graduated by experiment, a slight departure from the cosine law does not matter. On the other hand, it is of greater importance that the screen should be very smooth and flat. Under very feeble illuminations, the light from the small lamp making an angle of incidence very nearly 90deg., minute irregularities are easily seen, and make accurate readings difficult. For ordinary street lighting and for general industrial photometry a slight departure from the cosine law on the part of the diaphragm is of no practical consequence, so long as there is no perceptible glaze, for it is always observed nearly vertically and never at a large angle of incidence.

The colour difficulty is reduced, in the first instance, by the freedom of motion of the levers. The handle may be quickly moved to and fro on each side of the true reading, and the middle position may be estimated. In measuring the illumination due to arc lamps, the colour difficulty becomes troublesome. The colour of the glow lamp in the photometer should be approximately a mean between the colour of the standard of light wherewith the instrument is calibrated, and that of an arc lamp. This halves the difficulty, which can never be entirely removed, since differently-coloured lights are not physically comparable; it may, however, be relegated entirely to the laboratory by the use of a coloured screen and diaphragm.

If the hinged screen be tinted pale blue, some of the yellow rays of the lamp in the photometer are absorbed, and the reflected rays approximate to grey—that is, to feebly illuminated white. On the other hand, if the diaphragm is tinted yellow, the white light from electric arcs, or of daylight, may be reduced to approximately the same colour as that of the lamp in the photometer. In the first case the brilliance of the hinged screen is reduced, and a brighter lamp would have to be used to restore the true value of the scale readings; and in the second case the brilliance of the diaphragm would be reduced, and the scale readings would be too high. But by tinting both screens the calibration of the instrument need not be disturbed.

The screen being coloured pale blue and the diaphragm pale yellow, there is no difficulty in obtaining disappearance of the hole in the diaphragm when illuminated by arc light or even by daylight. The selection of the colours suitable for obtaining a true measurement is based upon the mean of a number of measurements. White screens are used, and the comparison should be made in a building illuminated by a number of arc lamps. A number of measurements are made with quick oscillations of the handle, and the mean is taken. Several screens and diaphragms of different tints being in readiness, pairs are tried and a selection is made of a pair which give a good

† *Proc.* Inst. C. E., Vol. CX., pp. 42-51.

Digitized by Google

colour match,* and, if possible, the mean reading given by the white screens. A slight departure from the mean could be corrected by the use of a coefficient. It is not suggested that strongly coloured lights can be scientifically compared in this manner, but only that the yellowish light of a glow lamp may be compared with the whitish light of an arc or of subdued daylight. We employed this device in 1884, and Messrs. G. W. and M. R. Patterson, the translators of Palaz's "Industrial Photometry," who have used it in connection with a Lummer-Brodhun photometer, remark† that it "can, of course, give no additional absolute accuracy to the photometric measurements; it, however, adds greatly to the comparative accuracy of the results, as it makes it possible to measure relative intensities under various conditions with great precision." But it should be observed that the selection of the tints may be made at leisure, and under favourable laboratory conditions, and by thus avoiding all colour trouble during ordinary use of the photometer, a very considerable gain in precision is secured.

The scale is 5½in. (137mm.) long, and is shown in Fig. 3. With the smaller of the two lamps the highest reading is equivalent to one candle at a foot; with the larger lamp it is twice this illumination. The oscillations of the handle generally extend at first over two scale divisions, and after three or four oscillations their amplitude may be reduced to about one scale division. The half of a scale division may be estimated, except at the highest part of the scale, which is slightly contracted. The precision is about 2 to 3 per cent. The contraction of the scale at the upper end is intentional, and is caused by the arrangement of the levers.

In case of renewal of the lamps it is very important that other lamps should be placed in exactly the same optical position in the photometer, otherwise the scale would have to be recalibrated. In order to fix the height of the lamps, which is the only adjustment necessary, a sheet metal screen, shown by dotted lines in Fig. 1, is placed in a holder attached to the floor of the photometer. Two small holes are drilled in this screen, and a white paper screen, having a black horizontal line, is fastened to the end of the box (*see* Fig. 1) opposite to

Fig. 3.

the lamps. The hinged screen being lifted by the levers out of the way, "pin-hole images" of the filaments are thus thrown on to this screen, and the lamps being set so that the single horse-shoe filament appears nearly closed up (*see* Fig. 2), the dark line between its two limbs is made to fall on the black horizontal line. The images being magnified, considerable accuracy is possible.

Although the principal object of this photometer, as of those which preceded it, is the measurement of illumination, it is sometimes desirable to measure the candle-power of a lamp in a street without removing it from its position. By the use of a graduated arc such measurements can be made with the present photometer. A quadrant is fastened to the side of the photometer, and a pin at the centre from which the quadrant is struck acts as a gnomon. A spirit level on the top of the instrument being adjusted, the angle of incidence may be read in degrees on the quadrant, and at the same time the cosine of this angle may be read on an adjacent scale. It is necessary to find the slant height or direct distance from the source of light to the photometer.

To measure the vertical height of the light, set the photometer so that the shadow falls on 45deg. Measure the distance from the pin to the lamp horizontally, and from the pin to the ground vertically. The sum of these distances is the height of the actual source of light. This can be measured to about 2 per cent., say 3in. in 12ft. 6in.

To find the slant height at any distance, the height of the light being known: divide the height of the lamp above the photometer by the cosine of the angle of incidence; the quotient is the slant height required. Or the horizontal distance may be measured and the square of this distance added to the square of the height of the light. This gives the square of the slant height.

To find the candle-power, the illumination in units of a candle at a foot being observed, the light from other lamps being carefully screened, the slant height being known: multiply the illumination by the square of the slant height, and divide by the cosine of the angle of incidence.

On hilly ground it is necessary to know the height of the lamp above the photometer at each point of measurement. It is best, in that case, merely to record the angles, and afterwards to find the tangents. The horizontal distance between the photometer and the lamp-post, divided by the tangent, gives the required height. It may be observed that when the square of the slant height in feet is equal to the cosine of the angle of incidence, the scale graduated in units of a candle at a foot becomes a scale of candle-power, and when the square of the distance in feet is 10, or 100, or 1,000 times the cosine, the multipliers 10, 100, or 1,000 may be used to convert it into a scale of candle-power. The square of the slant height being known, the photometer may be tilted until the required cosine is indicated by the shadow of the pin. If the slant height is measured by the sum of the squares of the horizontal distance and the height, the square is at once obtained.

We have calibrated our photometers either by standard candles, or by sub-standard glow lamps supplied from secondary batteries, or by the amyl-acetate standard lamp or Hefner unit. This standard, which is well recognised in physical work, is 0·877 of a standard candle, or a standard

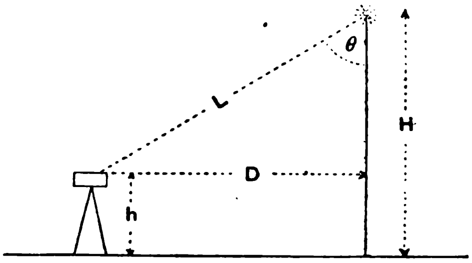

Fig. 4.

candle is 14 per cent. more than an amyl-acetate lamp. Placed at 1ft. distance from, and perpendicular to, the diaphragm, the photometer being placed on its side, the illumination is 0·877 of a candle at a foot. If it is brought to a distance of 11¼in. ($\sqrt{0{\cdot}877}$ft.), it is equivalent to 1 candle at a foot. But this distance and position is inconvenient. If it is placed at a distance of 1ft., and at an angle of 55° 10′, the illumination on the diaphragm is one-half of a candle at a foot, since cosine 55° 10′ = 0·57, and 0·57 × 0·877 = 0·5. A mark is therefore made at this angle on the quadrant, and is inscribed, H.U. = ½ c.p.

Considerable experience with the use of small glow lamps supplied from portable secondary batteries has given us great confidence in this kind of secondary standard of candle-power. The battery is always freshly charged before each evening's work, and is discharged for half an hour before use. The lamps are only turned on while an observation is being taken.

The 1893 photometer was arranged to be held in the hand; our 1884 photometer stood on a tripod about 2ft. 6in. from the ground. The street measurements made in 1892 were all made with a photometer placed on the ground, the diaphragm being about 6in. from the pavement. The proper height for an illumination photometer is a matter of opinion. When the photometer is placed on the ground, the large number of measurements required for a thorough photometric survey of a street or empty building can be quickly made. For some purposes—for example, in an exhibition or a church—a stand is necessary; the calculations of candle-power then become rather more tedious.

The various observed and computed quantities may be expressed as follows:—D = horizontal distance from photometer to lamp-post (*see* Fig. 4); L = slant height from photometer to

* Owing to the Purkinje effect, an exact colour match cannot be maintained throughout the whole range. The holes in the diaphragm look yellowish under strong illumination and bluish under feeble illumination.

† "A Treatise on Photometry." Palaz. American translation. Appendix, p. 312.

Digitized by Google

light; H = height of light above the ground; h = height of the photometer diaphragm from the ground; θ = angle of incidence; c/f^2 = illumination of units of a candle at a foot; c.p. = candle-power, then

$$H - h = D/\tan\theta;$$
$$L = [H - h]/\cos\theta = \sqrt{D^2 + [H - h]^2};$$
$$c.p. = (c/f^2 \times L^2)/\cos\theta.$$

The following is an example of the measurement of the illumination and candle-power in the case of a street lamp:—

D	θ	c/f^2	$\tan\theta$	$\cos\theta$	$H-h$	H	L	L^2	$c/f^2 \times \cos\theta$	c.p.

A PORTABLE MAGNETIC-FIELD TESTER.*

BY PROF. W. E. AYRTON, F.R.S., AND T. MATHER.

In June, 1892, the authors described a portable ballistic galvanometer of the moving-coil type before the Physical Society of London,† but owing to delay in the manufacture the instrument was not ready in time to be shown at the meeting. Since that time many experiments have been carried out with the instrument then described, and the galvanometer has been used to map out the stray fields of various dynamos, and to explore the magnetic fields in the neighbourhood of switchboards of electric light stations.

This first instrument possessed several structural defects, but the most serious faults experienced were, first, inconstancy of zero, and, second, a considerable want of proportionality between quantity and swing—or strength of field and swing of the needle—a proportionality which theoretically should hold for all angles of whatever magnitude. Eventually both these

FIG. 1.

difficulties were traced to magnetism in the suspended coil, a property which, although every care may be taken to prevent contamination of the material with iron, is very difficult to eliminate. After much experimenting, with a view to avoiding traces of magnetism in the suspended parts of swing-coil galvanometers, a satisfactory method was devised early in 1894, and a description of a reflecting galvanometer fitted with an improved coil appeared in the technical papers in the autumn of that year.‡ Meanwhile an improved form of the portable ballistic galvanometer had been prepared, in which the details of construction were considerably modified, so as to make the working parts more accessible, and an improved shape of coil was employed. For ballistic galvanometers the best shape of the cross-section of the moving coil is not the same as that for a current galvanometer, for whilst a current instrument should have a coil whose section approximates to two circles touching one another, a ballistic instrument is improved by using a sector-shaped coil of narrow angle, as shown in Fig. 1.

The instrument as now made is shown in Fig. 2, whilst Fig. 3 gives a sectional plan. A circular base provided with levelling screws carries a C-shaped magnet M (Fig. 3), between the poles of which the coil C is suspended. The discharges are led into and out of the coil by the suspensions, one being a straight phosphor-bronze strip, and the other a spiral surrounding the straight strip. Both suspensions are attached to an ebonite head near the top of the central tubes, this head serving the purpose of zero adjustment, and the arrangement is such that the whole of the suspended parts can be readily withdrawn.

The arm carrying the suspension head overhangs the scale, so as to permit of the pointer making one or more complete revolutions, and in this way an instrument having a very long range is obtained. For example, the body of the instrument shown in Fig. 2 has a diameter of 4in., and the length of the scale, reckoning only one revolution of the pointer, is about 11in. As it is quite possible to use $1\frac{1}{2}$ or 2 revolutions without straining the suspensions unduly, we have here an instrument with a scale as long as that of an ordinary reflecting galvanometer (18in.) in a very compact form.

To increase the range of the instrument still further, and to make the instrument suitable for measuring the stray magnetic

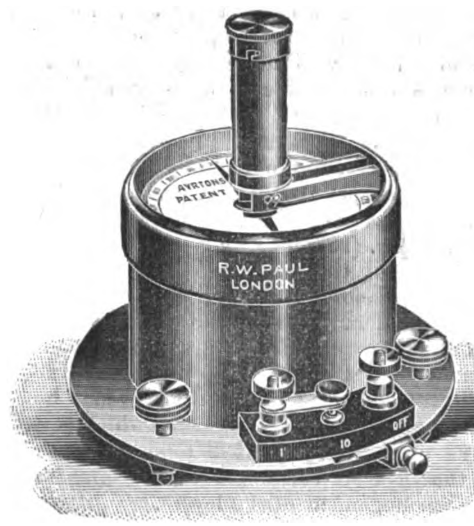

FIG. 2.

field in close proximity to dynamos, pole-pieces, &c., a switch, S (Fig. 3), is arranged to put a resistance coil R in series with the suspended coil, thus multiplying its range by 10. The same switch, when moved to the position OFF (Fig. 2) breaks the circuit of the instrument and lifts a spring, L (Fig. 3), which clamps the coil. A short-circuit key, K, on the front of the galvanometer is used to bring the pointer to rest, for when this is pressed the motion of the coil becomes aperiodic.

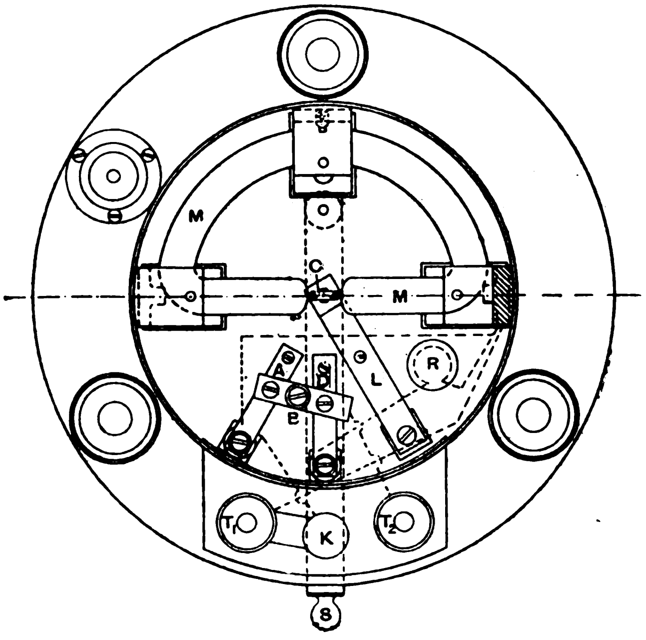

FIG. 3.—Sectional Plan.

The scale of the instrument is divided into 200 parts, and as a field tester the sensibility is such that with an appropriate test coil the scale reads off directly the strength of field in C.G.S. units.

For some purposes it is convenient to have the scale graduated in microcoulombs, in which case, besides reading the quantity directly, the swing of the instrument multiplied by the total resistance of the galvanometer circuit measures the

Digitized by Google

total change of induction through that circuit. Such a scale is useful in testing iron for permeability, &c., for by suitably arranging the resistance of the circuit the scale reading can be made to read off B, the induction density, directly.

Theory of Portable Field Tester.

Let H = strength of magnetic field in C.G.S. units;
n = number of turns in coil;
r = mean radius in centimetres of coils projected on medial plane;
l = mean length of each coil, supposed rectangular;
I = moment of inertia of moving parts;
ω = angular velocity imparted to coil by discharge;
α = torque exerted by suspension when twisted through unit angle;
N = total change of flux through circuit;
R = resistance of the circuit.

Then, assuming that the plane of the coil is parallel to the field of magnet when the discharge passes, we have—

Moment exerted by the coil at any instant

$$= r\,l\,n\,\mathrm{H}\frac{d\mathrm{N}}{dt}\,\frac{1}{\mathrm{R}} \quad . \quad . \quad . \quad . \quad . \quad (1)$$

$$= y\frac{d\mathrm{N}}{dt}\ \text{(say)} \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

therefore angular impulse $= \int y\frac{d\mathrm{N}}{dt}\,dt \quad . \quad . \quad . \quad . \quad . \quad (3)$

$$= y\,\mathrm{N} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

This must be equal to the angular momentum imparted to the coil, hence

$$\mathrm{I}\,\omega = y\,\mathrm{N} \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

Now, the energy stored in the coil at the completion of the discharge is

$$\frac{\mathrm{I}\,\omega^2}{2},\ \text{and is therefore} = \frac{\mathrm{I}}{2}\left(\frac{y\,\mathrm{N}}{\mathrm{I}}\right)^2 \ \text{from (5)}$$

$$= \frac{y^2\,\mathrm{N}^2}{2\,\mathrm{I}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

Now, all this energy is expended in twisting the suspensions through an angle, ϕ, where ϕ is the swing of the pointer. But the work done in the process is

$$\int_0^{\phi} \alpha\,\theta\,d\theta$$

$$= \frac{\alpha\,\phi^2}{2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

Equating (6) and (7) we have

$$\frac{\alpha\,\phi^2}{2} = \frac{y^2\,\mathrm{N}^2}{2\,\mathrm{I}},$$

from which

$$\phi = \pm\frac{y}{\sqrt{\alpha\,\mathrm{I}}}\,.\,\mathrm{N};$$

i.e., ϕ is proportional to N.

Table *showing Calculated Swings produced by discharging a Constant Quantity of Electricity through a single turn of Wire bent to four coils of Various Shapes.*

Assuming: 1st, constant magnetic field; 2nd, constant control; 3rd, constant length of wire in coil; 4th, constant diameter of wire in coil; 5th, no added mass.

Shape.	Proportions.	Swing.	Relative moment of inertia.
Rectangular.........	length = breadth × ∞	100·0	0·0
„	l = 10 b	91·0	2·32
„	l = 2 b	75·6	23·1
Square	l = b	61·0	50·0
Circular	—	71·0	60·7
Rectangular.........	2 l = b	45·0	68·1
„	10 l = b	11·5	97·6
„	∞ l = b	0·0	100·0

Herewith we give a table showing the relative swings produced by discharging a given quantity of electricity through a given length of wire wound into coils of various shapes. From this it will be seen that the long narrow coil has considerable advantage over common shapes as regards sensibility. At the same time it permits of much greater range than the forms which necessitate the use of a central core in order to obtain the requisite strength of field to give good shielding from external disturbing fields. The use of a narrow coil also enables swings to be taken in either direction without reducing the range, whereas instruments with cores necessarily have their maximum range of 180deg. reduced to something less than 90deg. if arranged to read either right or left of zero.

PROF. L. F. VERNON-HARCOURT'S PRESIDENTIAL ADDRESS TO SECTION G.

[ABSTRACT.]

THE RELATION OF ENGINEERING TO SCIENCE.

It has appeared to me that the exceptional occasion of addressing a gathering of scientific persons, and of engineers who testify their interest in science by attending these meetings, would be best utilised by considering the relation that engineering in general, and maritime and hydraulic engineering in particular, bear to pure science, and the means by which progress in engineering science might be best promoted, and its scope and utility increased.

In addition to the oft-quoted definition of civil engineering as "the art of directing the great sources of power in Nature for the use and convenience of man," Thomas Tredgold also defined it, in 1828, as "that practical application of the most important principles of natural philosophy which has, in a considerable degree, realised the anticipations of Bacon and changed the aspect and state of affairs in the whole world." If the influence of engineering could be thus described in 1828, when railways and steamships were in their infancy, and the electric telegraph and the various modern applications of electricity and magnetism had not come into existence, how far more true is it at the present day, when the various branches of engineering have attained such a marvellous development! Moreover, Tredgold foresaw the great capabilities of development possessed by engineering, and its dependence on science; for he stated that "the real extent to which civil engineering may be applied, is limited only by the progress of science; its scope and utility will be increased with every discovery in philosophy, and its resources with every invention in mechanical or chemical art, since its bounds are unlimited, and equally so must be the researches of its professors." If the full significance of these statements may be accepted as correct, engineers might fairly claim to have a right to say, "As engineers we are necessarily men of science, and no branch of science is outside our province." It might, however, be said that no engineer, with his absorbing professional avocations, would have the time to acquire even the rudiments of the principal branches of science, with their ever-increasing developments, to the study of each of which the life-work of many earnest searchers into the secrets of Nature is wholly devoted. Among the branches of science necessary for the engineer, two may be regarded as of the highest importance, namely, mathematics and physics, upon which the science of engineering mainly depends; and without an adequate knowledge of these no person should be able at the present day to enter the profession of a civil engineer. Other sciences of considerable, though of comparatively minor importance to engineers in general, are chemistry, geology, and meteorology; but each of these assumes an enhanced value in special branches of engineering.

Mathematics in Relation to Engineering.—The pre-eminent importance of mathematics in relation to engineering may be accepted as fully established; and a President of the Institution of Civil Engineers would not now tell a pupil, at their first interview, that he had done very well without mathematics, a remark made to me by a justly celebrated engineer over 30 years ago. All branches of applied mathematics have been utilised by engineers, or, as in the case of several general principles and tidal calculations, by mathematicians to their benefit; but graphic statics will probably gradually supersede analytical methods for the calculation of stresses, as more rapid in operation and less subject to errors, which are also more easily detected in graphic diagrams. Pure mathematics, in its higher branches, appears to have a less direct connection with engineering; but applied mathematics is so largely dependent upon pure mathematics that the latter, including the calculus and differential equations, cannot be safely neglected by the engineer, though certain branches, as, for instance, probabilities, the theory of numbers, the tracing of curves, and some of the more abstruse portions of the subject, may be dispensed with.

Physics in Relation to Engineering.—Physics has been placed after mathematics, as many physical problems are determined by mathematics; but in several respects physics, with its very wide scope in its relation to the various properties of matter, is of equal importance to engineers, for there are few problems in engineering

Digitized by Google

in which no part is borne by physical considerations. Electrical engineering is very intimately connected with physics, for it really is the application of electricity to industrial purposes. The very close relation between electricity and magnetism, discovered by Oersted in 1820, and further established by the remarkable researches of Faraday, has led to the present system of generating electricity by the relative movement of coiled conductors and electro-magnets, in dynamo-electric machines worked by a steam engine or other motive power. The electrical current thus generated can be transmitted to a distance with little loss of energy, and it can either be used directly for lighting by arc or incandescent lamps, or be reconverted into mechanical power by the intervention of another dynamo. Electricity is also employed for the simultaneous firing of a series of mines at a safe distance from the site of the explosion.

The manufacture of iron, steel, and other metals, and the formation of alloys, are essentially chemical operations; and the Bessemer and Gilchrist processes, by which steel is produced in large quantities directly from cast iron, by eliminating a portion of the carbon contained in it, and also the injurious impurities, silicon and phosphorous, in place of the former costly and circuitous method of removing the carbon from cast-iron to form wrought-iron, and then combining a smaller proportion of carbon with the wrought-iron to form steel, are based on definite chemical changes, and necessitated chemical knowledge for their development.

Cements and mortars depend for their strength and tenacity, when mixed with water, upon their chemical composition and the chemical changes which occur. The value of Portland cement requires to be tested quite as much by a chemical analysis of its component parts, as by the direct tensile strength of its briquettes; for an apparently strong cement may contain the elements of its own disruption, in a moderate proportion of magnesia or in an excess of lime. The chemical change which has been found to occur in the Portland cement of very porous concrete exposed to the percolation of sea water under considerable pressure, by the substitution of the magnesia in sea water for the lime in the cement, if proved to take place even slowly under ordinary circumstances, would render the duration of the numerous sea works constructed with Portland cement very precarious, and necessitate the abandonment of this very convenient material by the maritime engineer.

Benefits conferred by Engineering upon Pure Science.—Engineering is generally concerned in the application of the researches of science for the benefit of mankind, and not in the extension of the domain of pure science, which necessitates greater concentration of attention and study than the engineer in practice in able to devote to it. Engineers, however, though never able to repay the ever-increasing debt of gratitude which they owe to past and present investigators of science, except in rendering these abstract researches of practical utility, have, nevertheless, been able incidentally to promote the progress of science. Thus mechanical science, by the construction of calculating machines, the planimeter, integrating machines, the tide predictor and tidal harmonic analyser of Lord Kelvin, the self-registering tide-gauge, and various other instruments, has lightened the labours of mathematicians; whilst excavations for works and borings have assisted the investigations of geologists. The mechanical genius of Lord Rosse led mainly to the success of his gigantic telescope, which has revealed so many secrets of the heavens; and the rapidity of locomotion, due to the labours of engineers, has greatly facilitated astronomical observations and physical discoveries, besides promoting the concourse of scientific men and the diffusion of knowledge. Electrical engineering, moreover, is so closely allied to electrical physics that the development of the one necessarily promotes the progress of the other. The observations, also conducted by hydraulic and maritime engineers in the course of their practice, aid in extending the statistics upon which the science of meteorology is based.

Engineering as an Experimental Science.—Engineering, so far as it is based on mathematics, is an exact science, and the strains due to given loads on a structure can be accurately determined; but the strength of the materials employed has to be ascertained before any structure can be properly designed. Accordingly, the resistance of materials to tension, compression, and flexure, has to be tested, and their limit of elasticity and breaking weight determined. Thus, previously to the construction, by Robert Stephenson, of the Britannia Tubular Bridge, the first wrought-iron girder bridge of large span erected, numerous experiments on various forms of wrought iron were carried out by that eminent mathematician and mechanician Eaton Hodgkinson, who had previously indicated the proper theoretical form for cast-iron girders, and to whom the success of the bridge across the Menai Straits was in great measure due. Besides the numerous tests always now made of the materials employed during the progress of any large engineering work, railway bridges are also subjected to severe test loads before being opened for public traffic, by which the safety of the structures and their rigidity, as measured by the amount of deflection, are ascertained, serving as a guide for subsequent designs. Numberless experiments have been made on the flow of water in open channels, over weirs, through orifices, and along pipes; and the influences of the nature of the bed, the slope, depth, and size of channel, have been investigated by various hydraulicians. Mr. Thomas Stevenson measured the force of waves at some places on the Scotch coast; Professor Osborne Reynolds has examined the laws of tidal flow in a model of the inner estuary of the Mersey, and in specially shaped experimental models; and I have found it possible in small working models of the Mersey and Seine, not merely to reproduce the configuration of the bed of the estuary out at sea, but also to observe the effects of different forms of training works in modifying sandy estuaries. Mr. William Froude, after his retirement from active practice, devoted his abilities to experiments on the motion and resistance of ships in water, which have proved of inestimable value to the naval architect, and which formed the subject of his Presidential Address to this Section in 1875. Electrical engineering is specially adapted for experimental investigation, and in this branch theory and practice are so closely allied that some of the most eminent exponents of the theory of the subject, such as Lord Kelvin and Dr. Hopkinson, have developed their theories into practical results. In most other branches the investigator is generally distinct from the engineer in large practice; but it may be safely said that an able investigator and generaliser in engineering science, as, for instance, the late Prof. Rankine, accomplishes work of more value to the profession at large than the practical engineer, who, in the world's estimation, appears the more successful man.

Every branch of engineering science is more or less capable of being advanced by experimental investigations; and when it is borne in mind that the force of waves, the ebb and flow of tides in rivers, the influences of training works in estuaries, and the motion of ships at sea have been subjected to experimental research, it appears impossible to assign a limit to the range of experiments as a means of extending engineering knowledge. Problems of considerable interest, which can only be solved by experiments or by comprehensive generalisations from a number of examples, must frequently present themselves to engineers in the course of their practice, as they have to myself; and engineers would render a great service to the profession if they would follow up the lines of investigation thus suggested to them, in the true spirit of scientific inquiry.

Scientific Training of Engineers.—In most professions, preliminary training in those branches of knowledge calculated to fit a student for the exercise of his profession is considered indispensably necessary; and examinations to test the proficiency of candidates have to be passed as a necessary qualification for admission into the Army, Navy, Church, Civil Service, and both branches of the law. Special care is taken in securing an adequate preliminary training in the case of persons to whom the health of individuals is to be entrusted, not merely by experience in hospitals, but also by examinations in those branches of science and practice relating to medicine and surgery, before the medical student can become a qualified practitioner. If so much caution is exercised in protecting individuals from being attended by doctors possessing insufficient knowledge of the rudiments of their profession, how much more necessary should it be to ensure that engineers are similarly qualified, to whom the safety and well-being of the community, as well as large responsibilities in regard to expenditure, are liable to be entrusted! The duty of the engineer is to apply the resources of nature and science to the material benefit and progress of mankind; and it, therefore, seems irrational that no guarantee should be provided that persons, before becoming engineers, should acquire some knowledge of natural laws, and of the principles of those sciences which form the basis of engineering. The Institution of Civil Engineers has, indeed, of recent years required some evidence of young men having received a good education before their admission into the student class; but some of the examinations accepted as sufficient for studentship, such as a degree in any British university, afford no certainty in themselves that the persons who have passed them possess any of the qualifications requisite for an engineer; and it is quite unnecessary to become a student of the Institution in order to become an engineer. The Council of the Institution has no doubt been hitherto deterred from proposing the establishment of an examination in mathematics and natural science, as a necessary preliminary to becoming an engineer, by the remembrance that some of the most distinguished engineers of early days in this country were self-taught men; but since those days engineering and the sciences upon which it is based have made marvellous advances; and in view of these developments, and the excellent theoretical training given to foreign engineers, it is essential that British engineers, if they desire to retain their present position in the world, should arrange that the recruits to their profession may be amply qualified at their entrance in theoretical knowledge, in order to preserve the standard attained, and to be in a position to achieve further progress. No amount of preliminary training will, indeed, necessarily secure the success of an engineer, any more than the greatest proficiency would be certain to lead the medical student to renown as a physician or surgeon; but other conditions being equal, it will greatly promote his prospects of

Digitized by Google

advancement in his profession, and his utility to his colleagues and the public. The engineers of the past achieved great results in the then early dawn of engineering knowledge by sound common sense, a ready grasp of first principles and of the essential points of a question, capacity for acquiring knowledge, power of managing men and impressing them with confidence, and shrewdness in selecting competent assistants. These same qualities are still needed for success in the present day, coupled with an opportunity of exhibiting them; but far more knowledge of mathematics and other sciences is required now, owing to the enormous advances effected, if the progress of engineering science is to be maintained. Even though in some branches engineers in large practice may not have the time, or retain the requisite facility, for solving intricate mathematical problems, they should be able readily to comprehend the full bearing of the principles presented, and to understand the nature of the solutions put before them, which nothing but the scientific faculty implanted by early training in mathematics and physics can adequately secure. A qualifying examination for engineers would usefully stop persons at the outset from entering the profession who failed to evince the possession of the requisite preliminary knowledge; it would indicate, by the subjects selected, the kind of training best calculated to fit a person to become a useful engineer; and it would protect the public, as far as practicable, from the injuries or waste of money that might result from the mistakes of ill-qualified engineers.

Specialising in Engineering.—Some branches of engineering have for a long time been kept distinct from others, such as the construction of steam engines, locomotives, and marine engines, shipbuilding, heavy ordnance, hydraulic machinery, and other purely mechanical works, one or more of which have been treated as specialities by certain firms, and also gas lighting, and, more recently, electric lighting. In the department, however, of civil engineering in its narrower signification, as distinguished from mechanical engineering, engineers of former times were regarded as equally qualified to undertake any of the branches of public works; and the same engineer might be entrusted with the execution of roads, railways, canals, harbours, docks, sewerage works and waterworks; while even steamships were not excluded from the category in Brunel's practice. The engineer of to-day, indeed, would be lacking that important factor for success, common sense, if he declined to execute any class of work which he might be asked to undertake; and a variety of work is very useful to the engineer in enlarging his views and experience, as well as in extending the range of his practice. The tendency, however, now in engineering, as in medicine, is for the engineer's practice to be confined to the special branch in which he has had most experience, a result which cannot fail to be beneficial to the public, and calculated to promote the progress of each branch. The powers of the human mind are too limited, and life is too short, for engineers to be able to acquire, in the present day, equal proficiency in the theory and practice of the several branches of engineering science, with their ever-widening scope and development; and, as in the domain of abstract science, general progress will be best achieved in engineering science by the concentration of the energies of engineers in the advancement of their special line of practice.

Value of Congresses on Special Branches of Engineering.—The scope of engineering science is extending so fast that it is impossible for the Institution of Civil Engineers, which, as the parent society, embraces every branch within its range of subjects, to give more than a very limited time for the consideration and discussion and of Papers relating to the non-mechanical branches of the profession comprised in public works. Mechanical, electrical, and gas engineers have special societies of their own for advancing their knowledge and publishing their views and experience, while sharing equally with the other branches in the benefits of the older Institution. Congresses accordingly afford a valuable opportunity for railway, hydraulic, and sanitary engineers of expressing their views, and enlarging their experience by consultation and discussion with engineers of various countries. My experience of the six maritime, inland navigation, and waterworks international congresses I have attended in England and abroad, has convinced me of the very great value of such meetings in collecting information, comparing views, and obtaining some knowledge of foreign works and methods; whilst the acquaintances formed with some of the most celebrated foreign engineers afford opportunities of gaining further information about works abroad, and deriving experience from their progress and results.

Engineering Literature.—Lawyers have been defined as persons who do not possess a knowledge of law, but who know where to find the law which they may require. It may be hoped that a similar definition is not applicable to engineers; but with the rapid increase of engineering literature it is most desirable that engineers should be able readily to refer to the information on any special subject, or descriptions of any executed works, which may have been published. Much valuable matter, however, is buried in the *Proceedings* of engineering and scientific societies, and in various publications, and often a considerable amount of time is expended in fruitless search. This great waste of time and energy, and the loss of available information involved, led me a few years ago to suggest that a catalogue of engineering literature ought to be made, arranging the lists of publications relating to the several branches under separate headings. There is a possibility that this arduous and costly task may be partially accomplished in separate volumes, and, at any rate, the first step has been effected by the publication, under the auspices of the Paris Inland Navigation Congress of 1892, of a catalogue of the publications on inland navigation. A start has also been made in France, Italy and England towards the preparation of a similar catalogue on maritime works, which it may be hoped means will one day be found to publish on the meeting of some future congress. Engineers who have searched, even in the best libraries, for the published information on any special subject will appreciate what a great boon an engineering subject catalogue would be to the profession, and indirectly to the public at large.

Concluding Remarks.—In this address, I have endeavoured, though very imperfectly, to indicate how engineering consists in the application of natural laws and the researches of science for the benefit and advancement of mankind, and to point out that increased knowledge will be constantly needed to keep pace with, and to carry on, the progress that has been made. The great advantages provided by engineering works in facilitating communications and intercourse, and consequently the diffusion of knowledge, in increasing trade, in extending civilisation to remote regions, in multiplying the comforts of life, and affording enlarged possibilities of enjoyment and change of scene, may be regarded as amply acknowledged; but the more gradual and less obvious, though not less important, benefits effected by engineering works are not so fully realised.

A comparison of engineering with the other chief branch of applied science, medicine, exhibits some similarities and differences. In both professions, the discoveries of science are utilised on behalf of mankind; but whilst physicians devote themselves mainly to individuals, engineers are concerned in promoting the well-being of the community at large. Persons reluctantly consult doctors when they are attacked by disease, or incapacited by an accident; but they eagerly resort for enjoyment to railways, steamships, mountain tramways, piers, great wheels, and Eiffel towers; and they frequently avail themselves of the means of cheap and easy locomotion to complete their restoration to health by change of air and climate. Physicians try to cure people when they are ill; whereas engineers endeavour, by good water-supply and efficient drainage, to maintain them in health; and in this respect, the evident results of medical skill are far more readily realised than the invisible, though more widespread, preventive benefits of engineering works. Statistics alone can reveal the silent operations of sanitary works; and probably no better evidence could be given of the inestimable value of good water and proper drainage on the health of the population of large towns, when aided by the progress of medical science, than the case of London, where, towards the close of the last century, the death-rate exceeded the birth-rate, and the numbers were only kept up by constant immigrations; whereas now, in spite of the vast increase of the population and the progressive absorption of the adjacent country into the ever-widening circle of houses, the number of births exceed the deaths by nearly 900 a week.

The remarkable triumphs of engineering have been due to the patient and long-continued researches of successive generations of mathematicians, physicists, and other scientific investigators, and it is by the utilisation of these stores of knowledge and experience that engineers have acquired renown. A higher tribute of gratitude should perhaps be paid to the noble band of scientific investigators who, in pursuit of knowledge for its own sake, have rendered possible the achievements of engineering, than to those who have made use of their discoveries for the attainment of practical benefits; but they must both be regarded as co-workers in the promotion of the welfare of mankind. The advancement of science develops the intellectual faculties of nations, and enlarges their range; whilst the resulting progress in engineering increases their material comforts and prosperity. If men of science, by closer intercourse with engineers, could realise more fully the practical capabilities of their researches, and engineers, by a more complete scientific training, could gain a clearer insight into the scientific aspect of their profession, both might be able to co-operate more thoroughly in developing the resources of nature, and in furthering the intellectual and material progress of the human race.

Destroying Insects by Electricity.—Some successful experiments for destroying moths, &c., in forests were made a little while ago in Saxonia. A revolving search light was erected and set to work. Large numbers of insects were attracted and were then killed by an incandescent platinum screen, which was fixed around the lamp.

The Electrician.

The Oldest Electrical Journal (1861—1878.)

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny
Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	YEAR.	HALF-YEAR.	QUARTER.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to* **4** *p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of*—

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

THE WORK OF HERTZ. By Dr. O. J. LODGE. Price 2s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. [*In preparation*

SPECIAL NOTICE.

With last week's number of "THE ELECTRICIAN" was issued a Fine STEEL PLATE PORTRAIT of WILLIAM STURGEON. This Supplement was issued gratis, and complaints of non-receipt should be sent immediately to the Publisher.

NOW READY.—Vol. XXXIV. of "THE ELECTRICIAN," bound in strong cloth. Price 12s. 6d., post free 13s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

EXHIBITIONS.

As secretary of the Society of Arts, which originated the very idea of industrial exhibitions, and as one having an unique experience of modern raree-shows, something more definite and conclusive might reasonably have been expected from the pen of Sir HENRY TRUEMAN WOOD than is discoverable in his recent letter to *The Times*. As an historical retrospect the letter is not without interest, but it contains nothing whatever in the shape of ripe counsel, and ends in a piece of empty flattery of our good friends the French. The individual manufacturer, as distinguished from the pseudo-manufacturer, who mainly sells goods of other people's make, has probably long ago made up his mind that, so far as he is immediately concerned, exhibitions are a costly mistake. When, however, one comes upon two or more manufacturers gathered together for the purpose of considering the advisability of recommending their particular trade to hold aloof from this or that proposed exhibition, considerable hesitancy is displayed by them, notwithstanding their almost invariable individual experience of the futility of exhibiting. Nor is it very difficult to see whence this state of indecision arises. There is a vague feeling abroad that the splash made by an exhibition does good on the whole, although those who actually help to make the splash may never see any tangible return for their outlay. Hence the disinclination to take part oneself in any given exhibition is beautifully balanced by a desire to see someone else do so; and this again is dashed with misgiving, lest after all this someone else may be the exception that proves the rule, and instead of altruistically benefiting the trade at large may reap a fine harvest for himself. The natural resultant of all these component

Digitized by Google

perplexities is a general grumble followed by a general rush to get places. Now it is right here, as our American relations express it, that the industrial community would be glad to have the truth, the whole truth and nothing but the truth about exhibitions from a veteran Royal Commissioner like Sir Henry Trueman Wood. Instead of this, the best part of a column of our leading daily paper is devoted to a mere historical *résumé*, with just a hint of a personal preference for "smaller exhibitions." The genuine idea of exhibition has, we are told, and indeed are well aware, "developed in a wrong and unfortunate direction." Originally these shows were intended to be "collections illustrative of material and industrial progress," to bring to the notice of the public the latest thing in each department of industry, to afford "opportunity for comparison." But the novelty of these huge aggregations of industrial products soon wore off, and—though Sir Henry Wood does not take this factor into account—the belief that production was the whole duty of man soon faded, and in consequence the £200,000 surplus of the Exhibition of 1851 has been the only thing of the kind. It was at this juncture that Sir Philip Cunliffe Owen came forward with that happy thought—that insidious idea—of adding "a judicious flavouring of amusement" to the exhibitional ingredient. We know the result. To-day, as Sir Henry Wood truly puts it, the chief use of industrial exhibits is "to lend an air of respectability" to a mere raree-show. Having arrived by due process of evolution at this stage of development, one would have thought that the logical outcome would be to apply the surgeon's knife and lop off the now useless industrial member. The Secretary of the Royal Commission for the Chicago Exhibition is not, however, quite sure "what special conclusion is to be drawn from these considerations."

The purpose of an ordinary industrial exhibition is twofold—to educate the public and enlighten the members of the industrial section of the community as to what each member of it is doing and how he does it. Well, it is tolerably clearly realised in these days: firstly, that the public does not want to be educated, at any rate in this particular way; secondly, that the last thing an exhibitor cares to do is to enlighten a competitor. The whole *raison d'être* of the "serious" exhibition has therefore, so to speak, become converted into a very good reason for its non-existence. But "shall there be no more cakes and ale"? Far from it. We would suggest that the electrical industry, at any rate, would do well to supply the public demand for these commodities. The iron trade or the textile trade indeed might find it somewhat difficult to attract public attention through the medium of the public's amusements. But an electrical Kiralfy would esteem it an easy task to convert an entire exhibition, so called, into one long display of the capabilities of electricity—and why not? A lavish use of search lights, arc lamps, glow lamps, and illuminated fountains would serve to exhibit one aspect of the subject. Then trips in electric trams, gondolas, and launches, swings in electric cranes, and hoists in electric lifts might bring home to the mind exactly what the electric motor can do when put to it. All cooking would, of course, be done electrically, and concert halls and theatres would be connected up telephonically. Miniature waterfalls would illustrate the possibilities of the electric transmission of power, and realistic, well-lighted coal mines would set forth the many virtues of electric pumping, hauling and coal-cutting. There need be no pretence to solemnity, no awe-inspiring stands filled with unintelligible exhibits, no business-like advertisement placards, but merely "sixteen hours' continuous amusement." Education, though not the ostensible object of Electrical Utopia, would be a result. When the public has no long-felt wants it is the business of the manufacturer to supply it with a few. All the electrical paraphernalia of A.D. 1895 are as naught, unless the public can be pleasantly persuaded into purchasing.

THE BRITISH ASSOCIATION AT IPSWICH.

Thursday, September 12th.

The Sectional Meetings commenced with a grand total of about 1,150 visitors, which, while much smaller than the corresponding total at the opening of the Oxford meeting last year, was a marked improvement upon the number of visitors at the last Ipswich meeting.

In Section A, the address by Prof. W. M. Hicks on ether structure called forth appreciative remarks from Lord Kelvin, Prof. FitzGerald and others. Lord Kelvin remarked on the high degree of satisfaction with which we may view the fact of the structure and dynamical functions of one and the same ether providing explanations of so diversified a range of physical and chemical actions; and he looked forward to the time when electrical, chemical, gravitational and every physical action could be explained by some hypothesis of a universal medium or ether, and to the far-distant time when every one of the questions proposed by Prof. Hicks would be answered. Prof. FitzGerald called attention to the curious dilemma that the hypothesis of a vortex-ether explanation of Nature involved. There should, he said, be both positive and negative *matter*, a set of positive hydrogen atoms, and a set of negative hydrogen atoms; and he remarked that it has been sought to dispose of this dilemma by conceiving that only *one* kind of each elementary atom is known to us in this material universe, the opposite kinds of all the elements having been repelled—by negative gravity—to some unknown and infinitely distant universe of worlds!

The first Paper read in Section A was by the President, Capt. Sir Douglas Galton, who happily had quite recoved from his indisposition of the previous evening. This Paper, or "Memorandum on the Reichsanstalt, Charlottenburg," had for its main object the appointing of a Committee, who should be charged with the duty of approaching the British Government with a view to the creation of a similar institution in this country. The Reichsanstalt is, in its chief department, an institution for the pursuit of pure scientific research. A subsidiary department engages in the work of testing and commercial research. Sir Douglas suggested, as one solution of the problem, that Kew Observatory should be extended and amplified, so as to cover the range of pure research in addition to its present normal functions. A most interesting debate, in which many competent speakers took part, followed the reading of this Paper. The general consensus of opinion was that in the matter of pure research Britain is far behind Germany; and a cry was raised for more complete organisation of research in this country. To this opinion Lords Kelvin and Rayleigh, and Profs. Ayrton, FitzGerald, Thompson and others, gave unanimous voice. There were, however, differences of opinion as to the *modus operandi*. Some thought that the support of pure research should come directly from the State, which should be asked to provide lands, buildings and funds; some few, headed by Prof. FitzGerald were disposed to throw the duties upon the existing Universities; while Prof. Ayrton spoke a timely note of warning when he pointed out the utter hopelessness of State aid, until it shall have been shown to the Government and the nation that pure research is of as great national importance as the building of warships. It was also pointed out that the attitude of the British Government towards scientific research, as well as music, literature and the drama, was essentially different from that of Continental Governments; and that, unless scientific research could show a better cause that the others, it stood only an equal chance with them of State patronage.

Meanwhile, in Section G, the Presidential Address by Prof. L. F. Vernon Harcourt, on "The Relation of Engineering to Science," was read, and was succeeded by a highly debatable

Digitized by Google

Paper on "Light Railways as an Assistance to Agriculture," which was read by Major-Gen. Webber. The author advocated the introduction of light railway lines along the side of country roads, connecting farm with farm and market; and he pronounced this course to be one likely to ameliorate the state of agriculture. His lines would not in any sense be feeders to main railway lines; nor was it proposed that they should be built so as to have any prospect of being used as main lines. They were essentially road lines. A long and brilliant discussion ensued, during part of which a mimic "battle of the gauges" was fought. Perhaps the best thing was said by Mr. W. Worby Beaumont, who pointed out that it was futile to discuss questions of gauge and the relative merits of steam, cable, electricity, &c., until radical improvements had been made in the financial machinery for bringing such railways into existence.

Friday, September 13th.

Electrical Papers were conspicuous by their absence on Friday, and the nearest approach made to a topic of electrical interest was when the combined Sections A and B debated "On the Evidence to be gathered as to the Simple or Compound Character of a Gas, from the constitution of its Spectrum." Prof. Schuster opened the discussion, and during his remarks made the interesting statement that he considered all evidence based on vacuum tube and spark discharge to be excluded; his reason being that under either of these conditions the behaviour of the gas, and therefore the character of its spectrum, might be abnormal. There was no saying what influence and electrical discharge might have on the behaviour of the gas. Prof. Runge followed with an interesting hypothesis of the compound nature of helium, based upon the duality of its spectrum. An attempt was made by Dr. Johnstone Stoney to give greater weight to the importance of the German methods of research, by insisting that there is not anywhere in the United Kingdom facilities for carrying on such researches as those of Prof. Runge. But the point of these remarks was turned by Prof. Armstrong, who briefly announced that Prof. Runge's researches had not been conducted under State aid, but had been carried on at the investigator's personal expense; and that it was open to anyone in the United Kingdom to "go and do likewise."

In the evening the Association met in the Public Hall, to listen to an able and interesting lecture by Prof. Silvanus P. Thompson, on "Magnetism in Rotation." The lecturer sketched, in his inimitable style, the development of the rotatory magnetic field and its uses, from the starting point of Arago's discoveries of the influence of metallic masses on moving magnets. The subject was pursued down to its latest and most commercial developments, as well as in the direction of a plausible hypothesis of terrestrial magnetism and earth currents. The practical side of the subject was illustrated by means of a three-phase generator and polyphase motor, the latter being coupled to various useful implements, including a coffee mill and a mangle.

Saturday, September 14th.

An inspection of the *Journal* for Saturday made it apparent that this day had been selected to bear the chief burden of the scarcity of Papers. Many of the Sections did not assemble, and in Section G there was only one Paper of electrical interest. This was read by Mr. J. Napier, the Public Analyst for the County of Suffolk, and dealt with the Hermite sewage deodorising process, now being tried at Ipswich. The particulars of this process are known to our readers, and it will be sufficient if we notice the modifications of the complete process which have been adopted at Ipswich. Instead of supplying the deodorising liquid—the Hermite liquid—to every house, and passing it through every branch drain and sewer, the liquid is merely caused to flow, from an up-town inlet, through the main sewer and discharge itself with the sewage at the sea outfall. Thus it is used only as a main flush. In the discussion which followed, the impression seemed to prevail that the Hermite process is one intended only for application to ancient and defective sewage systems as a less expensive remedy than the complete reconstruction of the sewers. This misapprehension we hasten to correct, as the Hermite process, if it is useful at all, is equally of use in modern and perfect sewage systems as in old and defective ones. Its value lies in the treatment of sewage at the earliest possible stage.

Monday, September 16th.

Monday was "electrical day" in Section G, and a lengthy programme was arranged for that day. The proceedings were opened by Mr. P. Dawson, who read a lengthy and interesting Paper on "The Modern Application of Electricity to Traction Purposes." The author briefly sketched the various systems which are now well established, but he devoted his chief time and attention to the advocacy of the overhead trolley system. Instructive comparisons were made between the abundant development of electric traction on the Continent and in America, and the paucity of development at home. Mr. Blackwell followed with some remarks, during which he insisted that the chief reason for the tardiness of electric tramways in England was due to the feeble patronage that tramways as a class received in this country. The social status of the tram-car required to be elevated. Mr. J. Head gave some account of what he had seen in America; and another speaker described the principal features of the system in use in the Isle of Man.

The next Paper, which was read by Mr. Trotter, and was contributed by Mr. W. H. Preece and Mr. Trotter, was on the subject of "An Improved Portable Photometer." A reprint of this Paper, with a report of the discussion which followed its reading, will be found elsewhere in our columns. The speakers in the discussion insisted on the importance of seeking to obtain, not only the right kind and amount of light, but the right distribution of it; and municipal bodies were advised that the distribution of illumination in an efficient manner, in streets and public places, was a too much neglected matter, to which more attention should be paid by them if they desire to get the most for their money.

A Paper by Mr. H. A. Earle, on "Storage Batteries," came next, and its main object was to point out the merits of the latest forms of secondary practice, as illustrated by the chloride cell. Speakers in the discussion were unanimous in the opinion that this form of cell is admirably adapted to the severe conditions of electric traction, whether in battery cars or in battery stations connected to conductor systems. A description of the use of these cells was given by Major-Gen. Webber, and others spoke on the same subject.

In a Paper on "The Development of the Telephone Service in Agricultural Districts," read by Major-Gen. Webber, it was sought to show that a great deal of the present condition of agricultural depression is due to the fact that your yokel cannot telephone to market or from village to village; and it was advocated that if he could get three minutes' talk for twopence, as it was attempted to show he might, he would soon become a happy and a prosperous yeoman. The speakers who took part in the debate were of a less sanguine condition of mind in regard to this matter; and they failed to see that what the telegraph had failed to do, the telephone was sure to accomplish, or to believe that the state of depression partially due to the former would be eradicated on the advent of the latter.

The last Paper read was by Mr. A. R. Bennett, on "Some Lessons in Telephony"; and in tone and substance it was a jeremiad on the awful state of this country as compared with foreign countries, as regards telephonic communication.

(To be continued.)

Electric Headlights.—Electric lights, says the *Electrical Engineer* of New York, will soon succeed oil lamps as headlights on all of the passenger train locomotives of the Southern Pacific Company. The Company has been experimenting with electric headlights for some time, and at last has perfected a light that can be operated by a dynamo on the engine which will illuminate the track for a distance of 2,000ft. Oil lamps light the track for only 200ft. ahead of the locomotive, and when running at a high speed engineers are frequently unable to stop, after observing an obstruction on the track, in time to prevent an accident. The Southern Pacific will be the first railroad company in the United States to equip all of its passenger train locomotives with electric headlights.

LIST OF THE ELECTRICAL PAPERS READ AT THE BRITISH ASSOCIATION.

The following is a complete list of the electrical Papers read and reports presented at the Ipswich Meeting of the British Association:—

SECTION A.

Sir Douglas Galton, F.R.S.—"Memorandum on the Reichsanstalt, Charlottenburg."
W. H. Everett.—"On the Field of a Solenoid."
E. S. Bruce.—"On Probable Projective Lightning Flashes."
Prof. Schuster, F.R.S.—"Some Observations with Lord Kelvin's Portable Electrometer."
Prof. Michie Smith.—"On Indian Thunderstorms."
W. H. Wood.—"On the Local Origin of the Aurora Borealis."
Prof. S. P. Thompson, F.R.S.—"On the Choice of Magnetic Units."
J. M. Barr, W. B. Burnie and Charles Rodgers.—"On Some New Methods and Apparatus for the Delineation of Alternate-Current Wave Forms."
Prof. W. E. Ayrton, F.R.S., and T. Mather.—"On Alternating Wave Tracers."
Lord Kelvin, P.R.S., Messrs. Maclean and Galt.—"Electrification and Diselectrification of Gases."
Prof. Rucker, F.R.S.—"As to whether Vertical (earth-air) Electrical Currents exist in the United Kingdom.'
Mrs. Ayrton.—"On the Equation connecting the P.D., Current, and Length of the Electric Arc."

SIR DOUGLAS GALTON'S PRESIDENTIAL ADDRESS TO THE BRITISH ASSOCIATION AT IPSWICH.

[ABSTRACT.]

In 1831, in the absence of railways, communication between different parts of the country was slow and difficult. Science was therefore localised. Under these social conditions the British Association was founded in September, 1831. The objects of the founders of the British Association were enunciated in their earliest rules to be: "To give a stronger impulse and a more systematic direction to scientific inquiry; to promote the intercourse of those who cultivate science in different parts of the British Empire with one another, and with foreign philosophers; to obtain a more general attention to the objects of science, and a removal of any disadvantages of a public kind which impede its progress." At its third meeting [Cambridge, 1833], the Association, through the influence it had already acquired, induced the Government to grant a sum of £500 for the reduction of the astronomical observations of Baily. And at the same meeting the General Committee commenced to appropriate to scientific research the surplus from the subscriptions of its members. I have always wondered at the foresight of the framers of the constitution of the British Association, the most remarkable feature of which is the lightness of the tie which holds it together. It is not bound by any complex central organisation. It consists of a federation of sections, whose youth and energy are yearly renewed by a succession of presidents and vice-presidents, whilst in each section some continuity of action is secured by the less movable secretaries. The governing body is the General Committee, the members of which are selected for their scientific work; but their controlling power is tempered by the law that all changes of rules or of constitution should be submitted to, and receive the approval of, the Committee of Recommendations. This Committee may be described as an ideal Second Chamber. It consists of the most experienced members of the Association.

The administration of the Association in the interval between annual meetings is carried on by the Council, an executive body whose duty it is to complete the work of the annual meeting. I believe that one of the secrets of the long-continued success and vitality of the British Association lies in this purely democratic constitution, combined with the compulsory careful consideration which must be given to suggested organic changes.

[After a glance at the condition of science in 1831, when the British Association was formed, and a reference to the good done by the Association in the matter of scientific standards, the President gave a sketch of the progress made since 1831 in geology, geography, and astronomy. Coming to physics, he said:] If we turn to the sciences which are included under physics, the progress has been equally marked. In optical science, in 1831 the theory of emission as contrasted with the undulatory theory of light was still under discussion. Young, who was the first to explain the phenomena due to the interference of the rays of light as a consequence of the theory of waves, and Fresnel, who showed the intensity of light for any relative position of the interference waves, both had only recently passed away. The investigations into the laws which regulate the conduction and radiation of heat, together with the doctrine of latent and of specific heat, and the relations of vapour to air, had all tended to the conception of a material heat, or caloric, communicated by an actual flow and emission. It was not till 1834 that improved thermometrical appliances had enabled Forbes and Melloni to establish the polarisation of heat, and thus to lay the foundation of an undulatory theory for heat similar to that which was in progress of acceptation for light. Whewell's report, in 1832, on magnetism and electricity shows that these branches of science were looked upon as cognate, and that the theory of two opposite electric fluids was generally accepted. In magnetism, the investigations of Hansteen, Gauss and Weber in Europe, and the observations made under the Imperial Academy of Russia over the vast extent of that empire, had established the existence of magnetic poles, and had shown that magnetic disturbances were simultaneous at all the stations of observation. At their third meeting the Association urged the Government to establish magnetic and meteorological observatories in Great Britain and her colonies and dependencies in different parts of the earth, furnished with proper instruments, constructed on uniform principles, and with provisions for continued observations at those places. In 1839 the British Association had a large share in inducing the Government to initiate the valuable series of experiments for determining the intensity, the declination, the dip, and the periodical variations of the magnetic needle which were carried on for several years, at numerous selected stations over the surface of the globe, under the directions of Sabine and Lefroy. In England systematic and regular observations are still made at Greenwich, Kew, and Stonyhurst. For some years past similar observations by both absolute and self-recording instruments have also been made at Falmouth—close to the home of Robert Were Fox, whose name is inseparably connected with the early history of terrestrial magnetism in this country—but under such great financial difficulties that the continuance of the work is seriously jeopardised. It is to be hoped that means may be forthcoming to carry it on. Cornishmen, indeed, could found no more fitting memorial of their distinguished countryman, John Couch Adams, than by suitably endowing the magnetic observatory in which he took so lively an interest. Far more extended observation will be needed before we can hope to have an established theory as to the magnetism of the earth.

In electricity, in 1831, just at the time when the British Association was founded, Faraday's splendid researches in electricity and magnetism at the Royal Institution had begun with his discovery of magneto-electric induction, his investigation of the laws of electro-chemical decomposition, and of the mode of electrolytical action. But the practical application of our electrical knowledge was then limited to the use of lightning conductors for buildings and ships. Indeed, it may be said that the applications of electricity to the use of man have grown up side by side with the British

Digitized by Google

Association. One of the first practical applications of Faraday's discoveries was in the deposition of metals and electro-plating, which has developed into a large branch of national industry; and the dissociating effect of the electric arc, for the reduction of ores, and in other processes, is daily obtaining a wider extension.

But probably the application of electricity which is tending to produce the greatest change in our mental, and every material condition, is the electric telegraph and its sister, the telephone. By their agency not only do we learn, almost at the time of their occurrence, the events which are happening in distant parts of the world, but they are establishing a community of thought and feeling between all the nations of the world which is influencing their attitude towards each other, and, we may hope, may tend to weld them more and more into one family.

The electric telegraph was introduced experimentally in Germany in 1833, two years after the formation of the Association. It was made a commercial success by Cooke and Wheatstone in England, whose first attempts at telegraphy were made on the line from Euston to Camden Town in 1837, and on the line from Paddington to West Drayton in 1838. The submarine telegraph to America, conceived in 1856, became a practical reality in 1861 through the commercial energy of Cyrus Field and Pender, aided by the mechanical skill of Latimer Clark, Gooch and others, and the scientific genius of Lord Kelvin. The knowledge of electricity gained by means of its application to the telegraph largely assisted the extension of its utility in other directions.

In 1843 Joule described his experiments for determining the mechanical equivalent of heat. But it was not until the meeting at Oxford, in 1847, that he fully developed the law of the conservation of energy, which, in conjunction with Newton's law of the conservation of momentum, and Dalton's law of the conservation of chemical elements, constitutes a complete mechanical foundation for physical science.

Who at the foundation of the Association, would have believed some far-seeing philosopher if he had foretold that the spectroscope would analyse the constituents of the sun and measure the motions of the stars; that we should liquefy air and utilise temperatures approaching to the absolute zero for experimental research; that, like the magician in the "Arabian Nights," we should annihilate distance by means of the electric telegraph and the telephone; that we should illuminate our largest buildings instantaneously, with the clearness of day, by means of the electric current; that by the electric transmission of power we should be able to utilise the Falls of Niagara to work factories at distant places; that we should extract metals from the crust of the earth by the same electrical agency to which, in some cases, their deposition has been attributed?

After dealing with engineering progress, the President concluded with a reference to the influence of the intercommunication afforded by the British Association on science progress.

The advances in engineering, he said, which have produced the steam-engine, the railway, the telegraph, as well as our engines of war, may be said to be the result of commercial enterprise rendered possible only by the advances which have taken place in the several branches of science since 1831. Having regard to the intimate relations which the several sciences bear to each other, it is abundantly clear that much of this progress could not have taken place in the past, nor could further progress take place in the future without intercommunication between the students of different branches of science. I claim for the British Association that it has fulfilled the objects of its founders, that it has had a large share in promoting intercommunication and combination. Our meetings have been successful because they have maintained the true principles of scientific investigation. We have been able to secure the continued presence and concurrence of the master-spirits of science. They have been willing to sacrifice their leisure, and to promote the welfare of the Association, because the meetings have afforded them the means of advancing the sciences to which they are attached. The Association has, moreover, justified the views of its founders in promoting intercourse between the pursuers of science, both at home and abroad, in a manner which is afforded by no other agency. The weekly and sessional reunions of the Royal Society, and the annual *soirées* of other scientific societies, promote this intercourse to some extent, but the British Association presents to the young student during its week of meetings easy and continuous social opportunities for making the acquaintance of leaders in science, and thereby obtaining their directing influence. It thus encourages, in the first place, opportunities of combination; but, what is equally important, it gives at the same time material assistance to the investigators whom it thus brings together. The reports on the state of science at the present time, as they appear in the last volume of our *Proceedings*, occupy the same important position, as records of science progress, as that occupied by those reports in our earlier years. We exhibit no symptom of decay.

Great Britain maintained for a long time a leading position among the nations of the world by virtue of the excellence and accuracy of its workmanship, the result of individual energy; but the progress of mechanical science has made accuracy of workmanship the common property of all nations of the world. Our records show that hitherto, in its efforts to maintain its position by the application of science and the prosecution of research, England has made marvellous advances by means of voluntary effort, illustrated by the splendid munificence of such men as Gassiot, Joseph Whitworth, James Mason, and Ludwig Mond; and, whilst the increasing field of scientific research compels us occasionally to seek for Government assistance, it would be unfortunate if by any change voluntary effort were fettered by State control. The following are the principal voluntary agencies which help forward scientific research in this country: The Donation Fund of the Royal Society, derived from its surplus income. The British Association has contributed £60,000 to aid research since its formation. The Royal Institution, founded in the last century, by Count Romford, for the promotion of research, has assisted the investigations of Davy, of Young, of Faraday, of Franklin, of Tyndall, of Dewar, and of Rayleigh. The City Companies assist scientific research and foster scientific education, both by direct contributions and through the City and Guilds Institute. The Commissioners of the Exhibition of 1851 devote £6,000 annually to science research scholarships, to enable students who have passed through a college curriculum, and have given evidence of capacity for original research to continue the prosecution of science, with a view to its advance, or to its application to the industries of the country. Several scientific societies, as, for instance, the Geographical Society and the Mechanical Engineers, have promoted direct research, each in their own branch of science, out of their surplus income; and every scientific society largely assists research by the publication, not only of its own proceedings, but often of the work going on abroad in the branch of science which it represents. The growing abundance of matter year by year increases the burden thus thrown on their finances, and the Treasury has recently granted to the Royal Society £1,000 a year to be spent in aid of the publication of scientific Papers not necessarily limited to those of that Society. The Universities and colleges distributed over the country, besides their function of teaching, are large promoters of research, and their voluntary exertions are aided in some cases by contributions from Parliament in alleviation of their expenses. Certain executive departments of the Government carry on research for their own purposes, which in that respect may be classed as voluntary. The Admiralty maintains the Greenwich Observatory, the Hydrographical Department, and various experimental services, and the War Office maintains its numerous scientific departments. The Treasury maintains a valuable chemical laboratory for Inland Revenue, Customs, and agricultural purposes. The Science and Art Department maintains the Royal College of Science, for the education of teachers and students from elementary schools. It allows the scientific apparatus in the national museum to be used for research purposes by the professors. The Solar Physics Committee, which has carried on numerous researches in solar physics, was appointed by and is responsible to this Department. The Department also administers the Sir Joseph Whitworth engineering research scholarships. Other scientific departments of the Government are aids to research, as, for instance, the Ordnance and the Geological Surveys, the Royal Mint, the Natural History Museum, Kew Gardens, and other lesser establishments in Scotland and Ireland; to which may be added, to some extent, the Standards Department of the Board of Trade, as well as municipal museums, which are gradually spreading over the country. For direct assistance to voluntary effort the Treasury contributes £4,000 a year to the Royal Society for the promotion of research, which is administered under a Board whose members represent all branches of science. The Treasury, moreover, contributes to marine biological observatories, and in recent years has defrayed the cost of various expeditions for biological and astronomical research, which in the case of the "Challenger" expedition involved very large sums of money. In addition to these direct aids to science, Parliament, under the Local Taxation Act, handed over to the County Councils a sum, which amounted in the year 1893 to £615,000, to be expended on technical education. In many country districts, so far as the advancement of real scientific technical progress in the nation is concerned, much of this money has been wasted for want of knowledge. And whilst it cannot be said that the Government or Parliament have been indifferent to the promotion of scientific education and research, it is a source of regret that the Government did not devote some small portion of this magnificent gift to affording an object lesson to County Councils in the application of science to technical instruction, which would have suggested the principles which would most usefully guide them in the expenditure of this public money. There could scarcely be a more advantageous addition to the assistance which Government now gives to science than for it to allot a substantial annual sum to the extension of the Kew Observatory, in order to develop it on the model of the Reichsanstalt.

The various agencies for scientific education have produced numerous students admirably qualified to pursue research, and at

Digitized by Google

the same time almost every field of industry presents openings for improvement through the development of scientific methods. If students do not easily find employment, it is chiefly attributable to a want of appreciation for science in the nation at large. This want of appreciation appears to arise from the fact that those who nearly half a century ago directed the movement of national education were trained in early life in the universities, in which the value of scientific methods was not at that time fully recognised. Hence our elementary, and even our secondary and great public schools, neglected for a long time to encourage the spirit of investigation which develops originality. This defect is diminishing daily. There is, however, a more intangible cause which may have had influence on the want of appreciation of science by the nation. The Government, which largely profits by science, aids it with money, but it has done very little to develop the national appreciation for science by recognising that its leaders are worthy of honours conferred by the State. Science is not fashionable, and science students—upon whose efforts our progress as a nation so largely depends—have not received the same measure of recognition which the State awards to services rendered by its own officials, by politicians, and by the Army and by the Navy, whose success in future wars will largely depend on the effective applications of science.

The Reports of the British Association afford a complete chronicle of the gradual growth of scientific knowledge since 1831. They show that the Association has fulfilled the objects of its founders in promoting and disseminating a knowledge of science throughout the nation. The growing connection between the sciences places our annual meeting in the position of an arena where representatives of the different sciences have the opportunity of criticising new discoveries and testing the value of fresh proposals, and the Presidential and Sectional addresses operate as an annual stock-taking of progress in the several branches of science represented in the sections. Every year the field of usefulness of the Association is widening.

PROF. W. M. HICKS' PRESIDENTIAL ADDRESS TO SECTION A.

[ABSTRACT.]

In making a choice of subject for my address the difficulty is not one of finding material, but of making selection. The field covered by this Section is a wide one. Investigation is active in every part of it, and is being rewarded with a continuous stream of new discoveries and with the growth of that co-ordination and correlation of facts which is the surest sign of real advancement in science. The ultimate aim of pure science is to be able to explain the most complicated phenomena of Nature as flowing by the fewest possible laws from the simplest fundamental data. A statement of a law is either a confession of ignorance or a mnemonic convenience. It is the latter, if it is deducible by logical reasoning from other laws. It is the former when it is only discovered as a fact to be a law. While, on the one hand, the end of scientific investigation is the discovery of laws, on the other, science will have reached its highest goal when it shall have reduced ultimate laws to one or two, the necessity of which lies outside the sphere of our cognition. These ultimate laws—in the domain of physical science at least—will be the dynamical laws of the relations of matter to number, space, and time. The ultimate data will be number, matter, space, and time themselves. When these relations shall be known, all physical phenomena will be a branch of pure mathematics. We shall have done away with the necessity of the conception of potential energy, even if it may still be convenient to retain it; and—if it should be found that all phenomena are manifestations of motion of one single continuous medium—the idea of force will be banished also, and the study of dynamics replaced by the study of the equation of continuity.

Before, however, this can be attained, we must have the working drawings of the details of the mechanism we have to deal with. These details lie outside the scope of our bodily senses; we cannot see, or feel, or hear them, and this, not because they are unseeable, but because our senses are too coarse-grained to transmit impressions of them to our mind. The ordinary methods of investigation here fail us; we must proceed by a special method, and make a bridge of communication between the mechanism and our senses by means of hypotheses. By our imagination, experience, intuition, we form theories; we deduce the consequences of these theories on phenomena which come within the range of our senses, and reject or modify and try again. It is a slow and laborious process. The wreckage of rejected theories is appalling; but a knowledge of what actually goes on behind what we can see or feel is surely if slowly being attained. It is the rejected theories which have been the necessary steps towards formulating others nearer the truth. It would be an extremely interesting study to consider the history of these discarded theories, to show the part they have taken in the evolution of truer conceptions, and to trace the persistence and modification of typical ideas from one stratum of theories to a later. I propose, however, to ask your attention for a short time to one of these special theories—or rather to two related theories—on the constitution of matter and of the ether. They are known as the vortex atom theory of matter and the vortex sponge theory of the ether. The former has been before the scientific world for a quarter of a century, since its first suggestion by Lord Kelvin in 1867, the second for about half that time. In what I have to say I wish to take the position, not of an advocate for or against, but simply as a prospector attempting to estimate what return is likely to be obtained by laying down plant to develop an unknown district. This is in fact the state of these two theories at present. Extremely little progress has been made in their mathematical development, and until this has been done more completely we cannot test them as to their powers of adequately explaining physical phenomena.

The theory of the rigid atom has been a very fruitful one, especially in explaining the properties of matter in the gaseous state; but it gives no explanation of the apparent forces which hold atoms together, and in many other respects it requires supplementing. The elastic solid ether explained much, but there are difficulties connected with it which decide against it. The mathematical rotational ether of MacCullagh is admirably adapted to meet these difficulties, but he could give no physical conception of its mechanism. Maxwell and Faraday proposed a special ether for electrical and magnetic actions. This ether requires the same mathematical treatment as that of MacCullagh. Lord Kelvin's gyrostatic model of an ether is also of the MacCullagh type. Lastly, we have Lord Kelvin's Labile ether, which again avoids the objections to the elastic solid ether. In MacCullagh's type of ether the energy of the medium when disturbed depends only on the twists produced in it. This ether has recently been mathematically discussed by Dr. Larmor, who has shown that it is adequate to explain all the various phenomena of light, electricity, and magnetism. Meanwhile, it may be borne in mind that the vortex sponge ether belongs to MacCullagh's type.

Already before a formal theory of a fluid ether had been attempted, Lord Kelvin * had proposed his theory of vortex atoms. The permanence of a vortex filament with its infinite flexibility, its fundamental simplicity with its potential capacity for complexity, struck the scientific imagination as the thing which was wanted. Unfortunately the mathematical difficulties connected with the discussion of these motions, especially the reactions of one on another, have retarded the full development of the theory.

Maxwell was, I believe, the first to point out the difficulty of explaining the masses of the elements on the vortex atom hypothesis. To me it has always appeared one of the greatest stumbling-blocks to the acceptance of the theory. We have always been accustomed to regard the ether as of extreme tenuity, as of a density extremely though not infinitely smaller than that of gross matter, and we carry in our minds that Lord Kelvin has given an inferior limit of about 10^{-19}. There are two directions in which to seek a solution. The first is to cut the knot by supposing that the atoms of gross matter are composed of filaments whose rotating cores are of much greater density than the ether itself. The second is to remember that Lord Kelvin's number was obtained on the supposition of elastic solid ether, and does not necessarily apply to the vortex sponge.

Ever since Prof. J. J. Thomson proved that a vortex atom theory of matter is competent to serve as a basis of a kinetic theory of gases, it has been urged by various persons as a fatal objection that the translation velocity of the atoms falls off as the temperature rises. I must confess this objection has never appealed to me. Why should not the velocity fall off? The velocity of gaseous molecules has never been directly observed, nor has it been experimentally proved that it increases with rise of temperature. We have no right to import ideas based on the kinetic theory of hard discrete atoms into the totally distinct theory of mobile atoms in continuity with the medium surrounding them. Doubtless the molecules of a gas effuse through a small orifice more quickly as the temperature rises, but it is natural to suppose that a vortex ring would do the same as its energy increases. To make the objection valid, it is necessary to show that a vortex ring passing through a small tube, comparable with its own diameter, would pass through more slowly the greater its energy. It is not, however, necessarily the case that in every vortex aggregate the velocity decreases as the energy increases. The mathematical treatment of thin vortex filaments is comparatively easy, and little attention has been paid to other cases. Let us attempt to trace the life history as to translation velocity and energy of a vortex ring. We start with the energy large; the ring now has a very large aperture, and has a very thin filament. As the energy decreases, the aperture becomes smaller, the filament thicker, and the velocity of translation

* "Vortex Atoms," *Proc.* Roy. Soc Edin., VI., 94; *Phil. Mag.* (4), 34.

Digitized by Google

greater. We can trace quantitatively the whole of this part of its history until the thickness of the ring has increased to about four times the diameter of the aperture, or perhaps a little further. Then the mathematical treatment employed fails us, or becomes very laborious to apply. Till 18 months ago this was the only portion of its history we could trace. Then Prof. M. J. M. Hill* published his beautiful discovery of the existence of a spherical vortex. This consists of a spherical mass of fluid in vortical motion and moving bodily through the surrounding fluid, precisely as if it were a rigid sphere.

If we pass on to consider how a vortex atom theory lends itself to the explanation of physical and chemical properties of matter independently of what may be called ether relations, we find that we owe almost all our knowledge on this point to the work of Prof. J. J. Thomson,† which obtained the Adams' Prize in 1882. This, however, is confined to the treatment of *thin* vortex rings, still leaving a wide field for future investigation in connection with thick rings and with vortex aggregates which produce no cyclosis in the surrounding medium. His work is an extremely suggestive one. He shows that such a theory is capable, not only of explaining the gaseous laws of a so-called perfect gas, but possibly also the slight deviations therefrom. Quite as striking is his explanation of chemical combination—an explanation which flows quite naturally from the theory. A vortex filament can be linked on itself: two or more can be linked together, like helices drawn on an anchor ring; or, lastly, several can be arranged together like parallel rings successively threading one another. In the latter case, for such an arrangement to be permanent, the strengths of each ring must be the same, and further, not more than six can thus be combined together. The linked vortices will be in permanent combination on account of their linkedness; the other arrangement may be permanent if subject to no external actions. If, however, they are disturbed by the presence of other vortices they may break up. When atoms are thus combined to form a compound, a certain number of molecules will always be dissociated; the compound will be permanent when the ratio of the average paired time to the unpaired time of any atom is large. Thomson considers every filament to be of the same strength. Then an atom consisting of two links will behave like a ring of twice the strength, one of three links, of three times the strength, and so on. On this theory chemical compounds are to be regarded as systems of rings, not linked into one another but close together, and all engaged in the operation of threading each other.

The energy of rings thus combined is less than when free; consequently they are stable, and the act of combination sets free energy. Further, Thomson points out that for two rings to combine their sizes must be about the same when they come into proximity; consequently combination can only occur between two limits of temperature corresponding to the energies within which the radii of both kinds of rings are near an equality.

Thomson's theory of chemical combination applies only to thin rings. Something analogous may hold also for thick rings, but it is clearly inapplicable to vortex aggregates similar to that of Hill's. We are not confined, however, to this particular kind of association of vortex atoms in a molecule. For instance, I have recently found‡ that one of Hill's vortices can swallow up another and retain it inside in relative equilibrium. The matter requires fuller discussion, but it seems to open up another mode of chemical combination.

A vortex atom theory of matter carries with it the necessity of a fluid ether. If such a fluid is to transmit transversal radiations, some kind of quasi-elasticity must be produced in it. This can be done by supposing it to possess energetic rotational motions whose mean velocity is zero, within a volume whose linear dimension is small compared with the wave length of light, but whose velocity of mean square is considerable. We can make little further progress until we know something of the arrangement of the small motions which confer the quasi-rigidity. This may be completely irregular and unsteady, or arranged in some definite order of steady motions. I am inclined to the view that the latter is nearer the truth. In this case we should expect a regular structure of small cells in which the motions are similar. By the word cell I do not mean a small vessel bounded by walls, but a portion of the fluid in which the motion is a complete system in itself. Such a theory might be called a cell theory of the ether. The simplest type perhaps is to suppose the medium spaced into rectangular boxes, in each of which the motion may be specified as follows. Holding the box with one set of faces horizontal the fluid streams up in the centre of the box, then turns round, flows down the sides and up the centre again. In fact, it behaves like a Hill's vortex squeezed from a spherical into a box form. Each box has thus rotational circulation complete in itself. The six adjoining compartments have their motion the same in kind but in the reverse direction, and so on. In this way we get continuous and energetic small motions throughout the medium, and the state is a stable one. If there is a shear, so that each cell becomes slightly rhomboidal, the rotational motions inside tend to prevent it, and thus propagate the disturbance, but the cells produce no effect on the general irrotational motion of the fluid, at least when the irrotational velocities are small compared with those of the propagation of light. In this case the rate at which the cells adjust themselves to an equilibrium position is far quicker than the rate at which this equilibrium distribution is disturbed by the gross motions. The linear dimensions of the cells must be small compared with the wave lengths of light. They must probably be small also compared with the atoms of gross matter, which are themselves small compared with the same standard. We may regard each cell as a dynamical system by itself, into which we pour or take away energy. This added energy will depend only on the shape into which the box is deformed.

At the Bath meeting of this Association, I sketched out a theory of the electrical action of a fluid ether in which electrical lines of force were vortex filaments combined with an equivalent number of hollow vortices of the same vortical strength.* An electric charge on a body depended on the number of ends of filaments abutting on it, the sign being determined by the direction of rotation of the filament looked at from the body. This theory gave a complete account of electrostatic actions, both quantitatively and qualitatively, and a more speculative one as to currents and magnetism. I could only succeed in proving at that time that if the filaments were distributed according to the same laws as electric lines of force, the distribution would be one of equilibrium. Larmor† has recently proved that this is also the necessary distribution for any type of a rotationally elastic ether, and consequently also for this particular case. Currents along a wire were supposed to consist of the ends of filaments running along it, with disappearance of the hollow companions, the filaments producing at the same time a circulation round the wire. A magnetic field was thus to be produced by a flow of the ether, but probably with the necessary accompaniment of rotational elements in it.

This latter, however, was clearly wrong, because each kind of filament would produce a circulation in opposite directions. The correct deduction would have been to lay stress on the fact that the field is due to the motion through the stationary ether of the vortex filaments, the field being perpendicular to the filament and to its direction of motion.

The fundamental postulate underlying this explanation of electric action is that when two different kinds of matter are brought into contact a distribution of vortex filaments in the neighbourhood takes place, so that a larger number stretch from one to the other than in the opposite direction—the distinction between positive and negative ends being that already indicated. To see how such a distribution may be caused, let us consider each vortex atom to be composed of a vortical mass of our secondary medium or cell-structure ether. The atom is much larger than a cell, and contains practically an infinite number of them. It is a dynamical system of these cells with equilibrium of energy throughout its volume. The second atom is a dynamical system with a different equilibrium of energy. Where they come into contact there will be a certain surface rearrangement, which will show itself as a surface distribution of energy in a similar manner to that which exists between a molar collection of one kind of molecules in contact with one of another, and which shows itself in the phenomenon which we call surface tension. In the present case the effect may take place at the interface of two atomic systems in actual contact, or be a difference effect between the two interfaces of the ether and each atom when the latter are sufficiently close. The surface effect we are now considering shows itself as contact electricity.

Such a distribution of small vortex filaments, stretching from one atom to another, will tend to hold them together. We therefore get an additional cause for aggregation of atoms. This does not exclude the others already referred to. They may all act concurrently, some producing one effect, some another—one combining, perhaps, unknown primitive atoms into elements, one elements into chemical compounds, and another producing the cohesion of matter into masses.

On this theory the difference between a conductor and a dielectric is that in a dielectric the ends of the filaments cannot pass from atom to atom, possibly because the latter never come into actual contact. In a conductor, however, we are to suppose that the atomic elements can do so. When a current is flowing, a filament and its equivalent hollow stretch between two neighbouring atoms, they are pulled into contact, or their motions bring them into contact, the hollow disappears, and the rotational filament joins its two ends and sails away as a small neutral vortex ring into the surrounding medium, or returns to its function as an ether cell. The atoms being free are now pulled back to perform a similar operation

for other filaments. The result is that the atoms are set into violent vibrations, causing the heating of the conductor. When, however, the metal is at absolute zero of temperature, there is no motion, the atoms are already in contact, and there is no resistance, as the observation of Dewar and Fleming tends to show. Further, as the resistance depends on the communication of motion from molecule to molecule, we should expect the electrical conductivity of a substance to march with its thermal conductivity. Again, on this theory the resistance clearly increases with increase of distance between atoms—*i.e.*, with increase of temperature. On the contrary, in electrolytic conduction the same junction of filament ends is brought about, not by oscillations of molecule to molecule, but by disruption of the molecule and passage of atom to atom. In this case conduction is easier the more easily a molecule is split up, and thus resistance decreases with increase of temperature. To explain the laws of electrolysis it is only necessary to assume that the strengths of all filaments are the same. A similar hypothesis, as we have seen, lies at the basis of J. J. Thomson's explanation of chemical combination, although it is not necessarily the case that we are dealing with the same kind of filaments. It is evident that the theory easily lends itself to his views as to the mechanism of the electric discharge through gases. The *modus operandi* of the production of the mechanical forcive on a conductor carrying a current in a magnetic field and of electrodynamic induction is not clear. Probably the full explanation is to be found in the stresses produced in the ether owing to the deformation of the cells by the passage of the filaments through them. The fluid moves according to the equation of continuity without slip, and subject to the surface conditions at the conductors. This motion, however, distorts the cells, and stresses are called into play. Any theory which can explain the mechanical forcives and also Ohm's law, must, on the principles of the conservation of energy, also explain the induction of currents.

The magnetic rotation of the plane of polarisation of light does not depend on the structure of the ether, or on the magnetic field itself, but is a result of the atomic configuration of the matter in the field modified by the magnetism. It is generally recognised as caused by something in the field rotating round the direction of the magnetic lines of force. Now the vortex atom, as usually pictured, is incapable of exhibiting this property. It is, however, an interesting fact, and one which I hope to demonstrate to this Section during the meeting, that a vortex ring can have two simultaneous and independent cyclic motions—one the ordinary one, and another which is capable of producing just the action on light which shows itself as a rotation of the plane of polarisation.

Instead of attempting to invent ethers, to deduce their properties from their specifications, and then seeing whether they fit in with experience, we may begin half way. We may assume different forms for the function, giving the energy of the medium when disturbed, apply general dynamical methods, and distinguish between those which are capable of explaining the phenomena we are investigating and those which are not. Invention is then called upon to devise a medium for which the desired energy-function is appropriate. This was the method applied by MacCullagh to the luminiferous ether. He obtained an algebraical form of the energy-function which completely satisfied the conditions for a luminiferous ether; its essential property being that the energy depended only on the rotational displacements of its small parts. He was unable, however, to picture a stable material medium which would possess this property. We recognise now that such a medium is possible if the rotational rigidity is produced by intrinsic motions in the small parts of the medium of a gyrostatic nature. In a most masterly manner Larmor * has recently investigated by general dynamical methods the possibility of explaining electric and magnetic phenomena by means of the same energy-function. Electric lines of force are rotational filaments in the ether,† similar in fact to those I suggested at Bath, whilst a magnetic field consists of a flow of the ether. The same difficulty in accounting for electro-dynamic induction arises, but the general form of the equations for the electrodynamic and magnetic fields are the same as those generally received.

Towards the end of this Paper he is led to postulate a theory of electrons whose convection through the ether constitutes an electric current. Two electrons rotating round each other are supposed to produce the same effect as a vortex ring. The mass of ordinary matter is attributed to the electric inertia of these electrons. The electron itself is a centre or nucleus of rotational strain. If I express a doubt as to the possibility of the existence of these nuclei as specified, I do so with great diffidence.* Whether they can or cannot exist, however, the general results of the investigation are not affected.

Since this Paper was published Larmor has read a second one on the same subject before the Royal Society, developing further his theory of the electron. The publication of this will be awaited with interest. It is impossible in an address such as this to go *seriatim* into the numerous points which he takes up and illuminates, because the mathematical treatment of the general question does not lend itself easily to oral exposition, even to an audience composed of professed mathematicians. There is no doubt but that this Paper has put the theory of a rotationally elastic ether—and with it that of a fluid vortex ether—on a sounder basis, and will lead to its discussion and elucidation by a wider circle of investigators.

* "A Dynamical Theory of the Electric and Luminiferous Medium," *Phil. Trans.*, 1894.

† The necessity that the filaments shall be in pairs does not seem to be recognised. This is, however, essential. Moreover, if the complementary circulations of the filaments between (say) a plate condenser be placed otherwhere than in the same region, the filaments between the plates must rotate as a whole; that is, an electric field would always be combined with a magnetic one.

* It would appear that the same results would flow if two particles oppositely electrified—*i.e.*, joined by two complementary filaments, as already described—were to rotate round each other.

STORAGE BATTERIES.†

BY H. A. EARLE.

When I undertook to read a Paper before this Association, I hoped that I might have been able to treat the subject in a more exhaustive manner; the time at my disposal has, however, been limited, and the subject is one of such magnitude, and the results under different conditions of test so numerous, that I have found it impossible to do more than give a general outline from a practical point of view. It is interesting to trace the history of storage battery manufacture, and, by so doing, each step in the advance up to the present time can best be considered.

The discovery of secondary currents dates back to 1801, when Gautherot found that silver or platinum wires, which had been used to decompose a saline solution, were capable of giving a reverse current of short duration. Ritter in 1803 was, however, the first to make a secondary battery, in which he employed plates of gold separated by cloth or paper, the same being moistened with a saline solution; he experimented with various metals, including lead, but the secondary currents obtained were of short duration, and the batteries only of scientific interest. It appears at first sight strange that Ritter when using lead obtained no increased effects, this being the metal exclusively employed at this time; he, however, used salt water, and this formed chloride of lead scarcely soluble, and a very bad conductor. On this account the current was very weak in comparison with that which would have been obtained if water acidulated with sulphuric acid had been used. Since that time many scientists have investigated the subject, and De la Rive in 1826 obtained secondary currents from platinum plates in a voltameter filled with water and sulphuric acid, and he closely approached the elements of our present storage battery, when, among his many experiments, he used in a primary battery a platinum plate covered with a film of peroxide of lead, and a zinc plate, immersed in an acid solution. The first powerful storage battery was introduced in 1860, when Planté constructed cells composed of lead plates immersed in an acid solution of 1·068 specific gravity (10 per cent. acid); these were a success, with the exception that the method employed for their formation—namely, frequent charges, discharges, reversals of charge, and periods of rest—was too long and expensive for practical purposes, several months being necessary to obtain a useful capacity. The subsequent rapid development and improvements in electrical machinery and lamps created a real demand for a good storage battery, and turned the thoughts of many to the subject, and the next and one of the most important of subsequent improvements was that introduced by Faure in 1881—namely, of pasting a coating of lead oxide on the surface of the plates, which rendered them, after a comparatively short formation, ready for use. The Faure cell was never, however, as originally designed, a practical success, for though the active material was encased in a covering of flannel or felt, the pasted coatings, being on upright surfaces and having insufficient adherence, came away within a period not sufficiently long to give economical results. Swan realised that the active material required a better mechanical support, and introduced a plate of grid form, the interstices serving to retain the material; this frame, combined with the Faure pasting, was the origin of the plate that has been largely used in this country and elsewhere. Up to the date of the expiration of the Swan and Faure patents, the manufacture of pasted plates in this country was in the hands of one company and its licensees, and competition was thereby to a great extent absent; this is, however, more likely to have been an advantage than otherwise, for much has meanwhile been done to perfect and cheapen the production of the solid lead plates, and these are making such strides forward that it seems probable they will eventually outstrip and replace their pasted rivals. Solid plates have

† Paper read before the British Association at Ipswich, Section G.

Digitized by Google

been made of various types, and some have been pasted to avoid the expense of formation, the paste in this case serving to give the required capacity till the action of charging and discharging gradually attacked the solid surface. Improved methods have, however, been discovered for effecting rapid formation at a reasonable cost, and, although pasting is now open to all, in all probability there will be little extension of its use—unless means are devised for the better retention of the material.

Another type which differs greatly from the solid lead plate, but which is not pasted, is the chloride plate. In this case the material to become active is a mixture of chloride of lead and chloride of zinc, which is cast into small tablets. These being framed by casting antimonious lead around them under high pressure the subsequent elimination of the chlorine and zinc leaves a porous structure of pure lead, of a crystalline nature, having good conductivity, and with a large surface exposed to the electrolyte, the result being a large capacity for a given weight and for the space occupied. The mere manufacture of an accumulator, with lead and sulphuric acid, is a simple matter, but when combined with the necessary requirements of low first cost for a given capacity and long life, it presents more difficulties than is perhaps generally supposed. Omitting the question of cost, the chief points to be considered are the *chemical action*, the *mechanical construction*, and the proper *treatment* of the cells when made. In lead batteries the minimum weight is limited by the chemical requirements: the theoretical value of lead peroxide is 4·44 grammes per ampere-hour, or roughly one pound is the equivalent of 100 ampere-hours; presuming that the positive and negative plates were identical, the value would be approximately 50 ampere-hours for one pound of peroxide and spongy lead. As a matter of fact the highest capacity plates yield only about seven ampere-hours per pound of positive and negative plates, or 16 ampere-hours per pound of peroxide and spongy lead, due to the facts that a conducting frame of considerable weight has to be employed, and to the impossibility in practical working of

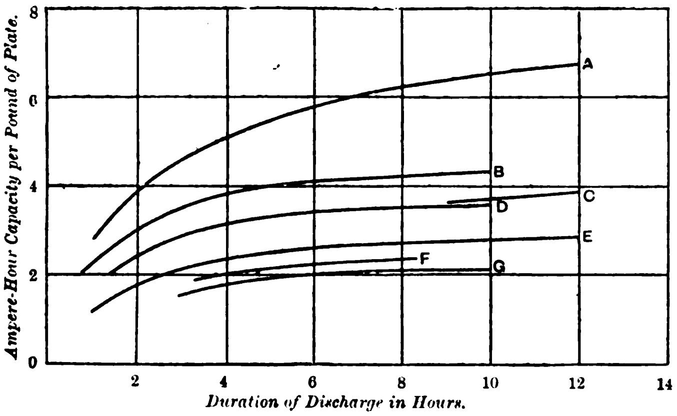

Fig. 1.

reducing the whole of the peroxide. To obtain the best results for a given weight, the frame must be reduced to a minimum consistent with the necessary strength and conductivity, and the distribution of the peroxide must be such as to admit of the perfect circulation of the electrolyte, and its penetration throughout the mass. When the active material is retained in holes or interstices due provision must be made for its expansion on oxidation, for the power exerted is so great that it will bend or burst a frame which holds it too tightly; various methods have been adopted to prevent buckling, but it is still a source of trouble with perforated pasted plates. Solid grooved or ribbed plates, however, the grooves on which are filled with paste, are not subject to the same extent to this fault. Solid plates on which the active material is formed out of the substance of the plate itself are practically free from it. In the chloride plate ample provision is made for this increase in volume by the elimination of the chlorine and zinc, which renders the structure porous and cellular.

Nothing is more interesting than the behaviour of cells under various conditions, and from the innumerable curves that can be plotted we can readily study the effects due to different rates of charge and discharge, to the penetration and strength of the electrolyte, and to the ratio of the positive and negative plates; from these and many other similar tests much useful information can be obtained for guidance both in manufacture and treatment. There is a given rate of charge for every type of cell which is most suitable, not only for its efficiency but also for its durability. With some types a high rate is quite inadmissible, and a period of ten hours is required. Other types, however, are of such a construction that they may be fully charged in four hours without detriment. This variation is mainly due to the disposition of the active material, to its thickness, and to the method of its production, namely, whether it has been mechanically applied, or electrolytically produced. Most of the effects of varying rates of charge can be ascertained from the resultant discharge, but discharge curves have nevertheless characteristics of their own which are to a great extent unconnected with the conditions of charge, and they depend upon the type of plate, strength of acid, the rate of discharge, and other influences.

A series of curves is shown in Fig. 1, and these give at a glance results obtained with plates of various manufacture; in every instance the weight of one positive and one negative has been taken. Knowledge of the ratio of weight of active material to frame is naturally necessary for the complete investigation of these curves, but in this case the weight of the plates themselves has only been taken into consideration, as it is merely intended to show results obtained from various types of plates at present manufactured.

Curve A is taken from plates, the active material on which is of a very porous and cellular nature, of $\frac{5}{16}$ths of an inch thick. It will be noticed that the capacity per pound of plate continues to rise up to the 12-hour rate, and at that point is still slightly on the increase. This increase is no doubt partly due to the gradual penetration of the acid, and partly to the rapid sulphation of the surface at the higher rates. Curve B is that given by a positive plate, the active material on which is distributed in a thin layer over a very large surface, the negatives being the same as employed for curve A. This plate gives less ampere-hours per pound of plate, owing to its possessing a heavy frame, but per pound of peroxide of lead its yield is greater; the active material in this plate is not formed out of the substance of the frame, but is entirely independent of it. A plate of this description, in which the whole face of the active material is directly exposed to the electrolyte, is capable of giving its maximum capacity at a comparatively high rate of discharge. A thin layer of peroxide spread over a large surface reduces the clogging of the surfaces to a minimum, and a free circulation of the electrolyte admits of fresh acid of the proper specific gravity being continually available. Curve C is obtained from a pasted plate suitable for slow rates of discharge, and from its rise in capacity at reduced rates we notice somewhat similar characteristics to that in curve A. There is, however, a remarkable point of difference between curves A and C, for the plates in each instance contain approximately 30 per cent. by weight of active material; curve A therefore gives us about double the ampere-hour yield per pound of active material over curve C, and this is obtained by the cellular and porous structure of the material in the A curve plate. Curve D is taken from plates cast with ribs on their surfaces, the active material being formed out of the substance of the plates themselves; the curve is very similar to B, but falls lower on the scale, this being caused by the weight of the positive plate, its thickness being considerable in order to give a reserve of metal, which in its turn is acted upon as the plate gradually disintegrates. Curve E is given by plates, the surfaces and interior being full of blow holes, which gives a large exposed area; their weight for a given output is, however, large. Curve F is a pasted plate with a solid frame, which gives a poor return for its weight; in this curve we notice the rise in capacity at reduced rates due to pasted plates. Curve G gives the capabilities of very heavy plates, which are pasted on their surfaces, the paste being intended merely to give the required capacity till its disintegration, by which time the frame itself has been sufficiently formed to do the work; the rapid flattening of this curve indicates that the layer of paste is thin.

The curve of voltage of a discharging cell varies greatly, and is dependent upon the rate of discharge, the strength of acid, the distance of plates apart, its curve of internal resistance, and the treatment it has been subjected to beforehand, besides many other interesting conditions. Fig. 2 demonstrates the effect of varying rates; these curves have all been obtained from cells of the same type, the acid having been approximately 1,210 specific gravity when the cell was fully charged. Discharges at varying rates are given—namely, 1 hour, $2\frac{1}{2}$, $3\frac{1}{2}$, $5\frac{1}{2}$ and $7\frac{1}{2}$ hours, and, though slightly different results would be obtained with other types of cells, they may be taken as fair approximation for general reference.

When considering the question of fall in volts on discharges at different rates, it will not be out of place to draw attention to conditions that are frequently given in specifications for storage batteries—in some instances a fall in volts not exceeding 8 per cent., 10 per cent., or 12 per cent. is allowed, and the rate in amperes, and the time in hours, for which the discharge is to be maintained, are stated. This is in most instances unsatisfactory, for what are we to take as our starting point? The E.M.F. on open circuit immediately after complete charge is practically a fixed value, with a given type of cell and a known strength of acid. But the fall in the first few minutes varies greatly according to the rates of discharge, and at high rates it may fall as much as 10 per cent. in a few minutes or even seconds, before a comparatively straight line has been reached, and the cell is working at its normal voltage for the specified rate of discharge. This is quite clear by reference to Fig. 2.

Another point to which our attention is drawn is the fall of voltage on open circuit after the completion of charge. A series of curves (Fig. 3) are exhibited, showing the fall in voltage for a period of 21 hours, each curve being for a different strength of acid ; it is therefore evident that if a given percentage of fall is allowed, it will be most advantageous for the manufacturer, but not for the purchaser, to allow the battery to stand for a few hours in order that this useless high voltage be reduced. The best way to meet this point is, however, to take the first reading of voltage five or ten minutes after the discharge has commenced.

In other specifications the voltage is fixed to a hundredth of a volt, and the cell must give the specified capacity above this limit in many instances, and especially when high discharge rates are specified the voltage given is much too high on the curve, and in some instances I have found it actually fall on a straight portion of the same, so that the time at which this point is passed raises an unpleasant difference of opinion between the buyer and the seller. This class of specification generally necessitates a very much larger battery than was intended, with corresponding increased cost, and should the manufacturer not have been exceedingly careful in preparing his estimate, he may find that the buyer is not satisfied with a good excess of ampere-hours, but will have his volts as well, even if this means 50 per cent. in ampere-hours in excess of what he thought he was ordering.

There are many ways in which a specification can be framed so that a battery of the exact size required is obtained, and there is no doubt that it is most satisfactory to all concerned if the exact capacity in ampere-hours is specified, and the final voltage of the complete battery at a given rate, the number of cells being omitted. Under these conditions, if the individual cells are discharged down to a low voltage, more cells would be required, but each additional cell on a 100-volt circuit adds 2 per cent. to their number, and correspondingly increases the cost of a battery composed of cells of a given size. On the other hand, a low voltage per cell on discharge enables—up to a given limit—the number of plates per cell to be reduced, and the cost of cell as well. In a competitive tender the manufacturer would, therefore, work out the cheapest arrangement, and I find that this would not admit of the individual cells being discharged to too low a voltage, and that the purchaser would obtain exactly what he required at the lowest price. The actual number of regulator cells is of small moment to the user, and the additional number required when the individual cells are discharged down to a voltage of 1·8 in place of, say, 1·9, is only two in a 100-volt battery.

When tests are made to check the efficiency and capacity of a battery, we can place no reliance on the figures obtained from a single charge or discharge. As a rule no two consecutive discharges from a cell are identical, even when the same is discharged with the same current and down to the same voltage, every discharge being greatly influenced by the previous treatment. The table given above clearly demonstrates this :—

This table is in no way intended to be a guide as to what can be obtained in efficiency tests, but is merely to show the irregular nature of results obtained with slight variations in time, and maximum voltage of charge; the rated capacity of the cell was 15 amperes for 10 hours, or 150 ampere-hours. Charge No. 1 we can omit, as this was given to complete the formation of the cell. Charge No. 2 was for a similar purpose. Charge No. 3 was continued, as were also charges 1 and 2 till the voltage had practically ceased to rise ; a high voltage on charge gives a good return in ampere-hours on the discharge, but if a cell is forced to its maximum capacity we obtain a poor return in efficiency. Charge and discharge No. 4 are very similar to No. 3. Charge No. 5 was stopped when the E.M.F. had risen to 2·5 volts and 30 per cent. less ampere-hours had passed through the cell. Studying the figures up to the end of charge 5, it would have been practically impossible to assume what was going to happen on discharge No. 5 ; on taking this discharge we obtain 20 per cent. increase both in ampere-hour and watt-hour efficiency, and the very high percentage of the former, namely 99·2 per cent., points to the fact that peroxide which had been previously inactive was reduced. The first five discharges you will note were all taken down to 1·70 volts ; this cell had never been used before, so we have its history up to the tenth discharge in the table. The strength of acid at end of charge was practically 1·300 specific in every instance. Charge No. 6 was only continued to 2·40 volts, but it required 2½ hours longer charge to reach this voltage than it previously did on charge 5 to reach 2·5 volts, and this was without doubt due to the good service rendered on the last discharge. The remaining charges and discharges show that the highest efficiencies are obtained when the cell is not charged up to a high voltage, and if worked within reasonable limits 90 per cent. in ampere-hours, and about 80 per cent. in watt-hours, can be obtained with the cell in question when in good order.

Usually, efficiency is not of great importance, for presuming a central-station battery to give one-tenth of the total supply, a variation of even 10 per cent. in efficiency would only represent 1 per cent. variation in the total output; but the time may come when batteries are so cheapened and perfected, that they supply the whole demand of our stations, and their efficiency will then be one of importance, and we may be confronted with specifications as strict as those now framed for dynamos.

The strength of acid solution to be used in a cell is an important point. In the first place, this greatly influences the voltage, as we have seen from Fig. 3; it has also a great effect upon the life ; besides this, in strong acid the plates sulphate more readily, and the sulphate is more difficult to reduce ; it is therefore necessary to carry out most careful tests to ascertain what strength of acid should be used in each type of cell.

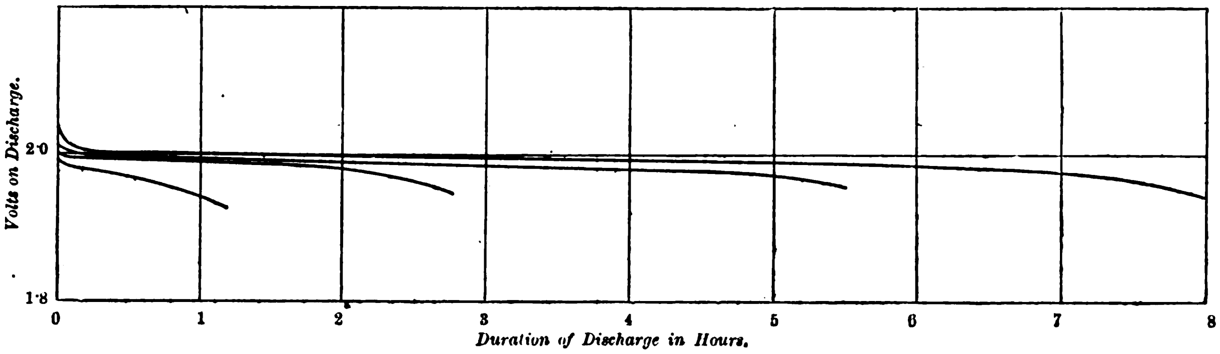

Fig. 2.

Digitized by Google

The resistance of acid solutions of different strengths is also a most important consideration, and on Fig. 4 four curves are shown giving its resistance at 0°, 8°, 16° and 24°C. Taking 16°C. as a mean working temperature, it will be noted that acid of about 1·250 specific gravity has the least resistance, and it might be assumed, therefore, that this was the best strength to work at; but we must bear in mind that this strength does not give us the highest voltage, and, moreover, the gravity gradually falls as the cell discharges, and when working with this strength we have falling voltage on discharge, and at the same time increasing resistance of the electrolyte; no fixed law can be laid down, as each type of cell requires a given strength for best results.

Immediately upon commencing our research with a view to ascertain the proper strength of acid, we find that we are confronted with another problem of great interest, which is that different

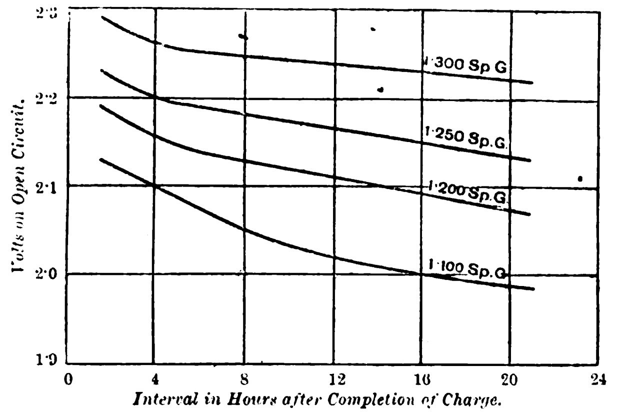

Fig. 3.

strengths give us different capacities from our cell. Fig. 5 gives two most interesting and instructive curves taken from two cells of the chloride type—one with positive and negative plates of 0·24 of an inch thick (curve A), and one with positive and negative plates of 0·4 of an inch thick (curve B). Each cell was discharged at a rate equal to 0·45 of an ampere per lb. of plate. The rate per pound of active material is nearly the same for each cell, though perhaps slightly higher for the thinner plates. The rate of discharge per superficial area was therefore approximately 40 per cent. greater with the thick plates than with the thin. The curves give the yield in ampere-hours per pound of active material with different strengths of acid. Considering the thin plate curve first, we find that with acid of 1·070 we do not obtain more than about 3 per cent. of the maximum capacity; from this point to 1·230, at which point we obtain the maximum capacity, it rises very rapidly;

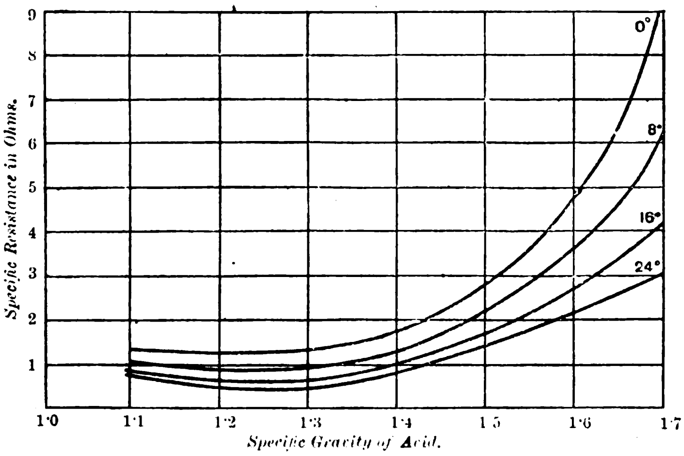

Fig. 4.

each addition of 1 per cent. to the sulphuric acid present in the electrolyte giving an increase of about one ampere-hour capacity per pound of peroxide. From 1·230 to 1·500 it falls as rapidly almost as it rose, and at the latter figure we obtain only 16 per cent. of the maximum. Taking the thick plate curve: at 1·040 specific gravity we obtain about 6 per cent. of the maximum capacity, and it rises till 1·270 is reached; it then falls rapidly, and at 1·500 the output is practically *nil*. Considering these two curves we note that the thin plates give as a maximum 15 ampere-hours per pound of peroxide and spongy lead, or 30 ampere-hours per pound of peroxide alone, or about one-third of the theoretical value. The thick plates, on the other hand, give 10 ampere-hours per pound of peroxide and spongy lead, or 20 ampere-hours per pound of peroxide alone, or about one-fifth of the theoretical value.

The natural question is, Why is this the case; also why are the thick plates the best with very weak acid, and why do they give such a much poorer return with acid of the strength usually employed? I consider that, up to the point at which the curves cross, the better result obtained from the thick plates is due to the fact that on completion of the charge in weak acid the active material is saturated with strong acid, and the quantity contained in the same would be greater with the thick plates than with the thin, and they would therefore give a better output with weak acid than the thin plates. Their increased thickness, however, is of no advantage with acid of the ordinary strength, when the capacity is chiefly dependent upon the penetration of the acid. If we study the portion of the thick-plate curve between 1·150 and 1·400 specific gravity, and compare it with the thin-plate curve, we find that the capacity is practically reduced inversely as the thickness or weight of the plate, and the rate of discharge per superficial area. Quite apart from the question of the proper thickness of the active material, we can see at a glance that very different capacities are obtained with different strengths of acid. On the top of the same figure the mean volts during the discharge are given; these, it will be seen, rise steadily as the strength of the acid is increased. A striking feature is that the curves of voltage cross at the same point that the curves of capacity cross. Upon consideration we come to the conclusion that this is what would be expected, as the rate in amperes on discharge was the same in every case, and an increase in ampere-hours per pound of material means a longer time to complete the discharge, and we see from Fig. 2 that the greater the length of the discharge the higher the mean voltage.

It is the manufacturer's business to make as good a cell as possible, but when it leaves his hands it is judged by the service it renders during its life, and this depends to a very great extent upon

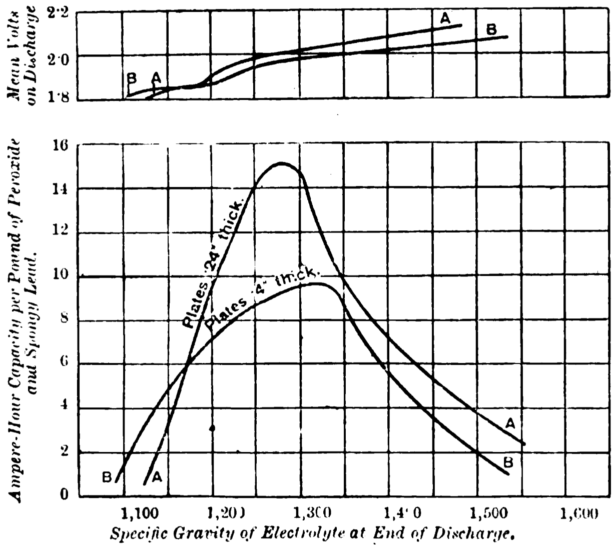

Fig. 5.

the treatment it receives. In the first instance, purity of the electrolyte is essential; brimstone acid should be used, as this is the least likely to contain foreign substances. If this is diluted on the spot the water must be pure, preferably rain, or, if possible, condensed water. With regard to the first charge of the battery, it is generally imperatively stated that this must commence immediately upon the acid being put into the cells; this is, no doubt, necessary with imperfectly-formed pasted plates, or with plates which have been for some time exposed to the air, as they would readily sulphate and require a considerable time to reduce. But positive plates which have been fully formed, and negatives in good condition, are very slightly affected.

Fig. 6 gives five curves, which I have prepared in order to show results obtained from plates in different conditions, some having been left standing in the acid while others were charged. Curve A shows the specific gravity of the acid in the cell in which the plates were allowed to stand for 22½ hours without being charged. During this period it remained absolutely constant—sulphation was therefore absent; the charge was then commenced and continued for eight hours—a rise in specific gravity took place, raising the electrolyte to a gravity above that at which it was put into the cell, which showed that sulphate was previously present in the plates. Curve B shows what happened in another identical cell. Directly the charging current was started the gravity fell rapidly. This I presume is due to the formation of oxide of lead from the pure lead remaining in the active material, and this is sulphated before becoming peroxide of lead. The current throughout the charge was kept constant, and from the curve we see that practically the same number of ampere-hours were expended during the fall as

Digitized by Google

during the rise; the specific gravity in this instance also rose slightly above its initial value. The plates in Curve C, which had been standing, sulphated slightly, and reproduced on being charged to a small extent a similar curve to B, and the plates (Curve D) which were charged at once give a very small fall but a considerable rise, showing that sulphate was present in the plates. Curve E is for plates which stood before being charged, and in this instance we notice that no sulphation took place, and that they gave a small fall and rise. My chief object in giving these curves is to demonstrate how very slight differences can give considerable variations.

To return again to the treatment of cells, the chief causes of destruction are too prolonged or excessive rates of discharge, insufficient charging, overcharging, long periods of rest on open circuit without charging, and allowing cells to remain after complete discharge for many hours before recharging. There is also another point which is worth mentioning. Frequently, through under charge or over discharge, the plates become heavily sulphated, the cells no longer give their proper output, and the specific gravity of the electrolyte falls considerably. Of course, a prolonged charge will put this right, but frequently it is assumed that, as the specific gravity is low, the acid merely requires strengthening, and this is done with the best intentions; the fault is, however, aggravated and the plates sulphate more heavily than before. I found on one occasion that acid had been periodically added, and the specific gravity rigidly maintained at 1·200, the charge being always stopped when this strength was reached. The cells were naturally working badly; a prolonged charge was accordingly given, and this raised the strength of the electrolyte as high as 1·450 in some cells, which was a clear indication of what had been done. We find, therefore, that a multitude of causes influence the working and life of storage batteries, and that many of these can be varied at will; the problem, therefore, is to so combine all useful effects that we produce the best possible article with due consideration to low cost. It would be a natural question to ask, What do you consider the best possible article?—and this is easily answered. In a secondary battery we have lead, sulphuric acid solution, and the resultant compounds, and nothing else. The ideal cell is one that is indestructible, and this being given, the first cost and weight, if kept within reasonable limits, are of little moment. At the present moment the life of a cell is its value, and all types are constructed with the knowledge of certain death, and in most types this lingering death is provided for, for we find at the bottom of the boxes a sufficient space to act as a receptacle for the deposit from the disintegrating plates; in other types, where the active material is held permanently in position, disintegration still goes on, with consequent loss of contact. Now this disintegration is what we have to stop; the deposited disintegrated material is as good as ever, for nothing is wasted, and provided it were held in perpetual firm and good electrical contact with the frame, in such a manner that the free circulation and penetration of the acid were not hindered, and the internal resistance were not unduly increased, we should have produced an ideal and indestructible cell.

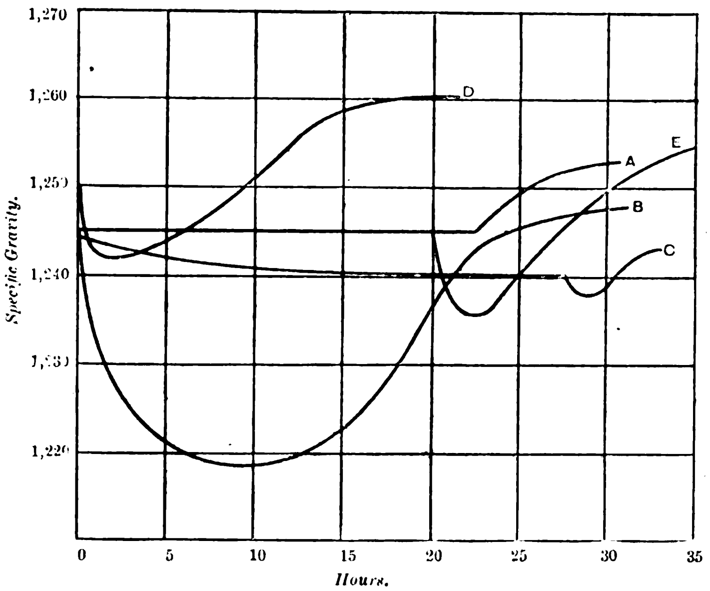

FIG. 6.

I have brought to your notice only a very few of the many interesting features in connection with secondary batteries, and these only in a most superficial manner. I have, however, endeavoured to give a general outline of results obtained in practice, and have not entered into a discussion upon other more serious questions. Many conjectures arise in one's mind when considering the causes of different effects, and each point requires much time and study in order that a fixed law may be deduced from the results obtained, and, again, the results of tests are often so conflicting, and depend so much upon very small differences of condition, that it is by no means an easy matter to arrive at the truth.

SOME LESSONS IN TELEPHONY.*

BY A. R. BENNETT, M.I.E.E.

In 1845 Mr. J. C. Bourne, in his history of the Great Western Railway, wrote: "It is a well-established truth in the history of trade and commerce that the traffic between two cities or countries will increase in proportion to the facilities of communication afforded, or to the speed, security, and cheapness with which such communication can be effected." The truth of this proposition had been demonstrated before Bourne's time in respect to common roads and waterways; since experience has shown that no town can prosper unless it be connected with the railway system of the country. In the beginning, several towns, by spending large sums in opposing railway Bills, succeeded in keeping off the main lines of communication, but the magnitude of the error has long since been manifest, and great efforts have been made, not always successfully, to repair it. Bourne's axiom may nowadays be admitted to embrace telegraphic and telephonic facilities, for places wanting these are at a great disadvantage as compared with more fortunate neighbours. If commerce may be held to constitute the life-blood of a modern nation, roads, railways, and waterways are the arteries through which this blood is conducted, while telegraphs and telephones may be compared to the nerves which feel out and determine the course of that circulation which is a condition of national prosperity. Given two nations, equal or nearly so in natural resources and in the talents and industry of their inhabitants, that one will succeed the better in commerce which possesses the most extended and cheapest facilities for transport the general intercommunication. It has recently been demonstrated that the United Kingdom is deficient in at least two of these essentials—railways in their branch or feeder form, and telephones, which are the natural feeders of the telegraphs. Why this is so may best be discovered by ascertaining by what means, technical or economical, those nations which have most conspicuously outstripped us have attained their superiority. For the purposes of this Paper, in which is considered the telephonic branch of the question, the countries of Europe have been divided into three groups: (1) well telephoned; (2) indifferently telephoned; (3) badly telephoned.

A country may most properly be said to be well telephoned when its smaller towns and villages enjoy facilities, for the existence of a few large exchanges in the capital and chief towns does not entitle it to that distinction. For instance, France, Russia and Portugal all possess good exchanges in their capitals, but are nevertheless badly telephoned as a whole, since their smaller towns and villages are excluded from the circle. On the other hand, we find that the Grand Duchy of Finland, under the same crown as Russia, but enjoying a different system of administration, is distinctly well telephoned. Its area exceeds that of the United Kingdom, although the greater part of its surface consists of lake, forest and waste; its staple industries are fishing and agriculture, yet a telephonic map of Finland discloses a veritable network of lines. All the towns and many of the villages possess exchanges, while the capital, Helsingfors (population 65,000), is one of the best telephoned cities in the world. Last year there were 198 exchanges in Finland, or one to each 12,626 inhabitants. In the United Kingdom there were but 578 exchanges, or one to each 65,537 inhabitants. In proportion to its population, Finland had therefore more than five times as many centres of telephonic activity as the United Kingdom. Even the people of the Aland Islands, in the middle of the Baltic, find a telephone exchange so well worth paying for at the rates which are found remunerative by the exploiting company that in Mariehamn, the capital, there is an exchange telephone to every 13 inhabitants. In fact, Mariehamn is entitled to the distinction of being the best telephoned town in the world. Another Finnish town, Viborg (population 22,344), has an exchange telephone to every 33 inhabitants, and other towns have one to 36, 37, 39 and 40.

Norway is, however, the best telephoned country on the whole. It has a population of 2,000,000, and has little to rely upon in the world's struggle but agriculture, forestry and fishing. Seventy per cent. of its total area is uncultivable, and another 24 per cent. is forest. It has but half-a-dozen towns, the bulk of the population residing in widely-scattered villages. Yet it possesses no fewer than 256 telephone exchanges, or one exchange to each 7,812 inhabitants—more than 8½ times the number in the United Kingdom in proportion to population.

* Paper read before the British Association at Ipswich, Section G.

Digitized by Google

Sweden, which takes the second place in the list of well-telephoned countries, possesses greater resources than Norway. It has a population of not quite 5,000,000, one-half of which is dependent on agriculture. Eighty per cent. of the people live outside the towns. A radius of 43½ miles round Stockholm, equal to 5,945 square miles, is unquestionably the best-telephoned bit of country in the world. Almost every village possesses two competing telephone exchanges, while rival systems of trunk lines place the whole of this large area in practically instantaneous communication.

Denmark, with its population of 2,250,000, and its staple industries of agriculture and dairy farming, takes an honourable place, having 152 telephone exchanges within its borders, or one to every 14,639 inhabitants.

The four foregoing countries form a class by themselves. Their telephonic development has been due almost exclusively to companies and co-operative societies. In Sweden the State has of recent years assumed an important position in respect to telephony, but its proceedings and tariffs have been based upon the previously-established procedure and tariffs of the companies whose systems it found in operation. In the two next instances the development attained is due wholly to the fostering care of the respective States.

Switzerland has a population of 3,000,000, which is served by 155 telephone exchanges, or one to every 19,355 inhabitants. All its towns and many of its villages possess telephone stations, and are connected by trunk lines. The Grand Duchy of Luxemburg contains 998 square miles, which is also precisely the area of Dorsetshire. The respective populations are 211,088 and 194,517. Agriculture is the staple industry of Luxemburg, as it is of Dorset.

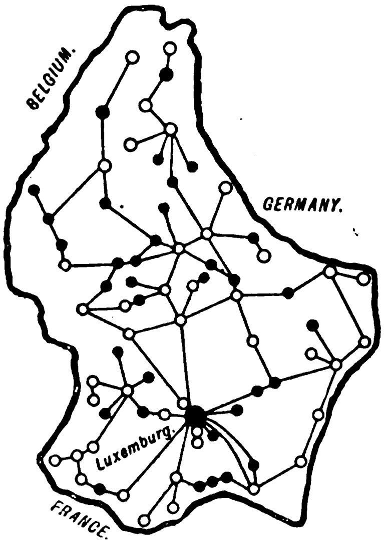

Fig. 1.—Telephonic Map of the Grand Duchy of Luxemburg. Area, 998 sq. miles. Population, 211,088.

We find, however, that while Luxemburg possesses 59 telephone switch rooms within its borders, or one to each 3,577 inhabitants, Dorset has only three—Dorchester, Weymouth, and Poole—or one to each 64,839. Luxemburg had last year 1,315 exchange lines; Dorset, at the present moment, possesses about 70. In Luxemburg there is an exchange telephone to every 160 souls; in Dorset, one to 2,778. Every town and village of Luxemburg is in telephonic communication with the capital and with each other. The accompanying maps (Figs. 1 and 2) exhibit the different stages of development attained in these two equal areas. And yet many counties are worse off than Dorsetshire is.

This completes the list of the European countries which are well telephoned, and constitute Group I. The least favourable result in this group is 328 persons per exchange telephone. A considerable jump must be made in order to reach the best country of Group II. This is the Imperial German Post Office territory, which comprises the whole of the German empire except Bavaria and Wurtemberg. Within its limits there was last year one telephone to every 449 inhabitants. It is noteworthy to remark that the comparatively good position taken by Germany is due to the fact that Berlin, Hamburg, Frankfort-on-Maine, and other chief towns possess very large exchanges, Berlin and Hamburg being amongst the largest in the world, even Hamburg (population 622,530) having a larger number of subscribers than London (population 5,600,000). But the small towns and villages are not developed, and rural intercourse by telephone is practically non-existent. The reason is that the German Post Office has a uniform tariff, applicable equally to the capital and to the smallest village, which, although reasonable for Berlin, is prohibitive for the country folk. The results obtained in Bavaria and Wurtemberg are not dissimilar. Wurtemberg has a lower initial tariff than the Imperial Post Office, but is hampered with restrictions which operate against rural development.

The United Kingdom comes next in order of merit, with one exchange telephone to every 636 persons. These figures, like the Continental ones, refer to last year. The ratio has improved since then both at home and abroad, but the relative positions remain unchanged.

Holland and Belgium complete Group II. A wide gap intervenes between this and Group III., or badly-telephoned class. The best country of this is France, with one exchange telephone to every 1,432 persons; and the worst is Russia, which can only show one to each 13,102 inhabitants.

The foregoing facts are presented in the table, which also gives the leading characteristics of the management in each country.

The questions naturally arise, "To what causes are such vast differences in development to be ascribed?" and "Why is the United Kingdom, with its preponderating commercial importance and unparalleled spirit of enterprise, only tenth on the list, instead of first?" A study of the table supplies the answer. It shows that telephonic development is proportional to the prevalence of the following features: (1) Low rates; (2) local management; (3) facilities for rural intercourse; (4) competition. At least three of these are characteristic of each of the six countries which compose Group I. On the other hand, they are almost completely absent from Groups II. and III., the leading characteristics of which are (1) high rates, (2) centralised management, (3) neglect of small towns and rural districts, (4) absence of competition.

The operation of low rates and competition in the direction of development is easily understood, but that of local management is not so obvious. Its importance, however, is great. No two places are precisely alike in commercial, social or topographical features, and telephonic arrangements which suit one neighbourhood admirably are not appreciated in another where other conditions call for other plans. To meet the wants of a locality fully, it is necessary that its character should be thoroughly understood at the headquarters of management, and this, when exchanges are numerous, is not attainable. On the other hand, a Board or council of local men know the requirements of the community exactly; hence the superiority of the results presented by the Scandinavian local companies and co-operative societies. Wherever management is centralised, uniformity is aimed at as a means to economy and of saving trouble, and what appears good in the capital is apt to be imposed on every other town.

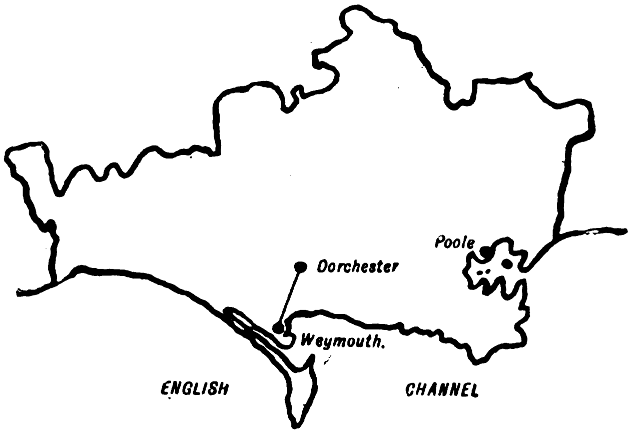

Fig. 2.—Telephonic Map of the County of Dorset. Area, 998 sq. miles. Population, 194,517.

In the countries of Group I. special attention is given to small town and rural development. In Switzerland a village council, commune, or other local authority may establish and manage a telephone station in one of its own buildings, and work it with its own employés, simply paying to the State the ordinary subscription of £4. 16s. for the first, £4 for the second, and £3. 4s. for the third and subsequent years, for the privilege of a junction with the general telephone system of the country. Such stations, of which there are 129 in Switzerland, are available for the despatch and receipt of written telegrams as well as of telephone messages. The local authority is authorised to collect a small surcharge on the ordinary tariff to cover expenses incurred for wages, office, and the annual payment to the State. In Luxemburg a similar system prevails, and is taken advantage of by 34 local authorities. The annual payment to the State for the connection of the municipal station to the general system of the country is uniformly £4 per annum. France has adopted a similar system, but with a much higher scale of charges and with restrictions which appear irksome

Table.

Order of merit.	Country.	Population.	Number of exchange telephones.	Number of persons to each exchange telephone.	Characteristics of Management.
	GROUP I.				
1	Norway	2,000,917	13,943	144	Very low rates. Local management of exchanges. Good rural intercourse. No competition.
2	Sweden	4,784,981	32,602	147	Very low rates. Local management of exchanges in part. Good rural intercourse. Competition.
3	Luxemburg	211,088	1,315	160	Very low rates. Central management, but with delegated control in some cases to local authorities. Good rural intercourse. No competition.
4	Switzerland	3,000,000	17,422	172	Ditto ditto ditto.
5	Denmark	2,185,335	10,325	211	Very low rates. Local management of exchanges. Good rural intercourse. No competition.
6	Finland	2,412,135	7,351	328	Very low rates. Local management of exchanges. Good rural intercourse. Competition.
	GROUP II.				
7	Imperial German Post Office Territory	41,796,966	93,131	449	Fair rates for urban subscribers in large towns; high rates in small towns. Highly centralised management. Bad rural intercourse. No competition.
8	Bavaria	5,594,982	12,400	451	Ditto ditto ditto.
9	Wurtemburg	2,036,522	4,430	459	Low rates for urban subscribers, but with regulations tending to restrict suburban and rural intercourse. Centralised management. No competition.
10	**United Kingdom**	**37,880,764**	**59,569***	**636**	High rates, with regulations unfavourable to development outside towns. Local management in part. Practically no competition.
11	Holland	4,669,576	7,263	643	High rates in three chief towns; low rates elsewhere. Management chiefly centralised. Bad rural intercourse. No competition.
12	Belgium	6,136,444	8,757	700	High rates in large towns; low rates of recent origin in small towns. Centralised management. Indifferent rural intercourse. No competition.
	GROUP III.				
13	France	38,343,192	26,772	1,432	High rates; subscribers also pay capital cost of their installations, except in Paris and Lyons. Centralised management. Bad rural intercourse. No competition.
14	Spain	17,800,000	10,984	1,618	High rates in large towns. Recently introduced reduced tariff for smaller towns. Local management. Bad rural intercourse. No competition.
15	Austria	23,895,413	14,574	1,640	Fair rates, but subscribers pay capital cost of their installations. Centralised management. Bad rural intercourse. No competition.
16	Italy	30,535,848	12,067	2,530	High rates in large towns, except in Rome, where competition exists; low rates in Rome and in small towns, but under strict Government supervision. Bad rural intercourse. No competition except in Rome.
17	Hungary	17,463,473	5,563 *	3,139	High rates in towns; very low rates in villages, but combined with regulations which tend to restrict communication between towns, suburbs, and villages. Partly local management. No competition.
18	Portugal	5,000,000	1,483	3,371	Exchanges only in Lisbon and Oporto. Fair rates. No rural intercourse. No competition.
19	Russia	97,151,789	7,415	13,102	Highest rates in Europe in chief towns; high rates in smaller towns. Partly local management under Government rules. Bad rural intercourse. No competition.

* Company 58,367; Post Office, 1,202.

to the local authorities, since in 1894 only 10 municipal stations existed in the whole of France. In the Scandinavian countries and Finland, local management has had even freer play, with the highly satisfactory result disclosed in the table. The third town of Norway, Trondhjem (population 30,000), is worked by the municipality most successfully at very low rates.

On inquiring in what manner circumstances differ so gravely in the United Kingdom as to preclude the possibility of small towns and rural communities availing themselves of telephonic communication, it appears that, apart from the want of local control and competition, the inelasticity of the present system of tariffs, which was originally invented for towns, is much to blame. In towns distances are short, and subscribers, if the switchrooms are properly distributed, have seldom to pay more than the unit charge; but in country districts distances of several miles must often intervene between the subscriber and switchroom, and as the annual rental exacted increases rapidly with the distance the charges become piled up by the extra mileage beyond the means of the majority of the population. What is wanted is the application of the Austrian (which with some modifications has also been adopted in Luxemburg) system of tariffs, under which all subscribers, whatever their distance may be from the switchroom, are put on an equality as regards annual subscriptions, the only difference being made in the initial payment on joining the exchange, which varies with the length of line required, the object being to reimburse the owners of the exchange system once for all for the additional cost of the extra mileage. In Austria the annual subscription is the same for any distance up to 15 kilometres (9¼ miles). In Luxemburg the annual subscription, provided the distance of the subscriber from an existing route of wires is not greater than 1½ kilometres—which is seldom the case, so numerous are the lines—is always £3. 4s. per annum, which covers all charges for service and maintenance, and confers the right to talk all over the Grand Duchy, which measures 44 by 30 miles. If a subscriber is situated outside the free radius which surrounds every switchroom, he makes, on joining the exchange, an initial payment, designed to cover the cost of the line which intervenes between the free radius and his place. This is charged at the rate of £4 per kilometre only, and the payment may furthermore, if desired, be spread over five years. If located within the free radius, the subscription is simply £3. 4s. per annum without an initial payment. Comparisons are often instructive, and it will be interesting to examine the differences resulting from the application of this system and that which prevails at home.

In Luxemburg a subscriber located five miles (eight kilometres) from the boundary of a telephone area (provided he is not more than 1½ kilometres from an existing line) will pay: A compensation for extra distance, £5 × £4 = £20 in one payment, or, if he chooses, divided in five annual payments of £4, and thereafter an annual subscription of £3. 4s. If 15 kilometres (9¼ miles) away he pays £15 × £4 = £60 down, or £12 for five successive years, at his option, together with an annual subscription of £3. 4s. He may be taken to pay £15. 4s. for the first five years, and £3. 4s. per annum for all time thereafter. The British Post Office charge £14 per annum per mile, so that a subscriber five miles from a switchroom would be charged £70 per annum in perpetuity, while one 9¼ miles away would pay no less than £134 per annum. The National Telephone Company's charges would be more than this in the metropolitan area and less in the provinces, but always, as experience has amply proved, prohibitive.

The different results aimed at in the United Kingdom and in Luxemburg need, therefore, create no surprise. They are simply examples of cause and effect. It cannot be said that such rates as are applied in Luxemburg do not pay. Accounts and balance sheets have recently been published† which prove that even lower charges

† "The Telephone Systems of the Continent of Europe."

Digitized by Google

are made remunerative by local companies and municipalities in Holland, Denmark, and Norway.

The telephonic development attained in the Aland Islands, the entire population of which numbers but 18,000, has been mentioned. What have we to show at home of a corresponding nature? The Isle of Man (population 55,608) has one exchange. The Isle of Wight (permanent population 78,672, which is much increased in summer), containing seven or eight flourishing towns, possesses no telephonic facilities whatsoever; and the Channel Islands (population 92,234) are in equally bad case, although both Jersey and Guernsey are places in which a good telephone system would be of the utmost value, owing to the necessity the farmers are under, especially at certain seasons, of maintaining good communication with the ports, St. Helier's and St. Peter's. Exchanges in these towns alone would be next to useless; it is necessary to bring the outlying villages and scattered farmsteads into connection with them, and as this would necessitate many lines of from two to five miles in length, the existing tariff both of the Post Office and National Telephone Company are prohibitive and impracticable in a ludicrous degree. But an intelligent application of one or other of the Norwegian, Finnish, or Luxemburg methods would speedily cover the islands with telephone lines, and that with profit both to the servers and the served. The cases of Jersey and Guernsey have, unfortunately their parallel in most of the country districts in the three divisions of the United Kingdom.

One of the Norwegian companies—the Drammens Uplands—affords a striking example of profitable rural telephony. The area for which it holds a concession from the Government extends over five counties and measures 143 miles from north to south, the most important places served being the villages called Kongsberg and Hönefros. At the end of 1894 the Company possessed 24 switchrooms, 292 subscribers, 478 miles of poles, 1,553 miles of lines, including 671 miles of metallic circuits. Its annual subscription, which covers a line not exceeding 2 kilometres in length, and the right of free conversation over the whole of the five counties, is only £5. 11s. 1d. Its capital account stood at £9,815; its receipts from all sources of the year amounted to £2,332; the net profit was £752 and the dividend 6 per cent. This dividend has been paid regularly during the five years of the Company's existence, and a deterioration and reserve fund built up besides. These are facts which should surely plead against the present era of telephonic stagnation.

The technical features of the Continental systems are, as a rule, best where the tariffs are lowest and the extension of communication greatest. The conditions laid down by the author in his Paper on "The Telephoning of Great Cities," read at the Cardiff meeting of the British Association in 1891, as being necessary to a well-ordered exchange, are fulfilled more nearly in Sweden than elsewhere, especially by the General Telephone Company, which operates in Stockholm and a radius of 43½ mile around. Metallic circuits are universal; special attention is given to prompt switching, and Stockholm is divided into eight nearly equal divisions, each containing a switchroom. The prompt and economical addition of new subscribers is thus rendered easy. The speed achieved in switching is that stated in the Paper to be practicable and proper in a good exchange—viz., 10sec. The countries comprising Groups II. and III. are, with some exceptions, technically behind those of Group I. The reason lies on the surface. The conditions which prevail in Group I. bring about rapid extension; rapid extension involves the solution of problems which do not present themselves while exchanges are in their infancy, and the solution of such problems evolve superior engineers.

THE ONTARIO DRAIN TUNNEL AND ELECTRIC PLANT.*

BY C. R. MC KAY.

The adverse financial conditions which have prevailed during recent years have cut with peculiar keenness into the profits of the silver mining industry, and those mines which can now be profitably worked are exemplifications of the survival of the fittest. Their vast mining and milling plants call for the exercise of almost all branches of science and engineering. Probably no mine system in the world possesses more features of interest and instruction than the Ontario and Daly mines, worked in conjunction under one ownership, and located near Park City, Utah, in the Wahsatch range. The recent completion of the Ontario drain tunnel and the utilisation of its waste water to furnish electric light and power for the numerous works and mills of the Companies present some features which seem to justify description, and which may convey valuable lessons to those engaged in similar projects.

The Ontario has four vertical shafts, only two of which are at present actively used, the several shafts having been sunk in order to reach the ore bodies in the most convenient and economical manner. The shafts now used are No. 2 and 3, the former being at present 1,500ft. in depth and the latter 1,100 feet. The underground workings of these mines have attained such vast dimensions, that if placed end to end, they would form a continuous tunnel nearly 60 miles long.

The chief difficulty and expense encountered during the operation of this mining enterprise has been the disposition of the water which pours into the underground excavations from subterranean reservoirs and streams. Two means only existed by which this could be controlled, these being the continual operation of large and numerous pumping engines, and the cutting of tunnels from the lowest available point of the workings to some surface location which afforded natural drainage for the final disposition of the flow. Either method, of course, involved great expense.

When Ontario shaft No. 3 had reached a depth of 600ft., the quantity of water had become so formidable that considerations of economy impelled the management to run a drain tunnel from the bottom of that shaft to a point nearly a mile distant, through which the drainage was carried off. For several years this tunnel proved equal to the requirements, and resulted in great saving to the Company; but, as the shafts went deeper and the lateral workings extended, the water again became an intolerable burden, and far more serious than ever before, for at this time the Ontario was operating much deeper than any of the surrounding mines, and the ramifications of its underground work had assumed such proportions that not only had the local water greatly increased, but the mines located round about, and, in fact, the entire neighbouring country, had begun to drain into the lower workings of the Ontario. In one case a large adjacent mine which had been unable to contend against the water, and had been closed down on that account, became absolutely dry, and remains so to-day. When the Ontario had reached a depth of 1,200ft. it became necessary to run a new drain tunnel, and to locate it at a depth sufficient to provide for extensive operations in the future.

The decision, as finally made, was to run eastward from the 1,500ft. level of No. 2 shaft, the total length of the tunnel being approximately three miles. It was expected that six years would be required to complete the work, and that the cost would approximate $500,000.

Work was begun on this tunnel July 25, 1888, at the east end. The first 300ft. were driven entirely by hand, during the erection of machinery at the mouth of the tunnel. During November, 1891, a tremendous body of water was encountered, which drove out the men from the face. Bulkheads were useless. Nothing could restrain the flow, and all that could be done was to wait for the water to exhaust itself. The volume was so great that for a distance of 9,000ft. the track had to be raised, because of the insufficient water way, and parts of the track were entirely washed out. Seventy-one days were lost before work at this point could be resumed. As the tunnel neared completion, it became evident that the flow of water therefrom would be permanent and of considerable amount, though no means existed by which the normal flow for the future could be accurately foretold. However, the quantity of water handled by the pumps during past years was known with reasonable accuracy, as was also the decrease in that quantity due to the approach of the face of the new drain. Measurements of the flow at the tunnel mouth had been made from time to time, and comparison of these various sets of figures gave some indication as to the future discharge, and showed that opportunity existed for securing additional conveniences and economy by utilising the water at the tunnel mouth, where a short and steep fall was readily available.

The idea of electrically transmitting this waste energy to those distant points where it could be usefully applied was adopted by Superintendent R. C. Chambers, and the matter of designing and constructing a suitable plant was referred to the writer. Surveys and measurements made at this time, while the tunnel was yet several hundred feet from completion, showed a steady flow of water amounting to about 800 cubic ft. per minute, and an available fall close to the tunnel mouth of 125ft. in 380ft. The general opinion was that a decrease would take place in the near future, but many facts and figures convinced the engineer in charge of the work that a permanent increase would occur in the flow at the mouth. Accordingly a plant was decided upon of sufficient capacity to furnish light to all of the hoisting works, mills, and dwelling houses belonging to the Ontario and Daly mining companies, and sufficient power during the day to drive the machine shops of the mines and mills. No underground lighting was attempted. The choice of a route for the transmission line lay between an overhead line, following a well-travelled road through cañons for a maximum distance of about 6½ miles, and an underground line through the tunnel, to a point well adapted for a centre of distribution, and offering advantages in saving of copper and ease of inspection. The overhead route was considerably the longer, involved a somewhat wider distribution of lead along the main line, and exposed the line to extremely heavy winter weather and to frequent and

* Abstract from the *Engineering Magazine*.

Digitized by Google

severe storms during summer. This route was easy of inspection throughout, except in winter weather. The underground route presented the advantages of a shorter line, greater facilities for uniform voltage throughout the system, and absolute protection of the transmission from bad weather and lightning; the entire main line, too, could be inspected and repaired by a workman without dismounting from a tram car. On the other hand, the cost of erection and danger of accidental contact were greater, and the maintenance of proper insulation of the line seemed impossible, owing to the floods of water falling from the roof and timbers of the tunnel, the frequent shifting and breaking of timbers, and the great number of insulating supports required for mechanical strength. Therefore the overland route was chosen for the transmission.

The hydraulic plant is located about 1,600ft. from the mouth of the drain tunnel. The water is conveyed through a wooden flume and ditch to a pressure tank, there being also an overflow ditch with adjustable gate for disposing of surplus water. The pressure tank is provided with a settling compartment and racks for catching drift contained in the water. From the pressure tank is led a wrought-iron pipe of varying diameter. The prime mover is a 3ft. Pelton wheel calculated to deliver on the main belt 90 H.P. when running at 280 revolutions per minute under 120ft. effective head.

The conditions to be fulfilled in the selection of a type of electrical equipment for this plant removed all direct-current systems from consideration. The choice lay between the various alternating single and multiphase systems, generating the maximum line voltage directly, and supplying reducing transformers at various points along the main line. The "monocyclic" system was adopted by reason of great simplicity of the system as a whole, its freedom from lack of balance between the different circuits, the ability to successfully operate self-starting motors of a simple and well-tried type, as well as arc and incandescent lights, and, finally, its first cost, which in this case was less than for any other system excepting the three-phase. The electrical equipment of the power house includes an eight-pole 60-kilowatt "monocyclic" alternator, driven at 900 revolutions by a 12in. belt from the pulley on the wheel shaft. This dynamo at no load generates 2,200 volts at 60 cycles per second, and normal excitation is supplied by an Edison bipolar shunt machine driven from the alternator shaft. The dynamo is over-compounded to furnish 2,500 volts with a full load current of 25 amperes.

From the terminals of the generator three main leads are taken to a skeleton switchboard, on which are located switches, rheostats, indicators, lightning arresters, and a gauge indicating the pressure of the water supplied to the wheel below. All wiring between the dynamo and switchboard is carried beneath the floor of the dynamo room on porcelain insulators in plain sight. The engineer has full control of the entire system without leaving the side of the switchboard.

The transmission line covers a total distance of 6½ miles, and traverses a very rough and broken country, rising at one point to nearly 9,000ft. above sea level. The entire line, however, was located so as to obtain good sun exposure at all times. The poles are of red pine. The loss in the transmission at full load was calculated at about 11 per cent. between the power house and the centre of distribution. The insulation resistance of the system is remarkably high.

The total number of 16 c.p. lamps connected with the system is 700, all supplied at 110 volts. The problem of securing proper distribution of light in the various mills and hoisting works was very successfully solved by a suitable arrangement of the incandescent lamps. The arc lights formerly in use were very unsatisfactory, being difficult to maintain, owing to constant exposure of their mechanism and to clouds of metallic dust and steam, and especially objectionable because of localising the light and casting numerous dense shadows. The wiring and fixtures in the mills are subjected to very unfavourable working conditions. The most objectionable feature is the effect of metallic dust, steam, and sulphuric acid vapours upon exposed metal surfaces, and upon the insulation of the wire. Frequent testing has failed, however, to indicate any grounds or short-circuits. Hard rubber waterproof sockets are used throughout the mills, and the lights are tapped directly on the supply branches without rosettes, the branches being protected by switches and cut-outs in sheltered places.

There are three motors connected to the system, two of 15 H.P. each and one of 25 H.P. The 15 H.P. motors drive the machine shops of the Marsas Mill and the Ontario Mine; the large motor is located in the saw mill at Ontario No. 3 shaft.

On February 24, 1895, the plant was started. A trial run failed to develop any defects throughout the entire installation. On the following day, during a heavy storm of snow and sleet, the entire load of lamps connected with the system was thrown on. The performance, under load, of the installation in the power house was thoroughly satisfactory. The dynamos ran smoothly and quietly, and failed to show any evidence of heating in any part. This lack of heating has characterised their performance at all times since the beginning of operations.

The method of furnishing excitation to the generator in a plant of this character is a factor of vital importance in securing close regulation. It may be stated as a general rule that, where the normal field strength of the generators is a function of their speed, close regulation of voltage for large and rapid fluctuations of load is impossible to attain in a water-power plant. To insure constant excitation the exciting machine should always be driven by a separate water-wheel where the conditions permit of such arrangement.

The plant has run constantly since its completion without interruption or repairs of any sort, barring the breakage of the exciter shaft by a tight belt shortly after the start. The accident caused interruption of service for 12 hours only, and was purely a result of carelessness.

During the month of June some interesting experiences occurred with lightning. On one occasion an electric storm of great intensity prevailed along parts of the line most distant from the power house. During the space of a half hour no less than 13 separate strokes of lightning came into the switchboard from the main line, all of these being successfully discharged by the arresters. The final discharge, however, was of such severity as to start an arc between the discharge points of the arresters on the two main wires. This arc of comparatively low resistance immediately short-circuited the dynamo through a portion of the large copper strip used as a ground connection, and the machine ran in that condition for fully 10sec. before being disconnected. No damage whatever was sustained by the dynamo. The two arresters, however, were rendered absolutely useless, the brass discharge knobs being completely melted down, and several were fused together. After removing the damaged arresters, the dynamo was again started, and no further difficulty was encountered.

Two engineers are employed to operate the Ontario electric system, each of whom runs the plant 12 hours daily. No labour is involved, and, owing to the steadiness of the load both day and night, the attention required in the power house is limited to the inspection of oil in the various bearings and the starting and stopping of the plant at the beginning and end of each run, at which time the machinery is wiped off. The motors require no attention during their operation. The entire system at any instant involves only the attendance of the engineer at the power house, who also makes any slight repairs or alterations required from time to time throughout the distribution. The operating expenses therefore practically include only the engineer's pay, occasional minor supplies and lamp renewals.

The total cost of the Ontario system is a matter of gratification when viewed in comparison with recent figures showing cost of similar installations elsewhere, and in view of the diversity of service and economy of attendance secured. The saving effected by the installation is somewhat difficult to estimate accurately because of the large additional service hitherto unpossessed by the Company. The interest account is somewhat higher than that charged against the old arc-light plant. The labour account for the service now rendered by the present plant is very considerably reduced, some income is already derived from the sale of current for lighting, and the amount saved annually in fuel and illuminating oil exceeds $3,000.

The great drain tunnel is being extended through the Ontario ground to the Daly mines, and a continuation of work has resulted in a notable increase in the flow of water available at the power house, the amount being at present about 1,500 cubic feet per minute. Negotiations are nearly completed for doubling the installation at the power house, with the object of providing a reserve unit in case of breakdown, and of selling current by contract to a local organisation for lighting and incidental power service in Park City. The extension of the plant will involve but comparatively small outlay and labour, and the attendance will not be increased. It is, therefore, confidently expected that the plant will be made to earn dividends, in addition to furnishing its present service free of cost to the owners.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *August 31, 1895.*

Engineering Education.—The Society for the Promotion of Engineering Education will hold its second annual meeting at Springfield, Mass., on Monday, Tuesday and Wednesday of next week. This Society was organised at Chicago during the World's Fair, and is in a very flourishing state. As a rule college jealousies in this country prevent co-operation in educational work, but our professors of engineering seem to be free from this narrow spirit, judging from the very general manner in which they participate in the proceedings of this

Digitized by Google

Society. The programme of the coming meeting contains 17 items, including 31 Papers. Prof. D. C. Jackson will read a Paper on "Electrical Engineering" and Prof. George D. Shepardson one on "Teaching Industrial Applications of Electricity," while several of the others will also be partly devoted to electrical engineering. An interesting part of the proceedings will be the reading and discussion of Papers criticising American engineering schools, contributed by Prof. Ritter of Zurich, Prof. Hele-Shaw of Liverpool, Prof. Voit of Munich, Prof. Goodman of Leeds, Prof. Unwin of London, and Prof. Bunt of Carlsruhe.

Electrical Combinations.—A decided tendency has been manifested in large cities towards combining under one management the various electric street railway lines. This has been done to a large extent in Brooklyn and more recently in Philadelphia, and a movement is now on foot in St. Louis to combine under one management all of the street railways and under another all of the electric lighting companies. This latter combination is, however, rather an unusual one, as heretofore the Edison Illuminating Companies have held aloof from alternating and arc lighting companies. While such consolidations may doubtless result in a reduction of expenses, yet it is quite probable that the real motive lies in the opportunity afforded for stock watering. The tendency of all American corporations is to keep down dividends to the minimum by increasing the capitalisation, and frequently the ingenuity of capitalists is taxed to insure the carrying out of such a programme, and gives rise to the numerous re-organisations and consolidations to which large corporations in this country are subjected.

Conduit Railways.—It is reported on good authority that another of the large horse railways of New York City will soon commence to change over to electric traction, using a modified Budapest system. It is also being persistently rumoured that the Metropolitan Cable Company, which controls the Broadway and other lines, will also before long discard the cable and instal a system similar to that now employed on Lenox-avenue, which is practically the same as the one so successfully in use for more than five years at Budapest, Hungary. It seems very probable that during the next few years underground conduit electric-traction systems will be very largely adopted in our principal cities. The result of this, however, promises to be disastrous to electric railway interests in smaller cities on account of the pressure that consequently will be brought to bear by the public to obtain the substitution of electric underground conduit traction for trolley systems.

CORRESPONDENCE.

GENERAL FORMULA FOR THE MAGNETIC FORCE AT ANY POINT IN THE PLANE OF ANY POLYGONAL FIGURE.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Referring to the interesting Paper of Prof. G. M. Minchin in *The Electrician* of September 6th, it can be easily seen that the result (5) is only a particular case of a more general formula, applicable to any kind of polygonal figure. Keeping the same notation, but supposing the angles B C D A to be respectively a_1 a_2 a_3 a_4, and applying the same elegant way of calculating, we shall find, as the expression of the magnetic force in any point of the plane,

$$F = \Sigma \frac{\sin a}{p}.$$

This result, of course, reduces itself to the result (5) when the figure is a rectangle, *i.e.*, when the angles a are right angles.

If we consider a plane curve as a polygonal figure of an infinite number of sides, we get, as an expression for the magnetic force,

$$F = \int \frac{ds}{r \rho \cos \theta}.$$

ds = element of arc;
ρ = radius of curvature;
r = distance from the point where the force is being calculated to the element of arc;
θ = angle between r and ρ.

Many interesting consequences could easily be drawn from both these formulæ.—Yours, &c., Osc. Colard.

Brussels, September 10, 1895.

MAGNETIC UNITS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: As a past student under Dr. Sumpner, I certainly agree with what he says in your issue of September 6th. I know how I used to get muddled over B, H, N, L, quadrant, henry and secohm (to say nothing of μ and π). If names of past celebrities, often twisted beyond recognition, are to be given to strange units, where will the poor student of the future be? There are bound to be international differences as to the names to use; and even if such universally popular names as Faraday and Thomson (British or American as you please) are used, can it be supposed that the "diminished editions" of these names are beautiful or have anything (saving sentiment) to recommend them? Do *farad* and *thom* even recall much of the people they are intended to represent? The whole subject of units requires years of discussion and arbitration before any system can confidently be decided upon.—Yours, &c., C. M. Mayson.

September 11, 1895.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: It appears from the letters recently published in your columns that many of your correspondents, including Prof. Silvanus Thompson, continue to measure magnetic flux in lines. This is scientifically inaccurate, as the dimensions of magnetic flux are $L^{\frac{3}{2}} M^{\frac{1}{2}} T^{-1}$, and the dimension of a line is L.—Yours, &c., J. A. Kingdon.

29, Marlborough-hill, N.W., Sept. 16, 1895.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

SPECIAL NOTICE.—The 1895 (thirteenth) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is READY. In addition to the old well-known features of the book, which are brought up to date, a quantity of new and useful matter has been added, rendering the book more than ever indispensable to the Electrical, Engineering, and Allied Trades. Price, 7s. 6d., post free 8s. 3d., abroad 9s.

The Edition for 1896 is in active preparation, and orders for Advertisements and Subscriptions can now be sent in.

NEW BOOKS AND EDITIONS.

The following New Books and Editions of "The Electrician" Series *can be obtained of the Booksellers or direct from the Publishing Offices :—*

Laboratory Notes and Forms.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"The Work of Hertz."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"Electric Lamps and Electric Lighting," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

A Large-Sheet Table, giving full particulars of the Electricity Supply Stations throughout the Kingdom, can now be supplied mounted on stout board, with cord for hanging. Price: Varnished, 3s. 6d.; Unvarnished, 3s. —each post free. A Map showing positions of Supply Stations throughout the country is mounted on the back of the Table, and a Coloured Map of Metropolitan Electric Lighting Areas and a large sheet of Electricity Supply Statistics are also mounted on some copies, the price of which complete, post free, is 5s.

Digitized by Google

A Sheet Table showing Total Capital Outlay and Receipts and Expenditure for the year 1894 of the Statutory Electric Supply Undertakings of the Metropolis is now ready, printed on thick paper, price 6d.

A Sheet Table giving similar particulars in relation to Provincial Statutory Electric Supply Undertakings is now ready, printed on thick paper, price 6d.

"Electric Motive Power."—A new work, by Mr. Albion T. Snell, with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"Electrical Engineering Formulæ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"Drum Armatures and Commutators."—By Mr. F. Marten Weymouth, is also ready; price 7s. 6d (abroad 8s.). Prospectus on application.

"The Incandescent Lamp and its Manufacture."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

Tenders Invited.—The Corporation of Eccles invite tenders for the supply and erection of Lancashire boilers, alternating-current dynamos and engines, cables, street boxes, &c , and transformers. Plans, specifications, &c., may be seen at the offices of the Town Clerk, or of the Consulting Engineer (Mr. S. V. Clirehugh), Temple Chambers, Brazennose-street, Manchester, on and after the 18th inst. Tenders must be sent in to Mr. Geo. Wm. Bailey, Town Hall, Eccles, by 12 o'clock noon on the 30th inst. Additional information is given in our advertisement columns.

———— The Asylums Committee of the London County Council invite tenders for the erection of fire alarm and telephone systems at their asylums at Banstead, Surrey, and Colney Hatch, London, N. Tenders by 12 o'clock, 30th inst.

———— The Electric Lighting Committee of the Harrogate Corporation require tenders for the supply and erection of the following plant:—(*a*) Lancashire boilers, economiser, feed pumps and accessories; (*b*) steam alternators, condensers, fittings, &c., steam exhaust feed and sundry pipes, valves, &c.; (*c*) switchboard and instruments; (*f*) transformers and accessories; (*g*) meters; (*h*) overhead travelling crane. Specifications may be obtained from the Borough Surveyor, Harrogate, and tenders, addressed to the Town Clerk, Municipal Offices, Harrogate, must be delivered on or before the 30th inst. Further particulars are given in our advertisement columns.

———— The Building Committee of the Harrogate Corporation invite tenders for wiring the new Montpellier Baths for the electric light. Specifications, &c., may be obtained from the architects (Messrs. Baggalay and Bristowe), 66, Victoria-street, London, S.W., and tenders, addressed to the Town Clerk, Municipal Offices, Harrogate, must be in by the 30th inst.

———— The Board of Control, Dublin, require tenders for the supply and erection of two direct-coupled steam engines and dynamos, a battery of accumulators, main switchboard, &c., for the lighting of the Purdysburn Asylum, Belfast. Tenders to Secretary, Board of Control, Custom House, Dublin, by 28th inst.

———— The Dundalk Town Commissioners invite tenders for the erection and maintenance of the necessary plant for lighting the town by electricity from July 1, 1896. Tenders by October 7th.

———— The Queenstown Town Commissioners require tenders for the erection of works and the necessary plant for generating electric current for the public and private lighting of the town. Tenders by Thursday next, the 26th instant.

———— The Corporation of Dewsbury invite tenders for wiring the public baths and library for the electric light. Tenders must be in by 12 o'clock noon to-morrow (Saturday).

———— The Baden State Railway authorities invite tenders for the supply of a quantity of telegraph poles. Tenders to the Gr. Hauptverwaltung der Eisenbahnmagazine, Gr. Badische Staatseisenbahnen, Carlsruhe, by the 23rd.

———— The municipal authorities of Tongres, Belgium, invite tenders for the concession for the public and private electric lighting of the town. Tenders to the Administration Communale by October 10th.

———— The Director of the Grand Cercle at Aix-les-Bains requires tenders for supplying electric current for an installation of 1,200 lamps. Tenders to M. le Directeur du Grand Cercle, Aix-le-Bains (Savoie), France.

———— The Leeds Guardians require tenders for providing and fixing some new, and repairing other, lightning conductors at their workhouse premises in Beckett-street. Tenders, by the 24th inst., to the Clerk (Mr. J. King), Union Offices, East Parade, Leeds.

———— Tenders are required for installing the electric light at Wagstaffe's Steam Preserve Works, Hurst Brook, Ashton-under-Lyne.

Tenders Invited.—The Directors of the Great Western Railway Company invite tenders for various stores from November 1st next to October 31, 1896, and amongst these are telegraph instruments, india-rubber goods, copper, iron and steel wire, telegraph ironwork, tools and drysalteries, electric light carbons, copper, zinc, &c., pipes, screws, bolts and rivets, iron and steel tubes, telegraph poles and yellow pine, &c. Tenders, addressed to Mr. G. K. Mills, Secretary, Paddington Station, W., must be in by October 7th.

Tenders Accepted.—The Bedford Town Council have received the following tenders for the supply of vulcanised rubber cables:—

	£	s.	d.
W. T. Henley's Telegraph Works Company (London) (*accepted*)	£1,797	13	3
India Rubber Company (Silvertown)	2,077	16	4
W. T. Glover and Co. (Salford)	2,131	7	1
Siemens Bros. and Co. (London)	2,158	12	11
Telegraph Manufacturing Company (Helsby)	2,582	6	8

———— Four tenders were received by the Huddersfield Industrial Society for installing the electric light in their boot and shoe and confectionery departments. The tender of Mr. T. W. Broadbent, of Huddersfield, has been accepted.

———— The Metropolitan Asylums Board have accepted the tender of Mr. Thomas Beeley, of Hyde, for supplying three boilers at the new Brook Hospital for £1,407. 15s.

Tenders Received.—Some time ago the Leyton District Council decided to light their Public Offices and Technical Institute by electricity, and they commissioned Prof. H. Robinson to obtain tenders from 13 of the best electrical firms. Nine tenders have now been received by the Council, but four of the 13 firms originally selected by Prof. Robinson declined to tender. Separate tenders were sent in for the Public Offices and the Technical Institute:—

	Public Offices.			Technical Institute.		
Drake and Gorham	£573	14	2	£382	7	4
Paterson and Cooper	500	10	3	359	7	8
Sharp and Kent	630	15	4	402	5	2
Crompton and Co.	660	13	5	543	2	1
Strode and Co.	493	3	3	323	13	2
Joel (H. F.) and Co.	510	13	5	324	7	3
Brush Company	472	5	11	306	15	9
Spagnoletti (J. E.) and Crookes	475	8	0	315	12	0

All of London.

The tenders have been referred to the General Purposes Committee for consideration and report.

———— The Wakefield Corporation have received 40 tenders for the supply and erection of plant for their electricity supply station, and these have been referred by the Electric Lighting Committee to Mr. R. Hammond, consulting engineer, for analysis and report.

Appointment.—Mr. Laurence M. Waterhouse, A.I.E.E., of Aberdeen, has been appointed lecturer in electrical engineering, telegraphy and telephony at the Croydon County Polytechnic. He previously held a similar position at the Municipal Technical School at Brighton. Mr. Waterhouse was also for some time with the "P. and O." Company as electrician on some of their steamships. He holds the full technological certificate of the City and Guilds of London Institute in electric lighting with first-class honours. In 1890 he was medallist in the Electrical Department at the Heriot Watt College, Edinburgh, under Dr. R. Mullineux Walmsley.

———— Mr. E. F. J. Hewlett, M.I.E.E., has been appointed electrical engineer to the Rockhampton Gas and Coke Company (Limited), Rockhampton, Queensland. Mr. Hewlett was previously employed by the Hove Improvement Commissioners, and was for some time engaged by Messrs. Siemens Bros. and Co.

Appointment Vacant.—The City and Guilds of London Technical College require an assistant demonstrator in the electrical engineering department. Salary £80 per annum. Apply to the Principal, Leonard-street, Finsbury, E.C.

Dissolution of Partnership.—By mutual friendly agreement Mr. S. P. Tatham has retired from the partnership of "Girdlestone, Tatham and Co." of Davies-street, Berkeley-square, W., as from the 31st August last. The remaining partners will carry on the business under the style and title of "Girdlestone and Co.," who have made an arrangement for retaining Mr. Tatham's services.

———— Messrs. W. Jeffery and F. Taylor, who have hitherto carried on business as electrical engineers under the style of Jeffery, Taylor and Co., at 11, Queen Victoria-street, London, E.C., have dissolved partnership.

New Firms.—Messrs. R. F. Venner and A. M. Sillar have entered into partnership and will carry on an agency business at 10, Delahay-street, Westminster, S.W. The new firm will act as sole agents for the "Hookham" electricity meters (Birmingham and District excepted) and for the Nalder and Harrison Construction Syndicate (Limited).

Digitized by Google

BANKRUPTCIES.—We give below a list of the principal creditors in the bankruptcy of Thomas Watts Scott, trading as an electrical engineer, under the style of T. W. Scott and Co., at Broad-street, Birmingham :—

General Electric Company, London	£108	0	0
Glover (W. T.) and Co., Manchester	41	0	0
Electric Construction Company, Wolverhampton	40	0	0
India-Rubber Company, London	34	0	0
Blackman Ventilating Company, London	16	0	0
Verity (B.) and Sons, London	12	0	0
Bourne and Grove, Worcester	11	0	0

——— A receiving order has been made in the estate of Dr. Joseph Whatmough, trading as an electrical engineer under the styles of D. J. Whatmough and T. and P. Dyer at 39 and 40, High-street, Oldham.

LIQUIDATION.—The order for the winding-up of Dalziel's News Agency of America (Limited) was made in December last, and the summary and observations now issued by the liquidator state that the Company was incorporated in 1891, with a capital of £100,000, to acquire from Dalziel's Cable News Agency (Limited) (in the prospectus styled the parent company) its interest in an American company known as Dunlap's Cable News Company, together with the business and goodwill of the parent Company in the United States. Accompanying the prospectus was a report from Mr. Dalziel which estimated the profits at £30,000 per annum. It would appear from the deficiency account now published that instead of earning this handsome profit the Company's trading resulted in an average loss of about £20,000, calculating from the date of incorporation to the date when the Company ceased business. The unsecured liabilities amount to £33,908. 19s. 5d., and of this sum £18,758. 2s. 1d. is due to the petitioning creditors (Messrs. Hallett and Co.) and £12,319. 2s. 3d. to Dalziel's Cable News Agency (Limited). There are no available assets, and as to the contributories, the total deficiency is stated to be £76,058.

B.A. STANDARD SCREW THREADS.—Messrs. Lehmann Brothers, of 38, Hampshire-street, Torriano-avenue, London, N.W., send us their latest price list of British Association Standard Screw Threads. Copies of the price list can be obtained on application.

CHLORIDE STORAGE BATTERIES.—The Chloride Electrical Storage Company (Limited) have just issued a new edition in pocket form of their battery catalogue. This edition has been considerably revised and enlarged. It is neatly printed, and contains full information as to capacity, weights, dimensions, &c., and gives illustrations of several types of plates. Those firms interested can obtain complete copies of the catalogue on application to the Company.

GENERAL ELECTRIC COMPANY.—This Company inform us that, as owners of Patent No. 3,664 (dated February 28, 1891), entitled "Improvements in Electrical Switches," they have granted licences for the manufacture and sale of their well-know "Tumber or Link" switches (with either a link movement or a heel piece) to the following firms: The Edison and Swan United Electric Light Company, Messrs. Evered and Co. (Limited), W. McGeoch and Co., B. Verity and Sons, Bayley Bros., and Tucker and Co.

ELECTRIC TRANSMISSION OF POWER.—We recently received from the Electrical Company (Limited) of Charing Cross-road, a well got up pamphlet containing full particulars and prices of all the machinery and apparatus sold by them. Useful instructions are given with regard to systems and the working of the various dynamos, motors, &c., &c., the three-phase system being especially well treated. The manual is well illustrated, and useful tables are plentiful. It contains a good deal of information likely to be required by an intending purchaser of electrical plant.

CATALOGUES.—We have before us the eleventh edition of the Electric Bell catalogue and the sixth edition of the Telephone catalogue of the General Electric Company. These have each been considerably enlarged. In addition to the prices, illustrations, and descriptive letterpress, each list contains a practical treatise upon its particular branch and a copious index.——A comprehensive catalogue of their rocking, stationary and forced-draught furnaces has been forwarded to us by Messrs. Caddy and Co. (Limited), of Daybrook, Nottingham. The book commences with some useful remarks on the use of firebars, and on their efficient and inefficient arrangement. There are a number of well-executed views of the works and apparatus, as well as portraits of members of the directorate, &c., of the Company. Some results of tests are included in the book, and appear to be of a highly satisfactory nature.

ELECTRO-HARMONIC SOCIETY.—A smoking concert will take place at the St. James's Hall Restaurant (Banquet Room), Regent-street, London, W., on Saturday, the 28th inst.

ALLEGED THEFT.—Charles Lucas, described as an electrician, of Hanover-street, Islington, was charged on Monday at the Westminster Police Court with stealing 200 yards of copper wire (valued at £4) from Mr. T. Pritchett, of Soho-square, W. The wire was alleged to have been taken from a house in Wilton-place, Knightsbridge, where the complainant's firm were fitting up fittings, &c., for the electric light. The prisoner, who pleaded not guilty, was sent for trial.

AMERICA CUP.—The Commercial Cable Company provided special means of telegraphic communication between England and France for the International Yacht Race held off Sandy Hook last week. The Company's steamer, "Mackay-Bennett," was specially detailed for this work. The Postal Telegraph Company, from the same steamer, forwarded telegrams to all parts of the United States and Canada. Few sporting events have occasioned more interest—or ended more unsatisfactorily.

ARGENTINE REPUBLIC.—It is stated that the various railway companies have been requested to fix a rate for the transport of all Post Office telegraphic material.

AYR —The Finance Committee recommend that the Commissioners apply to the Secretary for Scotland for authority to borrow an additional sum of £5,000 for electric lighting purposes.

BATH.—At the meeting of the City Council on Tuesday it was decided, on the recommendation of the Lighting Committee, to apply for an electric lighting Provisional Order. Some time ago the City of Bath Electric Lighting and Engineering Company, who have hitherto been supplying electric current in the city, applied for the Council's consent to their application for a Provisional Order, but this was refused. Alderman Clark, who moved the adoption of the Committee's report, said he considered it desirable that the city should be in a position to supply electric current.

BRANDON AND BYSHOTTLES.—A special meeting of the District Council was held on Tuesday to consider the lighting question. The surveyor estimated the cost of lighting the district with oil or gas lamps at £265 or £280 per annum. The Chairman (Mr. W. B. Charlton) thought the question of lighting by electricity should be considered, and added that they might be able to enter into an arrangement by which they could obtain spare steam power from some of the neighbouring collieries, and thus be able to generate and supply electricity at a very cheap rate. After a long debate it was decided to invite the Corlett Electrical Engineering Company to report upon and estimate for the lighting of the principal streets by electricity.

CARDIFF.—A proposal has been made to light the arcade electrically, and the Corporation have instructed the Borough Engineer to report upon the matter.

CHEADLE (STAFFS.).—A public meeting of the ratepayers was held last week for the purpose of considering the proposal of Messrs. Philips and Co. for supplying current to light the "town quarter" by electricity for 14 years at £300 per annum. The Chairman (Mr. T. B. Cull) moved a resolution that the offer be accepted. Dr. Mackenzie moved an amendment that arrangements for lighting the town should be made for one year, but that the Council should in the meantime make inquiries as to the cost of the electric light. Considerable discussion followed, and eventually the amendment was carried by 47 votes to 28.

CHURCH LIGHTING.—St. Mark's Church, Tunbridge Wells, is being wired and fitted up for the electric light. The work has been entrusted to Messrs. Gilbert and Co., 35, High-street, Kensington, W.

CITY AND SOUTH LONDON RAILWAY.—It is stated that negotiations are in progress for the purchase of property necessary for the extension of this railway from its terminus in King William-street to Moorgate-street, near the Metropolitan Company's station. In addition to the terminus at Moorgate-street it is proposed to have an intermediate station on the site now occupied by the church of St. Mary Woolnoth, at the junction of Lombard-street and King William-street. It is added that it will not be possible to carry out the extension within the period allowed by the Act of Parliament, and further time will have to be applied for.

CITY OF LONDON COLLEGE.—We have received a syllabus of the lectures to be delivered in the engineering department of this college during the ensuing session. Mr. H. Adams has charge of the department, and the subjects include civil and mechanical engineering, building and machine construction, &c.

ELECTRICAL COAL CUTTING.—Last week a number of gentlemen connected with the colliery industry were invited to East Plean Colliery to witness the working of an electrical coal-cutter patented by Mr. Hurd. The machine was worked downhill on an incline varying from 1 in 5 to 1 in 10, cutting 3ft. 6in. deep at the rate of about one yard in two minutes. The cutting being carried on at night, the visit was somewhat short, but those present expressed themselves as satisfied with the work done during the limited time at their disposal. The machine has been working at East Plean for some months.

ELECTRIC TRACTION IN SWITZERLAND.—It is proposed to continue the Bremgarten-Wohlen Electric Tramway as far as Fahrwangen. A system of electric tramways is also about to be constructed in Lausanne. The contract for the electrical plant has been secured by the Société de l'Industrie Électrique (Geneva); that for the

Digitized by Google

cables by the Société d'Exploitation des Cables Electriques (Cortaillod), while the rolling stock will be supplied by the Neuhausen Works.

Exeter.—The City Council recently decided to purchase the Exeter Electric Light Company's undertaking, and appointed a sub-committee to report on the condition of the plant at the generating station. The city surveyor (Mr. D. Cameron) reported to the Sub-Committee that he found some of the machinery in good order, and, with the exception of a small high.speed engine, it could be economically worked. He estimated the value of the undertaking at £7,556, but recommended that an electrical expert's opinion be obtained. Accordingly Dr. J. A. Fleming, University College, London, was consulted as to whether the Corporation would be well advised to purchase the works for £10,000, and if that sum was a proper value, and if not, whether it would be advisable for the Corporation to acquire the Provisional Order and the undertaking of the Company. In the report just presented by Dr. Fleming he states that, in his opinion, the present works are not calculated to meet all the requirements of a municipal system of electric supply. The plant, with some small possible extensions which he suggested, would not be sufficient to meet more than an additional demand for 2,000 8 c.p. lamps to be added to the circuit, and the limit of the supply capacity would be an additional 8,500 8 c.p. lamps. His general opinion of the generating station and its equipment was that it was not originally planned with sufficient forethought and provision as to future extensions and requirements, that the general design showed a want of engineering skill and care in the utilisation of the available space, and that the electrical plant selected was not up to date in efficiency and design, that some portion of the plant would have to be replaced by more efficient machines if the undertaking was to be put on a sound basis; and, having regard to all these circumstances, he considered the undertaking was not worth £10,000. Concerning the second question referred to him, Dr. Fleming said if the Corporation either possessed or could obtain a Provisional Order he would not advise the purchase of the Company's plant on any terms, as it was not sufficiently modern or efficient, nor was it capable of the extension of which a corporation generating station should be capable; but he was somewhat reluctant to suggest that the Corporation should abandon their present idea of undertaking the supply of electricity, because that might afterwards prove to be a mistake. He had, therefore, carefully considered whether the works could be taken over on any terms, and whether they could be made self-supporting, and, if certain suggestions which he made were adopted, it would be possible to make the revenue exceed the outlay by £200 or £250, and on this basis he estimated the value of the undertaking at £7,110, to which must, of course, be added the cost of obtaining a Provisional Order (£426), or a total of £7,536. After careful consideration of the reports of the city surveyor and Dr. Fleming, the Sub-Committee have decided to offer the Company £7,500 for their undertaking. At the meeting of the City Council on Wednesday the Committee's report was discussed and adopted. It was therefore decided to offer the Company £7,500 for their undertaking, this offer being subject to the approval of the Board of Trade, and to the sanction of the Local Government Board to the borrowing of the money.

Exhibition.—An International Industrial Exhibition will be held in the Agricultural Grounds, Johannesburg (South African Republic) next year. It is to be opened in April and will last for six weeks. The charge for space has been fixed at 10s. per square foot.

Folkestone.—The electric lighting question has been before the Town Council in one form or another for the past 10 years, and matters are in precisely the same state to-day as they were when the subject was first introduced. A special meeting of the Council was held last week for the purpose of (*a*) considering reports from the Special Electric Lighting Committee, (*b*) reconsidering the report of the first Electric Lighting Committee, and (*c*) generally considering the subject of the introduction of the electric light. The report of the Special Committee recommended the adoption of a high-tension alternating-current system, with transformer substations and a low-tension three-wire network of mains for private supply. The principal thoroughfares of the town are included in the area of supply, and it is recommended that the generating station be erected near the Darlington Arch. At the start the street lighting is to be confined to the Lees, and the machinery at the station should be capable of supplying current to 4,500 8 c.p. incandescents continuously for private lighting and 22 arcs for public lighting. The cost of the plant, mains, &c., is estimated at £12,910, and working expenses at £2,936, or a total of £15,846. The probable revenue is put at £3,000 from private and £730 from public lighting, thus leaving a profit of £784. The report further recommended that steps be taken to obtain the necessary licence from the Board of Trade and the sanction of the Local Government Board to borrow a sum not exceeding £15,000 for the purpose of carrying out the scheme, and that Mr. F. H. Medhurst's services be retained to prepare the necessary plans, &c., and to generally superintend the work at a fee to be agreed upon. Mr. Baker, who moved the adoption of the report, said that applications for 3,580 private lights had already been received, and that if even these figures were taken as a basis, and proportionately reducing the working expenses, he calculated that there would be an annual profit of £248. Mr. Thompson adversely criticised the report, and advocated the adoption of the original and more extensive scheme which was prepared by Mr. Mark Parker, and was estimated to entail an initial outlay of £35,000. A long and somewhat incoherent discussion then took place, a proposal to get an independent expert to consider and report upon the rival schemes meeting with little support. The Mayor said he believed the original scheme a good one, but the public had condemned it. It was necessary that they should have the electric light in Folkestone, but he thought the supply should be undertaken by a private company, and the Council could protect themselves by obtaining a Provisional Order. Eventually the motion was lost, and the subject was adjourned *sine die*.

Halifax.—A deputation from the National Telephone Company waited upon a Committee of the Chamber of Commerce on Tuesday in reference to complaints by the Chamber as to the inconvenience arising from the present telephone service in Halifax. The general manager of the Company (Mr. W. E. L. Gaine) promised that local grievances should receive immediate attention, but as to the trunk service he said the Company were not now in a position to erect further trunk wires without the sanction of the Government, and that the Company had repeatedly suggested additions in the Halifax and in various other districts, but the Government had ignored their complaints. He suggested that the Chambers concerned should approach the Postal Authorities and bring pressure to bear upon them to concede what was desired. Mr. Gaine further stated the question of the reduction of the annual charges for the trunk lines was also a matter for the consideration of the Government.

Kalgoorlie (West Australia).—The Municipal Council have granted a concession to Mr. Phillip Hargan, acting on behalf of a syndicate of English capitalists, to light the town by electricity, the installation to be completed within 12 months.

Kettering.—The District Council have decided to appoint an electric lighting committee to consider and report upon the question of lighting the town by electricity. The committee were empowered to employ an expert at a cost not exceeding £30.

Kingstown (Ireland).—At the last meeting of the Town Commissioners it was decided to apply for a Provisional Electric Lighting Order.

Lighthouse Communication.—It is stated that the Mersey Docks and Harbour Board are about to lay a telegraph cable from Formby Light-vessel to Crosby Lighthouse.

Liverpool.—The Special Lighting Committee of the City Council have concluded a supplementary agreement with the Liverpool Electric Supply Company (Limited), whereby the operation of the contract for the purchase of the Company's undertaking is extended to December 31, 1896. This arrangement will enable the Council to present the necessary Bill to Parliament during the next session.

Llanelly.—As the District Council have decided not to proceed with their electric lighting scheme, Messrs. J. C. Howell and Co. (Limited) have approached the Council with a view to transferring to them the Llanelly Provisional Electric Lighting Order.

Manchester.—The Town Council are extending their electric light mains along the Oxford-road as far as Whitworth Park, and also in Stretford-road as far as Ardwick Green.

Mevagissey (Cornwall).—The Lighting Committee of the Parish Council have been making inquiries as to the cost of lighting the district by electricity and gas, and, as they report that the electric light would be the cheaper form of illumination, the Council have unanimously decided that, "Provided an electric light company be formed so as to admit of lighting the streets by electricity during the coming winter, this Council will offer £40 for lighting 30 lamps for 1,500 hours in the ensuing twelve months, and if any further lights be required, payment at the same rate." The Committee are to report further on the matter at the next meeting of the Council.

Montrose.—The Police Commissioners have expressed approval of the suggestion to establish telephonic communication with the Kinnaber Waterworks, but have referred the matter to the Streets and Roads Committee for the purpose of ascertaining the probable cost.

Morecambe.—Negotiations have been for some time in progress for the purchase of the plant and works of the Morecambe Electric Light and Power Company (Limited) by the Town Council. The Finance and General Purposes Committee have now decided to offer £4,125 for the undertaking. This offer is contingent upon the Council obtaining the necessary powers and authority from the Board of Trade.

Plymouth.—The borough surveyor has been commissioned to inspect the Bristol and Walsall electric tramways with a view to the introduction of electric traction on the Ebrington-street lines.

Digitized by Google

PRESS TELEGRAMS.—At Bordeaux, on Tuesday last, the Press Congress decided to appoint a committee for the purpose of securing a reduction in the present rates for international Press telegrams.

QUEENSTOWN.—The Town Commissioners and the Local Gas Company are still at loggerheads over the lighting of the town. At the last meeting of the Commissioners the Chairman once more summarised the grounds of the dispute, and added that the Commissioners were endeavouring to formulate a scheme for lighting the town by electricity. Tenders were being at present advertised for, and as soon as these were received they would push on with the matter as fast as possible.

TELEGRAPHIC COMMUNICATION IN THE CHANNEL ISLANDS.—A petition from the inhabitants of the islands of Guernsey and Sark, praying that they be put in full telegraphic communication with each other, has been presented to the Postmaster-General by the Lieutenant-Governor of Guernsey. Pending the reply of the Postmaster-General, a military heliograph system, worked from the Mill at Sark to Fort George, Guernsey, has been established.

TELEGRAPH WIRE EXPORTS.—The value of the exports of telegraph wire and apparatus of Great Britain during August amounted to £29,488, as against £67,550 in the corresponding month of last year, and £176,859 in 1893. The value of the aggregate exports during the first eight months of this year amounted to £338,169, as compared with £1,254,774 in the corresponding period of last year, and £733,359 in 1893.

THE TELEPHONE IN MEXICO.—Telephonic communication is to be established betwen Ario and La Huacana, Michoacán State.

TOTTINGTON (LANCASHIRE).—We are informed that Messrs. S. H. Heywood, Brazenose-street, Manchester, have received the contract for erecting an arc-lighting installation at the mills of Messrs. S. Knowles and Co. (Limited), printers, &c., Tottington. The work is being carried out in accordance with the plans and specifications of Mr. Walter Leake, consulting engineer, Manchester.

WINDSOR.—In reply to an inquiry at the last meeting of the Town Council as to what progress had been made with the electric lighting question, it was stated that the Electric Lighting Committee were awaiting Messrs. Medhurst and Liardet's report as to what water power would be available. The Town Clerk was instructed to write stating that the Committee were anxious to receive the report.

WOKING.—The District Council have decided to light the village and Mayford Ward by means of oil lamps. In explanation of this step the Chairman said that the Electric Light Company would only lay their mains in a small part of the district, while the Gas Company had also declined to supply gas to the district.

WORKS LIGHTING.—The premises of the Newquay Baths and Sanitary Steam Laundry Company, Plymouth, are to be lighted electrically.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

COMPANIES' MEETINGS AND REPORTS.

Brush Electrical Engineering Company (Limited).

The sixth annual report of the Directors of this Company, to be presented at the meeting to be held at Cannon-street Hotel, London, E.C., on Monday next, at 12 noon, states:—

The profit and loss account shows a gross profit of £37,858. 4s. 5d., after allowing for bad and doubtful debts to the amount of £2,205. 17s. 9d., and writing down the value of shares and debentures in other companies, as shown in the balance sheet. After deducting from the gross profit, general charges, maintenance of buildings, plant and patents, staff bonuses under the Company's profit sharing scheme, and interest on debenture stock, there remains a net balance of profit, including amount brought forward, of £11,329. 12s. 8d. An interim dividend at the rate of 6 per cent. upon the Preference shares, and 5 per cent. upon the Ordinary shares, has been already paid for the half-year ended December 31, 1894, amounting to £12,150. The net profit for the year, exclusive of the amount brought forward, is £7,541. 3s. 8d. The Preference shareholders have already received £5,400 of this sum by way of interim dividend as above, and they will be entitled to receive the balance of £2,141. 3s. 8d. before the Ordinary shareholders receive further dividends. The result of the year's operations shows a decrease of net profit as compared with last year of £19,739. 8s. 5d., which the Directors state is solely due to loss incurred during the second half of the Company's financial year in connection with the contract which the Company is carrying out for the City of London Electric Lighting Company (Limited), and arose out of differences between the two Companies as to the obligations involved under the contract. These differences are, however, now at an end, and work under the contract is being again proceeded with.

During the year the sum of £2,646. 1s. 9d. has been expended upon extensions of buildings and plant at the Loughborough Works, and new patents taken over by the Company. The Company's Austrian business

Digitized by Google

yielded improved results during the past year, and is now established upon a thoroughly profitable basis. The Australasian branch also showed a satisfactory profit for the year ended April 30th last, but, with improving commercial prospects in the Colonies, the Directors anticipate correspondingly favourable results from this branch of the Company's business. The contract and installation department has been fully employed during the past twelve months, and electricity supply stations for the Municipalities of Leicester and Worcester, and for the Dover Electricity Supply Company, have been equipped with the Company's electrical plant, and opened during the year. The works at Loughborough are at present fully employed, and sufficient work is in hand and in prospect to maintain them so for some time to come. Plant for the equipment of the St. Luke's (Middlesex) and the Wandsworth electricity supply stations for the County of London and Brush Provincial Company are in course of manufacture in the electrical shops, as is also the plant for the lighting of Valetta and the Government Works at Malta, for which the Company recently received an order. The rolling stock and car departments are engaged upon the construction of locomotives for the Beira Railway, of cars for the Rouen Electric Tramways Company, and other orders.

The Directors report that they have made arrangements for the manufacture of a new high-speed enclosed engine of a novel and simple construction, the invention of the Company's Joint Manager and Chief Engineer, Mr. J. S. Raworth. We have received copies of the reports of Prof. W. C. Unwin, F.R.S., and Mr. W. H. Maw, M.I.M.E., on this new engine.

The bonus profit-sharing scheme introduced among the Company's staff and workmen two years ago is giving general satisfaction among the employés, and the Directors are satisfied that the system is working well.

In order to provide capital to meet the large expansion of the Company's business which has taken place since the last issue of capital in 1893, the Directors have decided to make an issue of £105,000 Second Four and a-Half per Cent. Debenture Stock, which will be allotted at par to the Preference and Ordinary shareholders. The entire interest charge on the Company's debenture stock (including the £105,000 now to be issued) will then stand at £10,350 per annum, while the average annual net profit (including debenture interest) for the past six years, since the formation of the Company in 1889, amounts to £25,337, and the Directors state the stock will be amply secured.

The increase in the Company's business, especially during the past few years, is largely attributable to the development of municipal and private electricity supply from central stations, of which business the Company has been successful in securing a substantial share. The manufacture of steam engines for electrical engineering purposes has also been undertaken during that period, and upwards of 35,000 H.P. have been sold.

The Directors also state that they are giving close attention to electric traction and electric elevator work, in both of which directions an important development appears to be imminent.

The retiring Directors (Messrs. Edward Woods and A. Ayres), being eligible, offer themselves for re-election, as do the auditors (Messrs. Cooper Brothers and Co.).

NEW COMPANIES, STATUTORY RETURNS, &c.

BEST BELTING COMPANY (LIMITED).—This Company has been registered with a capital of £10,000, in £1 shares, to acquire the business of the Best Belting Company, now carried on at 13, Cullum-street, London, E.C. The first Directors are Messrs. H. Muirhead and D. Robinson.

CELLINE ART METAL WORKS (LIMITED).—This Company has been registered with a capital of £5,000, in £5 shares, to manufacture, sell and deal in art metal work in iron, steel, brass, copper, bronze, &c., chandeliers, brackets, electroliers, suspension lamps, &c., for electric light, gas and oil.

JOHNSON MINERS' SAFETY LAMP COMPANY (LIMITED).—This Company has been registered with a capital of £5,000, in £1 shares, to carry on business as manufacturers of and dealers in Johnson miners' safety lamps and similar goods.

ELECTRICAL OIL REFINING COMPANY (LIMITED).—The statutory return to August 22nd has been filed. Of a nominal capital of £5,000, in £1 shares, 2,000 have been taken up, of which 1,493 have been issued as fully paid. The full amount has been called on the remaining 507 shares.

EXCHANGE TELEGRAPH COMPANY (LIMITED).—The annual return to August 14th has been filed. The nominal capital is £246,250, in 8,125 "A" and 16,500 "B" shares of £10 each. All the "A" and 16,200 of the "B" shares have been taken up, and the latter have been issued as fully paid. 2,125 "A" have been issued with £8 per share considered as paid, and £1 additional per share has been called, while £9 per share has been called on the remaining 6,000 "A" shares; £816 has been paid on 102 forfeited shares.

EXETER ELECTRIC LIGHT COMPANY (LIMITED).—The annual return to August 30th has been filed. The nominal capital is £20,000, in 1,500 Ordinary and 500 "A" or £6 per Cent. Preference shares of £10 each; 305 of the former have been issued as fully paid, and the full amount has been called on 820 Ordinary and 75 Preference shares. Negotiations are now in progress for the purchase of this Company's undertaking by the City Council.

GALLOWAYS (LIMITED).—An agreement has been made with the old Company and J. W. Pollitt, Marsden-street, Manchester (its liquidator), for the purchase of the business of the old Company for the sum of £109,170. 3s. 11d. in cash and the allotment of 1,500 fully-paid shares of £100 each in the new Company. This is in addition to an issue of £10,000 debentures secured upon the property of the old concern, which will be transferred to the present undertaking.

GLOBE TELEGRAPH AND TRUST (LIMITED).—The annual return to August 9th has been filed. Of a nominal capital of £5,000,000, in 250,000 Preference and a like number of Ordinary shares of £10 each, 180,042 of the former and 180,227 of the latter have been allotted, and the full amount has been called in each case.

HOBART ELECTRIC TRAMWAY COMPANY (LIMITED).—The annual return to June 25th has been filed. The nominal capital is £105,000, in £1 shares, and 45,000 of these have been taken up; 20,000 of these have been issued as fully paid, and the full amount has been paid on the remaining 25,000 shares.

F. H. ROYCE AND CO. (LIMITED).—The annual return to June 13th has been filed. Out of a nominal capital of £30,500, in 30,000 Ordinary and 500 Deferred shares of £1 each, 14,603 of the former and all the latter have been taken up, and 12,514 of these have been issued as fully paid. The full amount has been called on the remainder.

CITY NOTES.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver, 30½d. per oz. (Sept. 19th). Consols (2¾ per cent.) 107½—107⅝ for money, 107$\frac{11}{16}$—107$\frac{13}{16}$ for account (Sept. 19th); 2½ per cent. 106—106¼. Stock Exchange Settling Days: Consols, Oct. 1st; Stocks and Shares Continuation Day, Sept. 25th; Ticket Day, Sept. 26th; Pay Day, Sept. 27th; Mining Shares Carry-over Day, Sept. 24th.

SIR W. G. ARMSTRONG, MITCHELL AND CO. (LIMITED).—The Directors of this Company propose to pay a balance dividend of 9½ per cent., making a total distribution of 11¾ per cent. for the year ended June 30th, carrying forward a balance of £2,285.

BELL'S ASBESTOS COMPANY (LIMITED).—An extraordinary general meeting of the shareholders of this Company was held at the Cannon-street Hotel last week, when it was resolved to divide the present shares of £5 each into five shares of £1 each. Further resolutions approving the draft of the new regulations were also passed.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended September 15th were £808, against £826 in the corresponding week of 1894, a decrease of £18. The total receipts for the half-year amount to £9,316, against £9,402 for the corresponding period of 1894, a decrease of £86.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have decided to pay, in addition to the dividend at the rate of 10 per cent. per annum on the Preference shares, an interim dividend at the rate of 4 per cent., free of income tax, on the Ordinary shares, both for the half-year ended June 30th last.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company announce the payment on October 15th next of interest of 3s. per share, less income tax, being at the rate of 6 per cent. per annum on the Preference shares for the quarter ending September 30th, and the usual interim dividend of 2s. 6d. per share on the Ordinary shares, free of income tax, in respect of profits for the quarter ended June 30th. The transfer register will be closed from October 8th to 15th inclusive.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 15th inst. amounted to £1,278. The amount for the corresponding week last year was £1,084; increase, £194.

ROCKHAMPTON (QUEENSLAND) GAS AND COKE COMPANY (LIMITED). The report of the Directors of this Company for the half-year ended June 30th last states that the profits on the electric lighting branch of their business amounted to £303. 13s. 9d., out of which £300 was paid as interest upon the whole of the Company's debentures. The Directors erected additional plant and buildings during the period under review, and they have appointed Mr. E. F. J. Hewlett, electrical engineer to the Company. Dividends of 7 per cent. per annum on the Ordinary shares, and 9 per cent. per annum on the Preference shares were declared.

ROYAL ELECTRIC COMPANY OF MONTREAL (LIMITED).—The coupons due October 1st next on this Company's Four and a-Half per Cent. Debenture Loan of £120,000 will be paid on and after that date by the Bank of Montreal, 22, Abchurch-lane, London, E.C. Coupons must be left three clear days for examination.

SCOTTISH HOUSE-TO-HOUSE ELECTRICITY COMPANY (LIMITED).—The transfer books of this Company will be closed from 19th inst. to the 30th inst. inclusive.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended September 13th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,725.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the half-month ended September 15th are £1,441, as compared with £1,664 in the corresponding period of 1894. The May receipts, estimated at £5,394, realised £5,449.

WESTRALIA (LIMITED).—At the general meeting of the shareholders on Monday, the Chairman (Mr. P. Tibbs) said they had acquired a concession for 21 years for the supply of electric current for lighting and power purposes to the Municipality of Coolgardie, which concession they had sold to the West Australian Electric Lighting and Supply Company (Limited), a company recently formed with a capital of £80,000, and of this sum £35,000 would be working capital. Operations in the terms of the concession had been already begun, and he thought it a matter for congratulation that so young a company should have been privileged to confer on the centre of the mining industry of West Australia the immense advantage of the latest mode of lighting which science had invented, in substitution for the primitive method of illumination at present employed.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 906. [No. 22. Vol. XXXV.] FRIDAY, SEPTEMBER 27, 1895. PRICE SIXPENCE.

NOTES.

THE recent peremptory notice of the Electricity and Public Lighting Department of the St. Pancras Vestry anent a 220-volt supply was calculated to cause a considerable flutter in certain electrical dovecots, and it did do so. Below we reprint the circular as originally issued:—

VESTRY OF ST. PANCRAS.

NOTICE TO ELECTRICAL ENGINEERS AND CONTRACTORS.

NOTICE IS HEREBY GIVEN that on and from the 1st September, 1895, the supply to consumers' premises will be delivered at 220 volts, and that no single circuit will be permitted to carry more than 20 amperes.

ALBERT E. PYCRAFT, Chief Clerk.

Electricity and Public Lighting Department, Vestry Hall,
Pancras-road, London, N.W.
Dated this First day of September, 1895.

IT was not unnaturally concluded from this document that 220-volt lamps and corresponding wiring and fittings would be in immediate and immense demand in the district served by the Stanhope-street station. So much the better for trade, said the short-sighted shrewd ones. Others, looking a little more at the general principle of the thing, doubted whether the obvious reading of the ukase was the one intended; and, if it were, doubted still more the legality and expediency of the step contemplated.

AN emended edition of the circular, however, makes it clear that it applies only to *future* customers, so that we may assume that Mr. BAYNES intends, as at Bradford, to connect all additions to the present three-wire network across the outers, and to run all extension feeders at 440 volts.

MR. BAYNES is quite justified in assuming, in his letter to *The Times* of Wednesday, replying to that of Messrs. HANDCOCK and DYKES, which appeared in Saturday's issue, that "those who best understand the subject and its importance on the future of electric lighting are the most desirous of co-operating to render the movement I have introduced thoroughly popular and successful," and as in a matter of this kind the proof of the pudding is most certainly in the eating, *he* is further justified in regarding his Bradford experience as a conclusive answer to all croakers. At the same time the circular was worded so as to cause a maximum of alarm among consumers, and knowing what we do of average electric light fittings and wiring, we cannot consider the fear lest 220 volts may prove too much for them an altogether vain imagining. However, there is, as we understand it, no question, at any rate at present, of putting this matter to the test at St. Pancras. Due warning having been given, there need be no trouble about 220-volt fittings. Mr. BAYNES dismisses the important 8 c.p. 220-volt lamp question by stating that such lamps are on the market. We do not doubt it. The point is, are they reliable? All electrical engineers will wish well to Mr. BAYNES in his 220-volt crusade, and must hope that he will carry it through with the minimum of mishaps and the least possible inconvenience to customers and to the trade.

SANDWICHED between a phenomenally successful meeting at Oxford and a probably large and busy meeting at Liverpool next year, the meeting of the British Association at Ipswich would have been able to find reasonable excuse for weakness and failure had any been manifest. Ipswich has little claim to be considered a centre of scientific interest; it is quite a small town, and the accommodation it had to afford could not rank beside that at any one meeting during the past three or four years or the next two. Yet, in the opinion of many British Association veterans—those who have long been seen in the reception rooms from year to year—the Ipswich meeting certainly has not fallen below the average in quality, and in some sections it has risen above it. In the matter of genuinely novel interest, the palm must be yielded to the Anthropological Section, presided over by the famous Egyptologist, Mr. FLINDERS PETRIE; but though neither Section A, B, nor G produced anything comparable with last year's startling announcement of the discovery of argon, yet there has been for each of these a daily portion of interesting and useful work. It is not for the dramatic announcement of startling discoveries, whether of comets, planets, ancient races, or new elements, that the British Association exists; but it is that all sorts and conditions of scientists may meet together and "rub each other's angles down."

PROBABLY the hardest worked Section is that designated by A, which is devoted to mathematics and physics; and it is a common occurrence, on days when other Sections are out at play, for this branch of the Association to divide itself into two or even three sub-sections, each with its own lengthy programme of Papers. We are glad to hear there is some idea among those who have the control of such things, of permanently lightening the load on A, by the creation of a

Digitized by Google

distinct Electrical Section, which should absorb into itself all that is electro-technical in A, B and G. We sincerely hope this proposed new Section may be created; and the earlier it comes into existence, the better will it be for those for whom the chief attractions of the Association are electrical. It is a comfort to find this proposal emanating—albeit unofficially—from within the Association itself; for we had not dared to make the suggestion ourselves, for fear of being told that electricity was only a branch, indeed a mere sprig, of physics. Under the existing arrangements there is necessity for a high-frequency alternating pilgrimage between A and G, the dissipated energy in which is only slightly reduced by the institution of "electrical day" in the latter Section. When the amplitude of the oscillations between A and G is large the energy wasted, heat generated, &c., are enormous; and we sincerely hope and with all humility suggest that, at Liverpool, if the new Electrical Section has not there come into existence, the *loci* of A and G shall be made as nearly to coincide as the properties of three-dimensional space will permit.

A VERY useful task has been imposed, by Section G, on a newly-formed Screw Standards Committee, as the result of the representation made by Mr. R. E. CROMPTON in regard to the want of uniformity of the so-called B. A. screw gauges. This task is no other than to complete the work of the Screw Standards Committee which was formed some ten years ago, the practical outcome of which was the standardisation of a set of small screw threads, such as are used in electrical and other scientific instruments. What remains for the newly-created Committee to do is to set these standards upon the same workable basis as is the case with the larger gauges covered by the Whitworth standards. To so great a pitch of perfection has the standardised manufacture of Whitworth taps, stocks and dies, &c., been carried, that it could only be due to very careless handling of the tools if a bolt made on the Clyde were found not to fit a corresponding nut made, say, in Swansea. But, alas! 'tis not so with B. A. screws. The first to call recent attention to this matter was Mr. ELPHINSTONE, in his letter which we published on August 9th (*The Electrician*, August 9th, p. 497). But we believe that it had been even then Mr. CROMPTON's intention to call attention to the matter, at the Ipswich meeting of the British Association. He has done so, and we hope to good purpose.

AT a meeting of Section G of the British Association, when one who took part in the discussion on Mr. PHILIP DAWSON's Paper on electric traction proposed that our metropolitan underground railway should be worked electrically, Prof. VERNON HARCOURT replied that the insuperable obstacle to the proposed improvement lay in the fact that steam and electrically-propelled trains could not run over the same lines. There is, however, no insuperable obstacle about the matter at all, as is proved by the recent partial conversion of the Kentucky and Indiana Bridge Company's railway into an electric overhead trolley system, both steam and trolley cars running over the same rails. Whatever difficulty there may be in propelling the Circle trains electrically, certainly does not arise from the fact of the Inner Circle being used by trains from many of the main lines running into London

THE ingenious method of delineating alternate-curren wave-forms described before Section A by Mr. JAMES MARK BARR and his two coadjutors, is one of those things about which everyone who has been working at this particular problem will probably exclaim, "Why ever didn't I hit on this idea myself!" By making the contact brush revolve as well as the contact disc one is able, by means of a reflecting galvanometer and a piece of sensitised paper, to secure an exact and permanent trace of the wave-form, and this at a manageable frequency, without interfering with the normal speed of the machine under test.

WE were among the first to compliment the late Postmaster-General upon his granting the Committee of Inquiry into the alleged grievances of the postal and telegraph employees, and upon the constitution of that Committee; we regret the more, therefore, to find fault with the course he subsequently adopted in virtually anticipating their verdict in his Annual Report, which is just to hand. The publication of a defence of the Department against the complaints of its servants is, we believe, a quite unusual course; and to do so while an inquiry into the matter is still proceeding is at once superfluous and unfair. Still worse, the defence, such as it is, though it explains a good deal, is no defence at all, for it never touches the question at issue, namely, whether the men have grievances or not. It is very sad, no doubt, that expenditure outstrips revenue; but this is not peculiar to the Post-Office; and to try to close the mouths of the disaffected by telling them that there are hundreds of aspiring Board School candidates ready to take their places is only adding fuel to the flame. When Mr. ARNOLD MORLEY retired from office the vacancy was not knocked down to the lowest bidder. Probably his Report was penned before that catastrophe occurred.

SOME particulars which we publish to-day from the columns of the New York *Electrical Engineer* relating to the growth and prospects of long-distance telephony are of special interest to this country just now, where a system of trunk lines for telephonic purposes is being inaugurated upon an extended scale and under Post Office control. We cannot adopt all the deductions which our contemporary draws from the statistics it is able to furnish with regard to the relative use of the telephone and the telegraph; still less can we admit that there is any likelihood of the former displacing the latter to any serious degree in popular favour in countries like England and America. Nevertheless, it may be admitted that for a considerable number of commercial requirements the telephone is a rival which the telegraph cannot afford to despise. That this fact was realised so long ago as 1879 by the Western Union Telegraph Company, who demanded and obtained 20 per cent. of the earnings of the Bell Telephone Company as a consideration for not entering into litigious opposition to the then new-born competitor, speaks well for the foresight and business capacity of the older Company. And that its young competitor has gone on prospering in spite of this heavy burden upon its profits is a very complete justification from the business point of view of the corresponding tax placed upon telephone operations

Digitized by Google

by the Post Office in this country. The commission under this head paid to the Western Union Telegraph Company already amounts to nearly one and a-half million sterling; a corresponding commission paid to the Post Office, with an unquestionable monopoly, which the American Telegraph Company never possessed, is, therefore, not the extortionate imposition that it has been sometimes represented to be.

We have said that we do not implicitly accept the deductions of our electrical contemporary; and the more we look at the figures the less able are we to accept its conclusions. That there are ten times more telephonic messages than there are telegraphic messages is an interesting fact for the telephone companies, but as most of the former are urban communications of the speaking-tube order we are still left in complete ignorance as to the probable proportions of inter-urban or long-distance messages that are or will be transmitted by telephone when that system is developed to its utmost limits. It seems to us that its employment will, in a manufacturing country where *la petite culture* is almost unknown, always be confined mainly to commercial transactions of a very specia character, and that for general purposes the telegraph must always continue to be the chief means of communication. The difference between them is very like that between a personal interview by appointment and the despatch of letters through the post. The telegraph has not reduced the business of Her Majesty's mails, and we do not believe that long-distance telephony will materially diminish the business done on long-distance telegraph wires.

Stafford.—The Stafford municipal three-wire system comes into operation this week.

Cable Interruptions :—

	Date of Interruption.
Aden-Zanzibar	September 2, 1895.
Cadiz-Teneriffe	September 25, 1895.

Institution of Junior Engineers.—There will be a meeting of this Institution on Friday, October 4th, 8 p.m., at the Westminster Palace Hotel. Annual general meeting to receive the Council's report, elect officers for ensuing session, &c.

Masts for Electric Tramways.—The Mannesmann Tube Company is now producing electric light and tramway masts by their seamless process. The masts for the overhead conductor electric tramways at Stuttgart and at Pankow were supplied by the Mannesmann Company.

Train Lighting.—A successful experiment in train electric lighting was carried out this week by the Great Northern Railway Company of Ireland. A train ran from Dublin to Drogheda and back. The main feature is that each vehicle is provided with its own dynamo, axle-driven, and accumulators to light the lamps when the train is standing.

Exeter.—The Exeter Electric Lighting Company, which has unfortunately got into financial difficulties, recently offered its plant and business to the Corporation for the sum of £10,000. The Corporation, after a lengthy debate, agreed to pay £7,500, and this sum has now been accepted by the Company.

Electric Traction in Bergen.—The town of Bergen, in Norway, will soon be possessed of electric trams, in which respect Scandinavian towns are somewhat behind the times. A company has been formed, with a capital of about Lr.50,000, and the construction of the trams has been entrusted to the Union Electric Company of Berlin.

Monuments and Memorial Tablets.—A memorial tablet in honour of Prof. Helmholtz has been affixed to the house, No. 8, Haditzstrasse, at Potsdam, where he was born, and it is stated, says *Nature*, that it is intended to erect a joint monument to the memory of Werner Siemens and Helmholtz in front of the Technische Hochschule at Charlottenburg.

Leipzic Electric Supply Station.—On August 28th this station commenced regular supply for the public and private lighting of the town. There are so far 46 15-ampere street lamps and 5,000 glow lamps connected, but as the lamps in view already exceed 30,000 16 c.p. lights, the electric plant just put down will very soon have its full load.

Obituary.—Mr. Paul Prince, the head of the signalling department of the Midland Railway, died on Monday, from cancer in the throat at the age of 45.——The death took place, on Tuesday, of Mr. John R. Edwards, superintendent engineer for the North Wales district of the Post Office telegraph system. Previous to 1870 Mr. Edwards was in the service of one of the telegraph companies. The deceased was 58 years of age.

Shock from High-Pressure Mains.—A lineman in the employment of the Rochester Gas and Electric Company of America received a shock from a live wire on August 28th, and was apparently dead for some six minutes, when he recovered consciousness, after being subjected to the d'Arsonval treatment. His right hand and wrist were badly burned, but he was otherwise uninjured. The wire he came in contact with carried 1,600 volts, and it is reported that he received the full voltage by short-circuiting the line with his body.

Electricity in the Navy.—Some few years ago the fine second-class battleship "Barfleur" was fitted with electric motors in connection with the training and elevating gear of her big guns. Experience of the use of electric motors for this purpose has proved so satisfactory that the Admiralty have now, in addition, ordered electric gear for the ammunition hoists of the battleships "Centurion" and "Renown." The 12in. guns on board the first-class battleships "Cæsar" and "Illustrious" are also to be fitted with electrically-driven training and elevating gear.

Electric Railways in Michigan.—The Detroit, Port Huron and St. Clair River Railway Company has, according to the *Electric Railway Gazette* of New York, been formed to construct an electric line which it is announced will be ultimately 65 miles in length. The proposed line is projected for the purpose of giving transportation in the territory east of the Grand Trunk road from Detroit to Port Huron, thus affording communication with numerous St. Clair lake and river towns now without railway communication. The project is an old one, but in its revived form electricity is proposed as the motive power for the road.

British Association Grants.—The following is a list of the grants of money appropriated to electrical and allied purposes by the General Committee of the British Association at Ipswich:—Prof. Carey Foster—Electrical Standards (and unexpended balance in hand), £5; Lord Rayleigh—Mathematical Tables (unexpended balance); Dr. E. Atkinson—Abstracts of Physical Papers, £100; Prof. S. P. Thompson—Uniformity of Size of Pages of Transactions, &c. (renewed), £5; Sir H. E. Roscoe—Wave-length Tables of the Spectra of the Elements, £10; Prof. J. E. Reynolds—Electrolytic Quantitative Analysis (renewed), £10; Prof. A. B. W. Kennedy—Calibration and Comparison of Measuring Instruments (£25 renewed), £30; Mr. W. H. Preece—Introduction of the B.A. Small Screw Gauge, £10.

Steam v. Electric Lines in America.—There exists between the towns of St. Paul and Minneapolis two steam railways and one electric railway, and it is interesting to note the effect the latter has had upon the suburban business of the former. The distance between the two towns is about 10 miles, and is practically the same on all lines. The two steam lines were running trains every half-hour, the single fare being 30 cents and the return fare 50 cents, and the time taken for the single journey was 25 minutes. Against this the electric cars run at six-minutes intervals through the streets of both towns, and stop at any corner. The fare is 10 cents for the whole journey, and the time occupied is 50 minutes. The electric line now takes the bulk of the business, with the result that a large proportion of the suburban trains upon the steam lines have been taken off.

Electric Railway Patent Litigations in America.—The Siemens and Halske Electric Company of America have brought

Digitized by Google

an action against the Metropolitan Elevated Railroad at Chicago, alleging that the latter is infringing their third-rail patent granted to Dr. Werner von Siemens in the United States on August 11, 1885, covering the system now in use on the Metropolitan road. The General Electric Company of New York is, of course, the real infringer, and the defence is in its hands. The same Company also brought, on September 5th, a suit against the Baltimore and Ohio Railroad Company, in the United States Circuit Court, District of Maryland, for infringement of a patent granted to Ernst Werner von Siemens on an "Improvement in electric railways." "We understand," says *Electricity* of New York, "that the overhead trolley device used in the Baltimore tunnel is identical with the device described in the Siemens patent."

Proposal to Increase the Demand for Electric Light in Glasgow.—The Glasgow Corporation Sub-Committee on Electric Lighting recently appointed six of their number as a special Sub-Committee to consider and report as to what steps, if any, should be adopted with the view of increasing the demand for electric current. A feeling is growing in Glasgow to the effect that it will be difficult for the electric light, at 6d. per Board of Trade unit, to compete successfully against Corporation gas of excellent quality at 2s. 4d. per 1,000 cubic ft., and with no charge in the shape of meter hire, while in the former case a charge is made for the use of the electric meter. There is also the fact that the consumption of gas by Welsbach incandescent burners is rapidly extending, many people having got the notion into their heads that gas lighting by the incandescent method is practically equal to incandescent electric lighting and much less costly.

New Books.—Prof. Silvanus Thompson has completed the fifth edition of his work on "Dynamo-Electric Machinery," the last edition of which was published in 1892. It will be issued about the end of October, by Messrs. Spon, simultaneously in New York and London. A good deal of old matter has been excised in the process of revision, mainly in the earlier part of the book, to make room for recent developments, particularly in alternate-current work. The number of cuts has been increased to 520, and the lithographed plates have been revised, 12 of those in the new edition being new. Several of the chapters have been entirely rewritten, those on synchronous alternate motors, on asynchronous alternate motors, and on transformers being new.——The Cambridge University Press announce that a book by Prof. J. J. Thomson, entitled "Elements of the Mathematical Theory of Electricity and Magnetism," will be ready very shortly. Price 10s.

Telegraph Revenue and Expenditure.—The following table, taken from the Postmaster-General's Annual Report, shows the revenue and total cost of the telegraph service, taking into account the interest on capital expenditure for each of the last seven years. The deficiency for the past year was £452,803.

Year.	Receipts plus nominal value of work done for other Departments.	Expenditure.			Annual interest on capital.	Deficit.
		Charged to Telegraph vote.	Charg'd to votes of other Departments	Total.		
1888-89	£2,129,965	£1,969,324	£72,037	£2,041,361	£353,787	£265,183
1889-90	2,364,099	2,179,921	99,065	2,278,986	306,016	197,690
1890-91	2,456,764	2,265,338	123,243	2,388,581	299,215	231,032
1891-92	2,545,612	2,507,012	124,883	2,635,895	298,883	389,166
1892-93	2,528,312	2,567,019	125,975	2,692,994	298,888	465,570
1893-94	2,579,206	2,641,020	116,625	2,757,645	298,888	477,327
1894-95	2,646,414	2,675,339	124,990	2,800,329	298,888	452,803

Finsbury Technical College.—The evening classes at the Technical College, Finsbury, will recommence on Monday next, the 30th inst., when the introductory lecture of the advanced course on Electrotechnics (Lighting and Power) will be given by Prof. S. P. Thompson on "Rotating Magnetic Fields." The subsequent lectures of this course will be taken by Mr. O'Keeffe and by Prof. Thompson, who will take up special topics, such as electric meters, design of alternate-current machinery, &c. The Wednesday evening course, by Prof. Thompson and Mr. E. Thomas, will deal with the current, its measurement, and its application to the electro-magnet, &c. There will be the usual practical classes in the laboratories, and Mr. E. Rousseau will later take up a laboratory class on electrotyping and electroplating. In the department of Mechanical Engineering Prof. Perry will give, in addition to the ordinary course on Practical Mechanics, a short special course on Thermo-dynamics as applied in Engineering, on Thursday evenings.

The American Bell Telephone Company and The Western Union Telegraph Company.—In its issue of August 28th the *Electrical Engineer* of New York publishes *in extenso* the famous agreement entered into in 1879 between The American Bell Telephone Company and The Western Union Telegraph Company, by which the former agreed to pay the latter a royalty of 20 per cent. on its gross receipts, and the latter agreed to abandon its existing exchanges and abstain from all telephone business. This agreement nominally terminates in November, 1896. Owing to the growth of telephony, especially of the long-distance order, it is thought in America that the Western Union Company has, so to speak, sold its birthright for a mess of pottage; a truly regal mess of pottage, however, since the sums paid over to the Western Union Telegraph Company during the last 15 years by the Bell Telephone Company under the agreement of 1879 amount to something like £1,500,000. There are many indications, says the *Electrical Engineer* of New York, "that the habit of telegraphing does not gain ground, while the practice of telephonic intercourse grows at an extravagant rate." The average is one telegraph message per year per head, and appears to be steady; in the cities it now falls below that, showing the limiting effect of the telephone assisted by district messengers.

A Curious Lightning Fatality.—On Tuesday, August 6th, during the meeting of the National Artillery Association at Shoeburyness, a somewhat curious lightning-stroke fatality occurred. At 6.50 p.m. Charles Howse was walking along a footpath leading from South Shoebury to Shoeburyness Railway Station, when he was struck by lightning and instantly killed. The footpath is 6ft. wide, having on one side a shallow ditch and a row of tall elm trees and on the other an iron railing about 5ft. high, the rails forming a row of pointed spikes projecting 6 inches above the top bar. There had been no rain for three-quarters of an hour previously. The unfortunate man was struck on the left side of the head and slightly burnt about the body, and some of his clothing was considerably torn. As the deceased had on his person, in addition to some 14s. in silver, no less than 37 sovereigns and 28 half sovereigns, many of which showed signs of fusion, it is possible that this mass of metal had something to do with the direction of the stroke. The silver was in the right pocket of the man's trousers, which were there blown to shreds and the money scattered in all directions. The gold, the separate pieces of which were wrapped in paper, was done up in a purse and tied up in a handkerchief, and placed in the left-hand inside pocket of the man's coat. The discharge apparently struck the man on the left of the central line of the body and left him on the right.

Mr. E. H. Griffiths on a Standard of Heat Measurement.—At the recent meeting of the British Association, at Ipswich, Mr. E. H. Griffiths brought forward the matter of a scientific unit of heat. Mr. Griffiths' experience with water, melting ice, &c., has led him to distrust that compound generally known as H_2O, and to put greater faith in melting silver and other temperature standards. He said that since the year 1879, when Rowland published his monumental work on the mechanical equivalent of heat, there could be little doubt that Regnault's expression for the capacity of heat (at all events at temperatures below 30deg.) could not be regarded as trustworthy. The author's object was to show how vague and uncertain was present knowledge of the changes in the capacity for heat of water, as its temperature varied. He was guided by one general principle—viz., that, however admirable the methods of experiment, or however sound the theories on which they were based, the numerical results were useless unless the observer had devoted sufficient attention to the measurement of the temperature. The second portion of the Paper was in relation to the consideration of certain thermal units other than those dependent on the capacity for heat of water. The third part consisted of practical suggestions, and the author laid it down that the

Digitized by Google

ideal thermal unit should be a rational, and not an arbitrary one, and have some real relation with other units of energy. Moreover, it should not be dependent on the observations or conclusions of any one investigator. Any such dependence must certainly result in further corrections and changes. It should also be of convenient magnitude, and cause as little disturbance as possible in the numerical values resulting from the present system of thermal measurements. In conclusion, the author expressed the opinion that further individual effort would avail but little. What was necessary, in his opinion, was the decision of some body having authority whose conclusions would command the respect of the scientific world.

The Retirement of Professors.—The Report of the Committee appointed by the Treasury to consider the question of the desirability of a fixed age for the compulsory retirement of professors serving under the Crown has been published as a Parliamentary paper. The Committee consisted of Lord Playfair, Lord Welby, and the Home Secretary. The following is a *précis* of the Report:—

"Presidents and professors are appointed at a maturer age, and have, by the nature of their employment at seats of learning, less tendency than Civil servants to become inefficient at the age of 65. Indeed, up to that age it is often found that their efficiency increases, by experience in teaching, as their age progresses, though undoubtedly a time does arrive when advancing age weakens the receptivity of the professor to new discoveries in science, and diminishes the inclination to alter his instruction in order to adapt it to these changes. When this occurs the students are the sufferers. Under these circumstances, we are of opinion that there should be fixed rules as to superannuation of presidents and professors, and that they should be made by college statutes and not by an Order in Council. We are of opinion that when a professor reaches 65 years of age the president of the college should be bound to report to the Government the condition and efficiency of the teaching. If these are and continue to be satisfactory, the professor need not be superannuated till 70, but at this age his retirement should be absolute. In regard to presidents, we are of opinion that the age of 70 should be the period of retirement, but there should be power to continue him as president for a certain number of years not exceeding five. We are quite aware that there are cases where professors at 70 and presidents at 75 are fully competent to discharge their duties, but the advantages derived from superannuation would be seriously diminished if, to meet these rare cases, there were uncertainty in regard to the application of a general rule."

The Postmaster-General's Annual Report.—During the year ended April 1, 1895, telegraph offices have increased by 451, bringing up the total to 9,661. The number of telegrams of all kinds forwarded in the United Kingdom amounted to 71,589,064, an increase over the previous year of 689,566. The total value of inland telegrams at the sixpenny rate was £1,880,206, as against £1,851,335 for 1894, the average payment for each message being 7·66d. Foreign telegrams numbered 5,937,715, an increase of 255,890 over the preceding year's total. Press telegrams show a slight decrease, their numbers, however, reaching the magnificent total of 5,401,783, transmitted at rates which are known to be unprofitable. A still more gratifying decrease of worthless traffic is that of free railway telegrams; and arrangements have now been made with nearly all the great railway companies for a further diminution. There has been an increase of 259,832 in the number of metropolitan local messages, an interesting fact considered in relation to the keen competition of the telephone for this class of work. Telegraph withdrawals from the savings bank during the first three months of this year numbered 18,602, an increase of 150 per cent. over the corresponding period last year. Money orders transmitted by the same medium during the whole year increased by 25,567 over the previous year, the respective numbers being 132,457, against 106,890. Nineteen additional shore lighthouses and lighthouse stations were connected by telegraph during the year; and cables were laid connecting the Hasborough and Shipwash lightvessels, and to the lighthouse on the Tasker rock. Other works of a similar kind are in hand. The erection of the new trunk telephone wires provided for by the Act of 1892 has been completed between Plymouth, Exeter, Bristol and the ports of South Wales with Birmingham, Leeds and Newcastle-on-Tyne; and those connecting London with Nottingham, Sheffield, Leeds, Manchester, Liverpool, Glasgow, Edinburgh, Belfast and Dublin, as well as separate lines between Leeds and Hull, Nottingham, Derby and Leicester; London and Chelmsford, Colchester and Ipswich; and London and Brighton. Some of these lines have been opened for traffic.

"Trolley" Excursions.—The Brooklyn Heights Railroad Company, says the *Western Electrician* in a recent issue, gave its first "illuminated trolley excursion" on Wednesday evening. The cars were beautiful in bunting and coloured electric lights. City Hall-square was alive with people to see the start of the six cars at eight o'clock, and the excursion went through crowded streets all the way from the City Hall through Court-street to Hamilton-avenue, to Third-avenue, and thence along to Bay Ridge, Thirteenth and Twenty-fifth avenues to Ulmer Park. Each car carried 175 lights. The cars were those ordinarily used on the Second-avenue line, and differ from the Company's other rolling stock only in their length. Along the top of the cars over the ventilator spaces was a row of red, amber and green incandescent lamps; below, on the edge of the roof, was another row of lights, and still further down on the uprights another string. Around the front of the roof were rows of red, white and blue lights. Under the roof over the motorman's head were rows of the same colour. On the dashboard a half-moon-shaped frame held coloured lights set close together, and in the centre of this device was a white disc with five lights in a cluster. The fronts and rears of the cars were similarly decorated. The fenders were wound about with bunting. Behind the motorman was draped a flag, and bunting was used along the tops of the cars inside and out with beautiful effect. The trolley poles and ropes were decorated with small flags. When the cars moved off they looked like miniature ferryboats on wheels, only far prettier. The trip to Ulmer Park was made without accident or incident to mar the pleasure of a large party of prominent persons who were the guests of the Company. At the park the Company's guests were seated at reserved tables, and refreshments were served. On the return trip the cars reached the City Hall at 11:30 p.m. President Rossiter and Secretary Williams, of the Company, looked after the comfort of their guests. Six cars were run, each having a seating capacity of 60 people.

Long-Distance Telephony in the United States.—In its issue of August 28th the *Electrical Engineer* of New York publishes a map showing the long-distance telephone lines now in operation in the United States, and also a short article giving some facts and figures connected with the growth of this branch of telephony. According to the last report of the Chairman of the American Bell Telephone Company, the total sum invested in telephone property in the United States amounts to £14,500,000 sterling. It would appear that no less than one-tenth of this large sum is represented by long-distance telephone investments. The long-distance work is carried out by the American Telephone and Telegraph Company, the gross earnings of which for 1894 amounted to over £200,000, an increase of nearly 13½ per cent, on those of 1893. The first inter-urban wire was constructed in 1885 between New York and Philadelphia. The system now includes 55,000 miles of line and 265,000 miles of wire, all of the very latest and best type of construction. Between such cities as New York, Boston and Philadelphia there are as many as 40 wires to the line. The standard wire employed has been 0·104 inches diameter, hard-drawn copper 5·2 ohms to the mile, supported on poles 40ft. high and 130ft. apart. According to the writer of the article in our New York contemporary, the talking is everywhere remarkably clear, and the author has frequently conversed with New York from parts as remote as Chicago and Milwaukee and obtained perfect results, even in the wet months of October and November. It will be remembered, moreover, as one of the incidents of the memorable blizzard of 1889, that the only practical exchange of news between New York and points outside was by means of the long-distance wires, and that while *telegrams* between New York and Boston were sent *viâ* Ireland over the Atlantic cable, people in New York and Boston offices were quietly chatting over the telephone as if nothing had happened. It is admitted that the present rates are high, but it is contended that good value is obtained for the money. During the day a five-minutes talk between New York and Chicago costs £1. 16s., and half that amount during the night. It is asserted in the States that the growing use of long-distance telephony is seriously affecting long-distance railway traffic and interfering with the prosperity of hotels in the large commercial towns.

THE MAGNETIC FIELD OF A RECTANGULAR CURRENT.

BY PROF. G. M. MINCHIN, M.A., F.R.S.

In a previous Paper (see *The Electrician*, September 6th), has been given a simple expression for the magnetic force-intensity at any point in the plane of a rectangular current, together with a graphic construction which enables us to calculate with ease the value of the force-intensity at all points in the plane. The object of the present Paper is to show that this graphic rule, and the expression on which it is founded, hold even for points infinitely close to the sides of the rectangle. An extension of the result to the case of a rectangular coil will also be made.

To show that the result (5) (see *The Electrician*, September 6th) holds for points very close to the sides of the rectangle, let us revert to a few elementary facts.

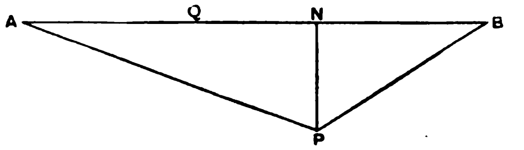

Fig. 1.

Supposing a current of strength i to flow in the *right line* B A (Fig. 1) while a unit pole is at any point P, the force exerted at P by an element of length ds of the current at any point Q is

$$\frac{i\,ds}{r^2}\sin\theta, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where $r = \mathrm{PQ}$ and $\theta = \angle \mathrm{BQP}$. Now if the perpendicular P N from P on B A is denoted by p, a simple integration of the expression (1) gives the total force at P equal to

$$i \cdot \frac{\cos \mathrm{A} + \cos \mathrm{B}}{p}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where A and B denote the angles B A P and A B P respectively.

If the line B A is so long with respect to p that A and B are practically zero, this becomes $\frac{2i}{p}$; and if P is infinitely near A B, this expression for the force becomes infinite.

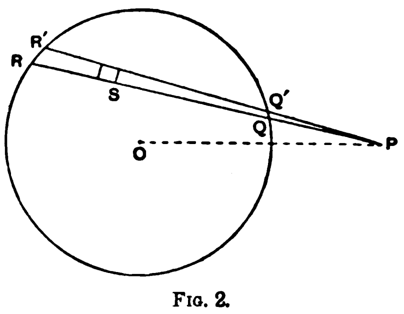

Fig. 2.

We know, of course, that even when P is on A B, the force is *not* infinite, so that the mathematical expression appears to be erroneous. But observe that if A B is a *wire*, and not a mere Euclidian line, the diameter of its cross-section must be taken account of when P is near its surface, and that in order that (2) should be applicable in the calculation, we must break up the wire into an infinitely great number of infinitely thin filaments, each of which conveys a current of infinitely small strength. If, then, these filaments are taken by such a rule that the cross-section of the filament *on which* P *actually lies* is zero, the current running in this filament is zero, so that the expression

$$\frac{\text{current in filament}}{\text{perp. from P on filament}}$$

is not infinite; and obviously this is the only legitimate method of calculation. Similar instances occur perpetually throughout the theory of attraction. Thus, if B A (Fig. 1) is a homogeneous and uniform bar, attracting according to the Newtonian law, and a unit mass is placed at P, we know that the attraction at P is proportional to

$$\frac{1}{p} \cdot \sin \frac{\mathrm{APB}}{2},$$

which is infinity if P is on the bar, whereas it is evident to common sense that the force cannot be infinite. In this case also the true value of the force at P must be obtained by breaking up the bar into infinitely thin filaments.

Now, in the present case, let Fig. 2 represent an enlarged view of the cross-section of the wire B A, its centre being O, its radius being a, and the distance P O being c. Draw P Q R making the angle θ with O P; take any point, S on P R; let $\mathrm{PS} = r$, and construct the usual element of area $r\,dr\,d\theta$ at S by drawing P Q′ R′ inclined at $d\theta$ to P Q R, &c. If i is the total current passing through the whole cross-section, the quantity passing through the element at S is

$$\frac{i}{\pi a^2}\, r\,dr\,d\theta,$$

and if P is so close to the wire that the extremities of the filament whose cross-section is $r\,dr\,d\theta$ are very distant from P, the extreme angles A, B in (2) for this filament are practically zero, so that the force at P due to this filament is, by (2),

$$\frac{2i}{\pi a^2}\, dr\,d\theta.$$

This acts perpendicularly to S P, and as the perpendicular to O P at P is the direction of the resultant force due to the whole current, we must take the component in this latter direction, multiplying the result by 2 because the semicircle below O P gives the same result as that above O P. Thus, then, the whole force at P is

$$\frac{4i}{\pi a^2}\iint \cos\theta\,d\theta\,dr, \quad . \quad . \quad . \quad . \quad . \quad (3)$$

in which we first integrate from $r = \mathrm{PQ}$ to $r = \mathrm{PR}$, so as to get the effect due to the strip Q Q′ R′ R; and then integrate from $\theta = 0$ to $\theta = \sin^{-1}\frac{a}{c}$, the latter corresponding to the tangent from P to the circle. Now $\int dr = \mathrm{RP} - \mathrm{QP} = 2\sqrt{a^2 - c^2\sin^2\theta}$, and the force is

$$\frac{8i}{\pi a^2}\int \sqrt{a^2 - c^2\sin^2\theta}\,.\cos\theta\,d\theta = \frac{2i}{c}, \quad . \quad . \quad (4)$$

which, therefore, is the true value of the force-intensity at P. Hence, if P is actually *on* the wire, the force is $\frac{2i}{a}$, which is far from being infinite.

It follows therefore from (4) that when P is close to the wire, as in Fig. 3, *the whole current* i *may be considered to be condensed into an infinitely thin filament coinciding with the central axis of the wire*, and that for a wire bent into the form of a rectangle we may consider the actual physical wire to be replaced by *a mere Euclidian rectangle coinciding with the core of the wire*, and represented by the dotted lines in Fig. 3. It is here assumed, of course, that the density of the current is the same at all points in the cross-section of the wire—which will not be true at corners or bends. Except in the case of a *straight* wire, it is not strictly allowable to replace the actual current by one of the same strength flowing along the central core of the wire, although this mistake is often made.

Thus, then, for any point P close to the wire, but not near a corner, the expression

$$i\,\Sigma\frac{1}{p}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

previously given in (5) (see *The Electrician*, September 6th) for the force holds if we use the rectangular core of the wire as the rectangle A B C D in Fig. 2.

It may be worth while to point out that the expression (5), or (5) (see *The Electrician*, September 6th) which we have deduced by the potential method, follows from the more elementary application of the result (2). For, in Fig. 1 (see *The Electrician*, September 6th), consider the force-intensity at any point Q. Let the angles $\mathrm{QAB} = \alpha$, $\mathrm{QBA} = \beta$, $\mathrm{QCD} = \gamma$,

Digitized by Google

Q D C $=\delta$; then the sum of the forces at Q due to the currents in the sides of the rectangle is i multiplied by

$$\frac{\cos\alpha+\cos\beta}{QR}+\frac{\sin\beta+\sin\gamma}{QM}+\frac{\cos\gamma+\cos\delta}{QS}+\frac{\sin\delta+\sin\alpha}{QL}; \quad (6)$$

and taking the two terms in α, we have $\dfrac{QL\cos\alpha+QR\sin\alpha}{QR\,.\,QL}$ of which the numerator is evidently equal to Q A, so that this term is equal to the reciprocal of the perpendicular from Q on the line L R. Similarly for the other terms in (6), and thus the expression (5) is deduced.

The same application of (2) to the case of a current i running in any *triangle* A B C easily gives the force-intensity at any point P in the plane of the triangle equal to

$$i\left(\frac{\sin A}{p_1}+\frac{\sin B}{p_2}+\frac{\sin C}{p_3}\right), \quad . \quad . \quad . \quad (7)$$

in which p_1, p_2, p_3 are thus defined: from P let fall P L, P M, P N perpendicular to B C, C A, A B, respectively; then p_1 is the perpendicular from P on M N, p_2 on N L, p_3 on L M.

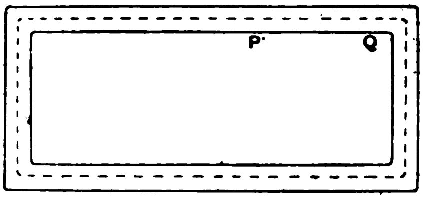

Fig. 3.

Returning to the rectangular current, if the point P in Fig. 3 is taken near a corner, as at Q, the case requires a special examination, and the replacement of the wire by its central rectangular core is not strictly justifiable. The result (5) (see *The Electrician*, September 6th), together with the graphic method, will still, however, be approximately correct, as we shall see.

Let us suppose Q to be actually on the wire at the corner and in the plane of the central rectangular core (dotted line in Fig 3). Then if p is the length of the perpendicular from a corner of this rectangle on the opposite diagonal, the expression (5) gives the force at Q equal to

$$i\left(\frac{1}{p}+\frac{2}{a}+\frac{\sqrt{2}}{a}\right), \quad . \quad . \quad . \quad . \quad . \quad (8)$$

of which the first term is negligible in comparison with the others. Now, if the lines of flow in the wire could be assumed

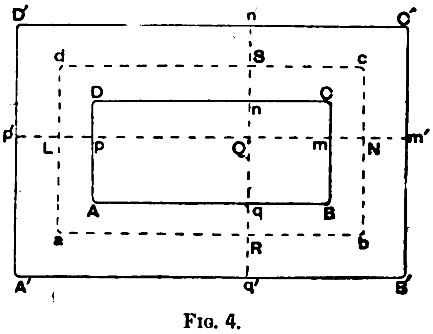

Fig. 4.

to be rectangles, *even at the corners*, the force at Q due to that part of the current which lies in the corner—*i.e.*, the part cut off by two planes at Q parallel to the sides of the rectangle and perpendicular to the plane of Fig. 3—is found without difficulty to be $\dfrac{4\,i}{\pi a}$, and the total force at Q would be, on this supposition,

$$i\left(\frac{1}{p}+\frac{2}{a}+\frac{4}{\pi a}\right), \quad . \quad . \quad . \quad . \quad . \quad (9)$$

which is somewhat less than (8), and evidently less than the true value, since the tubes of flow round the corner at Q are curved and not portions of rectangles; and since, moreover, the current density in these tubes will be greater near Q than in the tubes lying near the outside of the corner.

It would appear, then, that, in the absence of an accurate calculation founded on a knowledge of the lines of flow round the corners, the expression (8), or (5), and the graphic construction previously given, may be accepted as sufficiently accurate even for points very close to the corners. (I do not know whether or not the nature of the lines of flow round the bends, together with the current densities in them, have been investigated. Possibly Mr. Heaviside may have considered this matter.)

Take now the case of a flat rectangular coil, Fig. 4, consisting of any number, n, of rectangular windings, the innermost being the rectangle A B C D, and the outermost A′ B′ C′ D′. Let the diameter of the wire be h (a small quantity); let Q be any point in the plane of the coil; from Q let fall perpendiculars on the sides, meeting them in points m, m', n, n', &c.; let $Qm=\alpha$, $Qn=\beta$, $Qm'=\alpha'$, $Qn'=\beta'$, &c. Now take any rectangular current, $a\,b\,c\,d$, of the series; let $mN=nS=x$; then if p is the length of the perpendicular from Q on N S, we have

$$\frac{1}{p}=\frac{\sqrt{(\alpha+x)^2+(\beta+x)^2}}{(\alpha+x)(\beta+x)}, \quad . \quad . \quad . \quad . \quad (10)$$

and the contribution to the expression (5), or (5) (see *The Electrician*, September 6th), given by the portion $m\,m'$ C′ $n'\,n$ C of the coil will be obtained by giving x in (10) the values $0, h, 2h, 3h, \ldots (n-1)h$. (By each rectangle, $a\,b\,c\,d$, we understand strictly the *central core* of the corresponding winding.) There will, of course, be similar expressions for the contributions of the other gnomons, $n\,n'$ D′ $p'\,p$ D, &c.

Now we may calculate only the portion due to the first gnomon, and this will be typical of the rest; and it is obvious from the elements of the integral calculus that $\Sigma\frac{1}{p}$ for this gnomon, multiplied by h, will be the integral of the expression at the right-hand of (10) from $x=0$ to $x=m\,m'$. Denoting $\Sigma\frac{1}{p}$ for this part of the coil by f, we have, then,

$$f=\frac{1}{h}\int_0^b\frac{\sqrt{(\alpha+x)^2+(\beta+x)^2}}{(\alpha+x)(\beta+x)}\,.\,dx, \quad . \quad . \quad (11)$$

where $b=m\,m'=$ breadth of the coil.

This integral can be found in various ways. Thus, if we put $\alpha+x=(\beta+x)\tan\theta$, it becomes

$$\int\frac{d\theta}{\sin\theta\cos\theta(\cos\theta-\sin\theta)},$$

which is the same as

$$\int\left(\frac{d\theta}{\sin\theta}-\frac{d\theta}{\cos\theta}+\frac{2\,d\theta}{\cos\theta-\sin\theta}\right),$$

or

$$\int\frac{d\theta}{\sin\theta}+\int\frac{d\phi}{\sin\phi}+2\int\frac{d\theta}{\cos\theta-\sin\theta}, \quad . \quad . \quad (12)$$

where $\phi=\frac{\pi}{2}-\theta$; and obviously $\theta=SQc$, $\phi=NQc$. The first two of these integrals give $\log_e\tan\frac{\theta}{2}\tan\frac{\phi}{2}$, while the third is $-\sqrt{2}\log_e\tan\left(\frac{\pi}{8}-\frac{\theta}{2}\right)$.

This last integral in very inconvenient, because if Q is such that $\theta=\frac{\pi}{4}$ it gives us an infinite term to deal with, and obscures the true result. Hence in the last integral in (12) we shall use the original x instead of θ. Doing this, we have

$$\frac{d\theta}{\cos\theta-\sin\theta}=\frac{dx}{\sqrt{(\alpha+x)^2+(\beta+x)^2}}$$

$$=\frac{1}{\sqrt{2}}\cdot\frac{dx}{\sqrt{\left(x+\frac{\alpha+\beta}{2}\right)^2+\left(\frac{\alpha-\beta}{2}\right)^2}}$$

$$=\frac{1}{\sqrt{2}}\log_e\left\{x+\frac{\alpha+\beta}{2}+\frac{1}{\sqrt{2}}\sqrt{(x+\alpha)^2+(x+\beta)^2}\right\}$$

$$=\frac{1}{\sqrt{2}}\log_e(QN+QS+\sqrt{2}\,.\,Qc), \quad . \quad . \quad (13)$$

Digitized by Google

since $\frac{1}{\sqrt{2}}\log 2$ is merely a constant which disappears in the integration between limits.

Again, by elementary trigonometry $\tan\frac{\theta}{2}\tan\frac{\phi}{2}=\frac{a+\beta-r}{a+\beta+r}$, where $r=Qc$; so that we have

$$f=\frac{1}{h}\left\{\log_e\frac{a+\beta-r}{a+\beta+r}+\sqrt{2}\log_e(a+\beta+r\sqrt{2})\right\}, \quad . \quad (14)$$

in which the term in brackets is to be taken between the limits denoted by the rectangle $Q\,m\,C\,n$ and the rectangle $Q\,m'\,C'\,n'$.

Hence, then, if we take the other gnomons of the figure, and denote the product of the four values of $\frac{a+\beta-r}{a+\beta+r}$ given by the inner boundary A B C D by $\Pi\frac{a+\beta-r}{a+\beta+r}$, the total force at Q produced by a current of strength i flowing in each winding of the coil is obtained by taking the value of the expression

$$\frac{n\,.\,i}{b}\left\{\log_e\Pi\frac{a+\beta-r}{a+\beta+r}+\sqrt{2}\log_e\Pi(a+\beta+r\sqrt{2})\right\} \quad (15)$$

for the outer rectangle A′ B′ C′ D′ and its value for the inner, A B C D, and subtracting the one from the other. (Thus, for example, the second term in (15) means, for the inner rectangle, $\sqrt{2}\log(Qm+mC+QC\sqrt{2})\,(Qp+pD+QD\sqrt{2})\,(Qq+qA+QA\sqrt{2})\,(Qq+qB+QB\sqrt{2})$, with a similar meaning for the first. These terms occupy much more space in writing out in symbols than they do in actual numerical calculation when the lengths $Q\,m$, $Q\,n$, &c., are numerically assigned.)

In actual numerical work we shall use logs to base 10 instead of logs to base e, and then the multiplier outside the bracket in (15) will be $2{\cdot}302\frac{n\,.\,i}{b}$.

The result at which we have arrived will be more accurate, of course, the smaller the diameter of the wire in the coil and the thinner the insulating coating, since the process of *integrating* (10) will be the more allowable.

Obviously at the centre of a square coil the first term in (15) contributes nothing to the result, since it is the same for the outer as for the inner boundary of the coil.

To calculate the force, then, we require nothing but the easily measurable lengths $Q\,m'$, $Q\,n'$, &c., the breadth b of the coil, and the simplest use of a table of logarithms.

MOLECULAR ELECTRICITY.

BY J. H. POYNTING, SC.D., F.R.S.

(Continued from page 671.)

We must now attempt to give some account of the action at the source of a voltaic current. As we simplified the electrolyte so we shall simplify the active liquid of the voltaic cell by imagining that we have merely sulphuric acid, that is, we shall neglect the solvent, water. We shall take as the two metals zinc and copper.

We know that the result of putting the copper and zinc in the acid is that the air above the acid tends to become the seat of tubes of induction running from copper to zinc. This will be neutralised by the oxidising tendency of the air on the zinc—at any rate that is the "chemical theory" of voltaic action. To eliminate this action of the air we shall suppose the zinc to have a copper terminal in the air, as it always has in practice. Experiment shows that these tubes of induction always run from copper terminal to zinc terminal with a fall of potential which may be as much, say, as a volt and a half. To represent the establishment of this induction let us imagine the cell initially to consist of such molecules as are shown in Fig. 9 (a), where we represent the acid molecules as consisting of $+H_2$ paired with $-SO_4$, and the copper and zinc plates as $\pm$Cu and $\pm$Zn.

Of course, the molecules in each substance are evenly distributed in all directions, but only those are shown in the figure which are suitably directed for the action which is going to occur. The first stage is represented in Fig. 9 (b), where change of partners has occurred between metal and acid both with copper and zinc. The H_2Zn molecules do not reverse, for it is an experimental fact that the hydrogen does not rise up where it is first turned out. The reversal may perhaps be prevented by the presence of the $ZnSO_4$ molecules, but it is

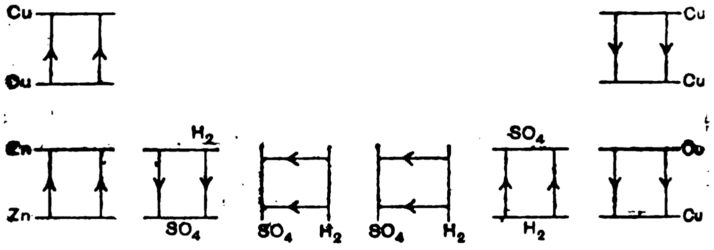

FIG. 9a.

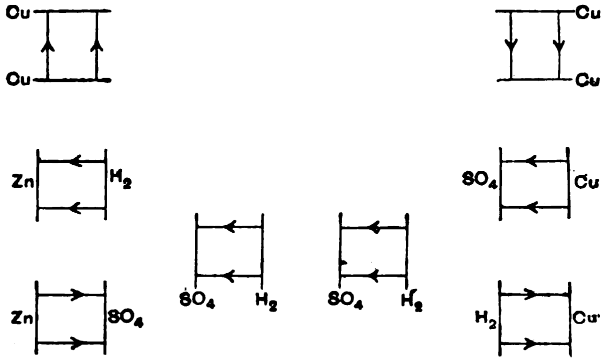

FIG. 9b.

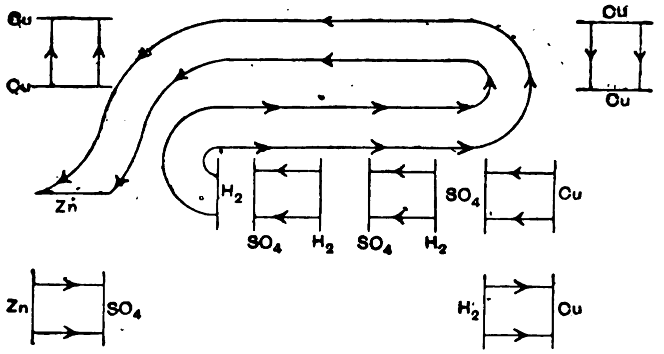

FIG. 9c.

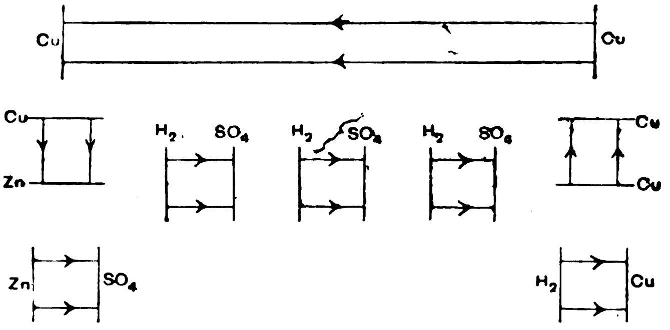

FIG. 9d.

more probably due to the electrical energy put into the H_2Zn. For the $ZnSO_4$ contains much less energy than the H_2SO_4 it replaces; so that the H_2Zn contains much more than the ZnZn it replaces. The electrical energy put in makes the atoms separate too widely, we may imagine, to allow of the contact needed for reversal. Probably at first there is no reversal in the H_2Cu molecules at the other plate, and for similar reasons.

Digitized by Google

The electrical energy in the H_2Zn and H_2Cu molecules will imply that the acid is at a higher potential than the metals and tubes of induction will spread out from the H_2 atoms. Since the H_2Zn molecules contain the most energy, we may represent their tubes as spreading rather than those of the H_2Cu, and in Fig. 9 (*c*) we have the tubes shown as going out towards the copper and then doubling back again. In (*d*) the tubes have entered into the neighbouring molecules by coalescence with oppositely-directed tubes, and we are left with two tubes running from the + to the − terminal with a $ZnSO_4$ molecule and an H_2Cu molecule, the $CuSO_4$ molecule having been dissociated in the process. The molecules of acid have changed partners, but still have the same constitution.

If the action is not continuous, but merely goes on till the terminals are charged, we must suppose that H_2Zn and H_2Cu pairs are left against each plate with an average fall from H to metal of, say, $1\frac{1}{2}$ volts. The pairs against the copper plate are no doubt the agents in polarisation. The reverse current which we get on replacing the zinc by a fresh copper is to be set down to the straying out of the tubes of induction of these H_2Cu pairs. If the action is made continuous by connecting the terminals with a wire, the hydrogen rises up from the copper plate, and we must suppose that half the H_2Cu pairs have reversed and have then changed partners with the other half. Perhaps this reversal is rendered possible by the resolving of the $CuSO_4$ molecules, perhaps by the outlet provided for the energy of the H_2Cu pairs in the external circuit.

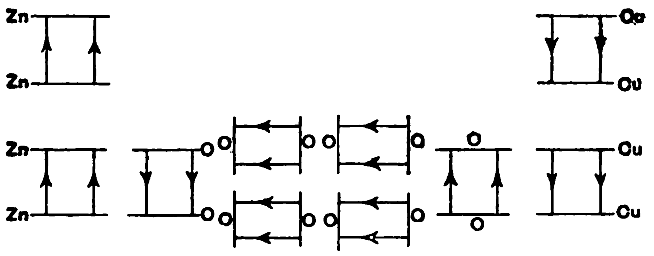

FIG. 10*a*.

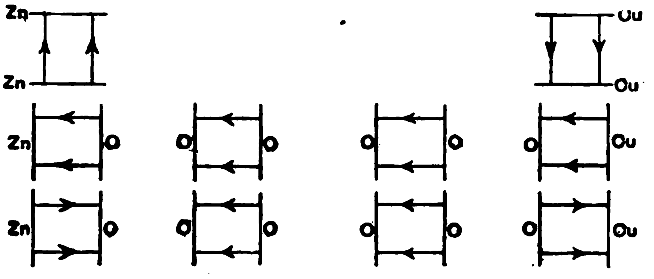

FIG. 10*b*.

In a very similar way we may account for the contact difference of potential of copper and zinc in air. We know that if the two metals are brought into contact a fall of potential occurs from the air near the zinc to the air near the copper; that is, electric induction passes from the neighbourhood of one to the neighbourhood of the other. Both metals can be oxidised, but zinc by far the more readily. Let us suppose the oxygen molecules in the air to be made up of pairs of opposite atoms, and that *before contact* we have a state of affairs, represented by Fig. 10 (*a*), developing into (*b*) by the actions at the metals. On each metal we have the normal oxides ZnO CuO where the positive atom comes first, and the unstable molecules OZn and OCu. If the tubes of induction of these unstable molecules stray out they have to double back on themselves, so that as long as there is no contact there are equal numbers in the two directions passing through the air, and no fall of potential except from the surface layer of the air to the surface layer of the metal close to it. This fall will be greater at the zinc than at the copper, since there is presumably more energy given up at the zinc surface. Probably reversal is prevented either by the presence of the normal oxides or by the want of outlet for the energy. If, however, it does occur in some of the unstable molecule there will be re-pairings and the formation of new metal molecules and new oxygen molecules, with the net result that each metal is left slightly oxidised. But let us make the two metals touch as at J in Fig. 11 (*a*). If the tubes of induction of the OZn molecule now move out like those of the H_2Zn molecule in Fig. 9 (*c*) the upper returning part can enter into the continuous metal bridge and there be dissipated; while the lower outgoing part will thread the oxygen molecules, as shown in Fig. 11 (*b*), and decompose the CuO molecule already found. We shall as a net result have ZnO on the surface of the zinc, a fall of potential from O on the zinc surface to O on the copper surface, and the unstable OCu, which possibly reverses and re-pairs, leaving the copper surface unacted on. If it remains then the copper is polarised, and if the zinc were suddenly removed and replaced by a new copper it would appear that the old copper should show a fall of potential towards the new. But any such

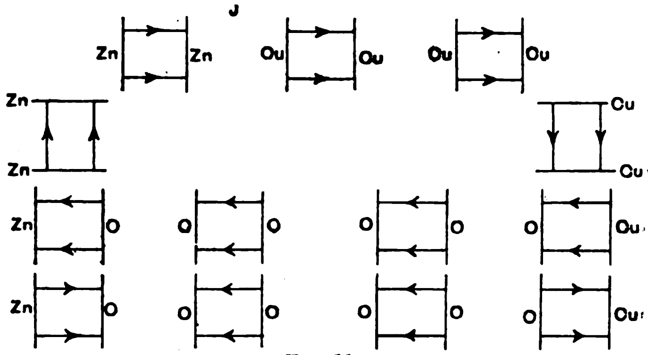

FIG. 11*a*.

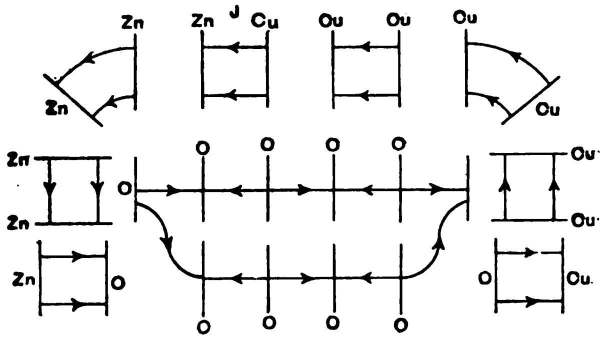

FIG. 11*b*.

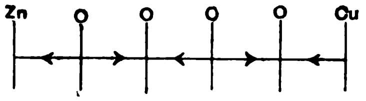

FIG. 11*c*.

fall would probably be disguised by the induction ending in the O atoms next to the copper. We have probably gone too ar in this account in supposing that *all* the induction of the OZn molecules goes out in this way. If, for example, we suppose that only half goes out, we get a chain extending from Zn to Cu, as in Fig. 11c. Probably some such supposition must be made in order to explain how the +O atoms remain at the zinc surface and the −O atoms at the copper surface after the break of contact. That they do remain is shown by the + electrification of the zinc and the − of the copper when tested by an electrometer. But our account must be regarded as a first attempt and not a complete explanation.

Leaving electrolysis, let us consider how an ordinary insulator may be affected by induction, and how we may represent the condition of affairs leading up to spark discharge. We shall thus get some useful ideas which will supplement our account of electrolysis and make it somewhat easier to understand the true nature of the process.

We shall suppose that we are dealing with a dielectric consisting of paired + and − atoms, and we shall suppose, further, that these molecules are initially self-contained—that is to say, that their tubes do not stray out to surrounding molecules. This is, no doubt, a simplification not existing in nature; but, as with electrolysis, so here also we must be content to begin

Digitized by Google

with an abstract case. When there is no apparent electrification in the system the axes of the molecules will be equally distributed in all directions. But if electrification is communicated to a pair of conductors bounding the dielectric, tubes of induction move into the dielectric, and, selecting the suitably arranged molecules, connect these in chains. It will be convenient now to suppose at least four tubes of induction to pass from atom to atom in a molecule. Let Fig. 12 (*a*) represent a number of molecules ready for a tube of induction to affect them. In (*b*) it has moved in and formed the molecules into a chain stretching right through the dielectric. If we suppose another tube to move in, as in (*c*), we get a condition of instability, for now we are just half-way to a change of partners all along the line. A third tube will give

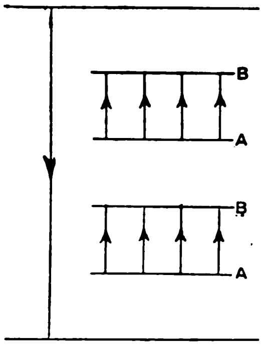

Fig. 12*a*.

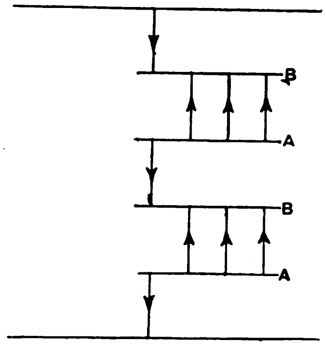

Fig. 12*b*.

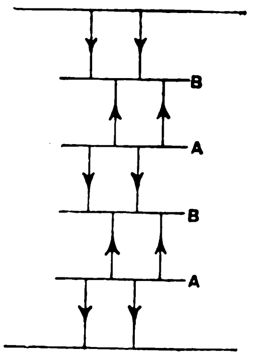

Fig. 12*c*.

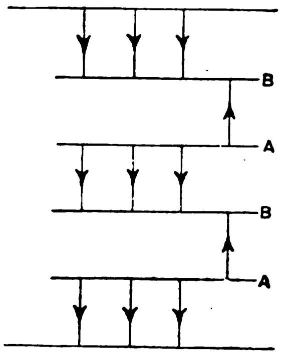

Fig. 12*d*.

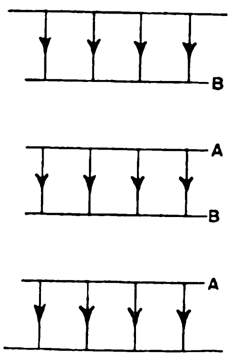

Fig. 12*e*.

us (*d*), a configuration with the same amount of energy as (*b*), since the molecules in the two cases are similar, the axes only being reversed. Hence in passing from (*c*) to (*d*) energy is given up, another way of saying that (*c*) is unstable. A fourth line entering will change (*d*) to (*e*), where the change of partners is complete, and where electrolysis has occurred.

We may usefully follow out the process by the aid of a diagram representing the relation between energy put in and induction. Beginning with an ordinary condenser, let distances along O X (Fig. 13) represent induction put in per unit area cross-section, distances along O Y difference of potential between the end plates.

At first we have

$$V = \frac{4\pi \sigma d}{K},$$

where V is the potential difference, *d* the thickness, σ the surface density, and K the specific inductive capacity.

But since the induction $D = \sigma$,

$$V = \frac{4\pi d}{K} D.$$

If then K is constant, the relation between V and D is represented by a straight line, which makes with O X an angle θ, given by

$$\tan \theta = \frac{4\pi d}{K}.$$

The energy stored per unit cross-section is equal to $\frac{\sigma V}{2}$, or equal to the area from the origin up to the ordinate V, and bounded by the line representing the relation between V and D. We may indeed regard the diagram as showing the relation between induction and energy stored, and this is probably a better point of view, since we cannot attach much idea to potential in the later parts of the process now to be considered. From this point of view the abscissa is the induction through unit area and the ordinate is the energy added per unit addition of induction.

All experiments hitherto made appear to show that K *is* practically constant so long as the medium can continue to store up energy, though the Kerr effect shows that K does alter slightly as D increases, apparently sometimes increasing

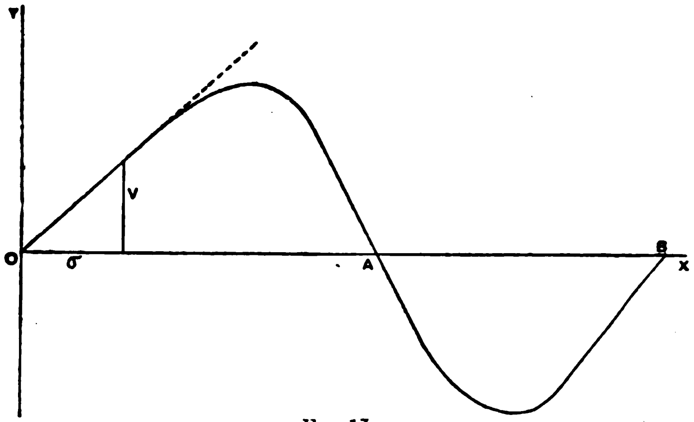

Fig. 13.

and sometimes diminishing, or, perhaps, always increasing, but sometimes most along the lines of induction, at other times most at right angles to them.

Sooner or later, however, a point of instability is reached —sooner in gases, later in liquids and solids; and discharge occurs along one track and all the energy is dissipated. We can see how the curve in Fig. 13 must run in order to represent this instability. Making the unit area small enough to represent the cross-section of a molecule, the curve expresses the relation between induction going right through a chain of molecules from plate to plate and energy put in. At first, while only a small part of the induction is continuous, as in Fig. 12 (*b*), we know that the energy stored is proportional to the square of the induction, and the curve is, as we have seen, a straight line. But as more induction becomes continuous from plate to plate, and as the atoms are pulled in both ways, the force resisting separation does not go on increasing so rapidly, and the curve falls below a straight line.

At some point on the way to instability and subsequent change of partners the force will reach a maximum, and after that the curve will turn down, successive equal additions of induction requiring diminishing additions of energy. At last, when the lines of induction from each atom run half one way, half the other, as in Fig. 12 (*c*), the energy put in is a maximum, and the curve crosses the X axis, as at A. The configuration is now unstable, and will of itself pass through (*d*) and (*e*), absorbing two more positive lines or extruding two negative lines till we arrive at (*e*), represented by the point B on the

Digitized by Google

diagram, when the condition is again stable, like that at the beginning. The energy put in between O and A is given out again between A and B in part, no doubt, as the light, heat, and so on of the discharge. The curve O A B may be termed, perhaps, a molecular characteristic. It should be noted that the passage from (*c*) to (*d*) (Fig. 12), or past A (Fig. 13), may be effected either by absorbing more positive tubes, or by sending out negative tubes. If the passage through the position A occurs with a rush then we may regard the chain as sending out negative tubes by some such process as is illustrated in Fig. 14 (*a* to *d*). Though the instability of a single chain will not be reached till its condition is represented by A (Fig. 13), the instability for a great number of parallel chains is reached as soon as they are all at or near the highest point of the characteristic. In the ascending part of the curve all the parallel chains will tend to have the same amount of induction through them, for if any one has more than another, energy will be yielded up by a redistribution between them. Thus let one chain have induction O M (Fig. 15), another near it induction O N, the energies stored being O M P, O N Q. If L bisect M N the second chain may give up induction L N = L M to the first, and at the same time there will be a yield of energy equal to the difference

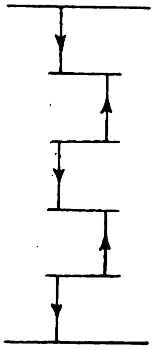

Fig. 14*a*.

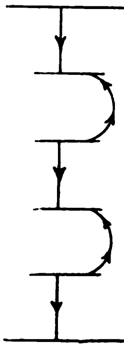

Fig. 14*b*.

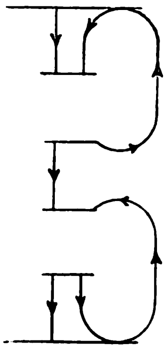

Fig. 14*c*.

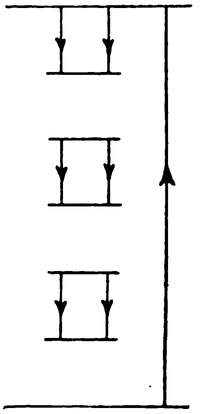

Fig. 14*d*.

between the areas P L and Q L. Probably the induction is really distributed about an average, some of the chains having more, others less, for no doubt the condition is kinetic, and when there appears to be equilibrium it is not static but "mobile."

If the average condition is represented by a point far up the slope and near the crest, and if any one of the chains gets past the crest, as far below it on the other side as the average is below on the first slope, then this advanced chain will at once receive induction from the others, and continue to move down the second slope towards the point of unstability. Thus, let there be n chains in all. Let O H A (Fig. 16) be the characteristic of that with the greatest induction, O K A^1 the sum of the other $n-1$ characteristics. If the first chain is at P while the others are at p on the same level, by a transfer of induction mn = M N from the general body in the first chain, there is a yield of energy, since the area of $p\,m\,n\,q$ is greater than the area of P M N Q, for the two slips are of the same breadth, but the slope of P Q is steeper than that of $p\,q$. The transfer will therefore take place, and the chain moves from P to Q. At Q, *à fortiori*, a new transfer will take place, and so on, and the chain will move towards the position of instability. This will all probably occur even when the average is far below the crest if the induction is widely distributed about that average, for as soon as one chain gets over the crest it will probably find others between it and the average ready to hand on their induction and energy to it, and send it down the second slope.

As, then, the general average rises towards the crest, the most advanced chains, as soon as they pass the crest, tend to discharge the rest, and there will at a certain point be a rush in sideways on to these advanced tubes. They will move down to the condition of instability represented by A on the diagram. They can of themselves move past this point, extruding negative tubes, till they arrive at the point B, where the change of partners is complete.

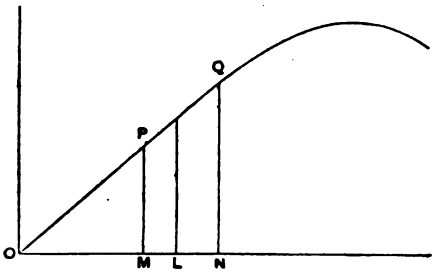

Fig. 15.

It appears at least probable that this yield of negative tubes gives the opposite charging of the medium which takes place in the second quarter period of the oscillation accompanying rapid discharge, now made so familiar by the work of Hertz. We may, perhaps, think of the process somewhat as follows: If the inrush of positive tubes during the first stage is rapid they will concentrate on the chains in the neighbourhood of that which began the breakdown, and carry them past the unstable point. Then will begin the outrush of negative tubes, and when this is complete the central chains will be discharged and in the condition of Fig. 12 (*e*), while the surrounding medium will contain negative induction. There will be now an inrush of negative induction into the *locus* of

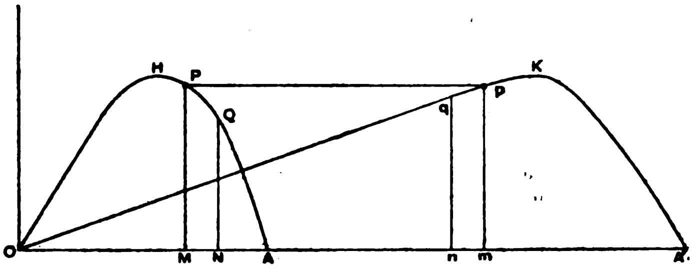

Fig. 16.

the first discharge, for not only is this free from induction, but also its molecules are suitably arranged to take up negative tubes, and during the second half-period of swing from negative to positive there will be a second change of partners along the same line. And so on with the successive alternations of charge, and there is a tendency, evidently, to keep the same line of discharge. Each change will give atoms at the two end plates, which will combine either with each other or with the electrodes, or perhaps be taken again into the chains in the following changes. In the sudden changes of partners some of the energy goes to atomic vibration, and we have evidence of this in the atomic radiation which we call spark. There is also energy of translation of the atoms from one partner to another, which appears as heat in the molecules. This heat possibly produces the sound of the spark through the sudden expansion. We have then dissipation of energy as well as the radiation out to space in the Hertzian waves, and the two gradually reduce the electrical energy of the system.

Digitized by Google

We can see, too, how the amplitude of charge may lessen in the process. For if the negative tubes begin to move out at the middle of each oscillation before the positive tubes have all moved in, or *vice versâ*, then the first of the issuing kind will destroy the last of the incoming kind, and the final charge will be diminished by the amount of this overlap. In the extreme case of slow discharge, as through a wet thread, the issuing tubes are neutralised as they come out by the incoming ones, and the motion is dead beat.

These negative tubes turned out may also supply the negative tubes required in the theory of Prof. J. J. Thomson ("Recent Researches," Chapter I.).

(*To be concluded*)

THE VELOCITY OF ELECTRIC WAVES.*

BY JOHN TROWBRIDGE AND WILLIAM DUANE.

The direct determination of a velocity implies the measurement of a length and of a time. So far as we know, no direct measurement of the velocity of electric waves has been hitherto published. A number of experiments have been performed on the velocity of single pulses of electricity travelling over long metallic circuits by Wheatstone, Fizeau and Gounelle, Siemens, Blondlot† and others, but the results obtained are very discordant. Blondlot's method is not open to the objections that have been raised against some of the others, for his electric pulses theoretically were short, and had steep wave fronts. Blondlot‡ also described a method of determining the velocity of a system of electric waves. He measured the distance between the nodes on a metallic circuit, but, in order to get the time, he calculated the period of oscillation of another circuit that was in resonance with the first. His determination, therefore, was not a direct measurement.

Early last year the following direct method of measuring the velocity of electric waves suggested itself to us:—Increase the size, and, if necessary, change the shape of a Hertz vibrator until the period of oscillation is sufficiently long to be determined by photographing the spark; measure the length of the waves induced in a secondary circuit tuned to resonance with the vibrator; and the quotient of the wave-length by the time of a complete oscillation will be the required velocity.

The first apparatus experimented with was that used by Mr. St. John in investigating the peculiarities of waves along iron wires. For a detailed description of this apparatus see the *Philosophical Magazine* for November, 1894. It has been assumed by certain writers that the reaction between the circuits, arranged in the manner employed by Mr. St. John, is, to a large extent, what would be called in the older theory of electricity electromagnetic rather than electrostatic. Certain phenomena, however, which appeared in the early part of our investigation seemed to point to the view that the greater portion of the action was electrostatic; and we therefore concluded to arrange the apparatus so that the reaction should be wholly electrostatic, thinking by this means to obtain a more powerful oscillation and a more regular wave than with the electromagnetic arrangement described and used so successfully by Blondlot. The first attempt arranged on the electrostatic principle proved a complete failure. A second trial about a fortnight later, however, was so successful that we fully determined to adopt the electrostatic method.

The first point in the course of the investigation worth detailed description is the production of electric waves along parallel wires in such a manner that they are actually visible to the eye. The arrangement of the apparatus to accomplish this was as follows:—

A primary condenser, A B (Fig. 1), was held with its plates in vertical planes by means of suitable wooden supports (not represented in the figure), and was joined in a circuit, B C, consisting of two wires about 75cm. long, placed 4cm. apart. In reality this circuit B C should be represented as perpendicular to the plane of the paper (which is taken as the horizontal plane passing through the centre of the apparatus). The plates of the condenser A B were sheets of tinfoil 101 × 40cm. glued to hard-rubber sheets, and the dielectric between them consisted of other similar sheets of hard rubber sufficient in number and thickness to make the distance between the condenser plates 4·2cm. Outside the primary condenser plates and separated from them by hard-rubber plates (total thickness 0·6cm.) were two secondary plates, E and F, each 40cm. square. To these plates was attached the secondary circuit E G J H F, the form of which is represented in the figure. This latter circuit consisted of copper wire, diameter 0·13cm., and its total length from E to F was 4,200cm. A spark-gap with spherical terminals 2·5cm. in diameter was placed at C in the primary circuit, and another spark-gap with pointed terminals was sometimes inserted at J in the secondary circuit, although this latter spark-gap had no effect upon the phenomena to be described. The primary condenser was charged by means of a large Ruhmkorf coil excited by five storage cells with a total voltage of ten volts. The current from these cells was made and broken by the automatic interrupter used by Mr. St. John and described by him in his Paper above referred to. Every time the primary condenser was charged a spark passed at C, causing an oscillatory discharge. A convenient method of forming a mental picture of the oscillation excited in the secondary circuit is the conception of Faraday tubes elaborated by J. J. Thomson, in his "Recent Researches in Electricity and Magnetism." The oscillations of the primary acted inductively upon the secondary and sent out groups of Faraday tubes which travelled along the secondary circuit, with their ends on the wires, and lying chiefly in the space between them. At the end J they reversed their direction and travelled back along the circuit. The period of oscillation of the primary circuit was altered, until by trial it was found that groups of returning tubes met groups of advancing tubes between the points G and H. As the two sets of moving tubes were oppositely directed, they annulled each other and produced a node. Thus a system of stationary waves was set up with a node at J, another node at G H, and a ventral segment at K L. The method of discovering when the circuits were in tune and of investigating the shape of the waves will be described later. The point to be noticed here is that the vibrations were sufficiently powerful to cause a luminous discharge on the surface of the wire where the accumulation of tubes was a maximum, *i.e.*, at K L, while at the nodal points J and G H the wire was entirely dark. Still further, the wave formation could be made apparent to the sense of hearing as well as that of sight; for placing the ear within a few centimetres of the wire and walking beside it, a distinct crackling sound could be heard at the points K and L, whereas no such sound could be heard
